Improving Box Edging (J. W. T.).—The correct way to deal with overgrown box edging would be to lift it, tear it apart in small sections, taking care to keep a few roots on each section, at the same time cutting the tops back as far as required. Then dig over the borders, adding a little manure if very poor, tread the borders, lay down a line and chop the margins out with perpendicular or almost perpendicular sides; then lay the small sections of box in the trenches close to the edges of the borders, keeping the tops about 2ins. above the natural level of the dug borders and covering up the roots at once to keep them moist. Tread the soil firmly about the roots and, if the weather is dry, water well. This work can be done at once. If, however, our correspondent is unable to go to this trouble, he may cut the box edging back severely, and new shoots may be expected during the summer. The pruning should be done as early as possible.

Plants for Dry South Bank. (E. B.).—Brooms should be very suitable for such a position, a selection of the best being Cytisuses albus, scoparius, Andreanus, præcox, purpureus and Genista hispanica, also Spartium junceum. The rock roses are another family which thrive in dry sunny positions; six of the best are Cistuses corbariensis, cyprius, ladaniferus, laurifolius, Loreti and Silver Pink. If the position is a warm one, Cistus purpureus would be excellent.

Tree or Shrub for Grey Hedge (C. E. A.)—Two evergreens likely to suit the position described are Cupressus Lawsoniana Silver Queen and Cupressus (Retinospora) pisifera var. squarrosa. Failing these, Atriplex Halimus is a splendid seaside shrub and should give a good silvery effect at Torquay. In the mild climate of the south-west, Teucrium fruticans has the appearance of a greyish-leaved shrub because of the white under-surface, but our correspondent would probably find this too spreading in habit to form a neat hedge.

MISCELLANEOUS.

The Treatment of Heavy Clay Soils (A. B.).—The soil that our correspondent refers to, a portion of a trenched field three years ago, should prove to be a very productive one. Unless a great quantity of lime was applied, over-liming would not result. The lime should do this particular soil much good. Stones, if not very large ones, will not be very detrimental to crops. The ground, now, may need humus; vegetable refuse will supply some if applied in the autumn. Well-rotted manure should be applied now. The humus makes light soils firmer and renders clayey ones more porous, and also helps to retain potash and ammonia in the soil. Use farmyard manure for preference.

Various Questions (A. K. M.).—Rabbits are quite as likely to eat the plants mentioned (Sweet Williams, sunflowers and montbretias) if they are short of food. The dianthi can be grown in pots for flowering in the house, using 4in. or 5in. pots. Use a good sandy loam with lime rubble, and grow in a cold frame. Alpine strawberries can be easily grown for fruiting in pots. For the last shift use a 5in. or 6in. pot, and put three plants in each pot. The best soil is a good loam, to which should be added some well decayed cow manure or guano. When in fruit, feed with liquid cow manure, or artificial manure like Clay's Fertiliser.

Names of Plants.—(A. E. H.).—(1) Saxifraga Stracheyi alba; (2) S. Elizabethæ; (3) S. Petraschii.——(H. V. B.).—Grevillea longifolia.

CORRESPONDENCE

RHODODENDRON TRIFLORUM.

I AM glad to see Mr. Lionel de Rothschild standing up for this rhododendron (page 212). There is no species that flowers more profusely every year, and the colour in one of a good type is quite as good as R. lutescens. Moreover, it starts late in growth, escaping the destruction so often wreaked by frost on the blossoms of R. lutescens, which flowers in February, whereas here R. triflorum defers its display till the latter half of May. The sun shining through a bush 7ft. or 8ft. high lights up the loose bark on the stem with splendid gleams of madder and burnt sienna.—HERBERT MAXWELL, *Monreith*.

DOUBLE YELLOW WALLFLOWER HARPUR CREWE.

IN a recent account of one of the Royal Horticultural Society's Shows this flower is mentioned. I think it may be of interest to know how very ancient this "novelty" is. It has been grown in my gardens for last three generations, but never had a name put to it till of recent years it was "baptised"! This is the best time to put in cuttings, which grow freely, as it has the nature of a shrub, not a seedling, and they grow "like a weed." I do not think there is a better early spring flower than this old-time plant. If any lovers of it wish for cuttings I shall be glad to send some if postage be sent with application.—J. HILL POE, D.L. (Captain), *Riverston Nenagh, Ireland*.

EMPEROR NARCISSUS.

I ENCLOSE a photograph of a basket of narcissi grown from bulbs supplied by Messrs. Robert Sydenham, Limited, Birmingham. These are four bulbs of Trumpet Narcissus Emperor, and these produced fourteen flowers. The bowl has been greatly admired, owing to its richness and profuseness in bloom.

It may be mentioned that the bulbs were English grown. The flowers are borne on long, slender, graceful stems which set them off to advantage.–(MRS.) BENYON, *Moseley, Birmingham*.

A CHARMING BASKET OF NARCISSUS EMPEROR.

A HYBRID EUCRYPHIA.

IT may be of interest to readers of THE GARDEN to see a photograph of a natural hybrid between Eucryphia pinnatifolia and E. cordifolia. This plant was raised by Colonel L. Messel, of Nymans, Handcross, Sussex, from seed taken from Eucryphia cordifolia.

In Colonel Messel's garden there are two old specimen eucryphia trees, one cordifolia and one pinnatifolia, growing side by side. Usually these two plants flower at different times — cordifolia in September and pinnatifolia in August—but in certain years both plants have flowered at the same time, and this hybrid has resulted from the natural cross. The hybrid flowered for the first time on September 6th, 1922, in my garden in Sussex.

The flowers have four petals, as in pinnatifolia, but the leaves, which are evergreen, though more like the leaves of pinnatifolia to look at, are thicker in texture; the leaves also have the curious habit of being both simple and pinnate, even on the same branch.

It is interesting that Eucryphia cordifolia and the hybrid both grow well on a lime soil, and that Eucryphia pinnatifolia does not appear to like lime and has never yet succeeded in my garden.—F. C. STERN.

A HYBRID EUCRYPHIA BETWEEN E. PINNATIFOLIA AND E. CORDIFOLIA.

DAPHNE LAUREOLA AND D. MEZEREUM.

SIR HERBERT MAXWELL is so carefully observant that I have been accustomed to take anything he writes about a plant for gospel. But he is curiously wrong in his repeated assertion (page 212) that the spurge laurel is scentless. Being very susceptible to *nuances* of scent, I have always prized this native plant, and have given it a place in the garden proper because of its distinct and (to me) delightful fragrance—quite a typical daphne scent, but very distinct from that of D. Mezereum. It is true that it is what old writers call "fast" of its scent, *i.e.*, it does not give it out into the air except on very warm, moist evenings. If Sir Herbert will cut a bit and put it in water in a warmish room, I feel sure he will apologise to the plant. It is, of course, possible, though unlikely, that it has lost its scent in its migration to the north. I have never seen bees visit it, nor do they visit D. Mezereum in my garden. But as the spurge laurel exhales its scent at night it is possible that it is fertilised by inconspicuous night-flying or crawling insects.—G. H. ENGLEHEART.

I WAS much interested in the remarks of Sir Herbert Maxwell on the Spurge Laurel, Daphne Laureola, in THE GARDEN, March 29th. The small shrub is rather plentiful in the woods and lanes around here. I gathered the enclosed specimen this morning and think you will find that the flower has quite a strong perfume. This is most noticeable on a sunny day or in a warm room.

Digitized by Google

A friend and I found the plant some years ago, and although not knowing it then, we thought it must be a daphne from its scent.—ELEANORA READING.

[The specimen sent was certainly fragrant.—Ed.]

THE BREAKING OF TULIPS.

THE experiences of Mr. W. A. Watts quoted on page 233 are most interesting, as all efforts to elucidate the mystery of the "break" must be, to those who are devoted to the cultivation of tulips.

The dressing of the bulbs with sulphur would seem to be in the direction of providing an antidote to the attacks of aphides. If it be that breaking is caused by some disease—mosaic or otherwise—and that sucking insects carry the poison when attacking the shoots of the bulbs, the dressing would seem to be an effort in the right direction, as also would insect powder and the spray in keeping down the pests.

Mr. Watts tells us of a number of bulbs which he had dressed with sulphur returning to their self colour again. If this can be established—that is to say if, after a plant has exhibited signs of a break, or a pronounced break, the resultant bulb is dressed with sulphur, the next plant returns to the self colour again—we should have made a definite step in our knowledge of the subject. I have been told of broken flowers reverting to the breeder type, but in my experience broken flowers have never reverted to true breeder type, though sometimes they have come muddled and full of colour, quite different from a true self or breeder.

I will certainly, as an experiment, try what the result of dressing some long-confirmed rectified tulips may be, as Mr. Watts suggests.

Loathing, as I do, the attacks of all aphides, and as "green fly" came over in clouds last year, I fumigated the shed wherein the bulbs were stored once or twice, and kept the bulbs fairly free during their resting stage. The Darwins and the garden tulips did not seem to be attacked at all, or very rarely; the English tulips were a prey to the insects. The harder skins of the former varieties did not seem as attractive to the insects as the softer skins of the English tulips.

Besides bulbs in boxes and on trays, there are bulbs (seedlings) which, after having been dried, are stored in large paper bags and kept free from fly; yet out of these bags come both broken flowers and breeders, even though the broken ones were eliminated from the breeder stocks at taking-up time, and isolated. —C. W. NEEDHAM.

PROLIFIC HYACINTHS.

IN your issue of March 29th Mrs. Coalston draws attention to a hyacinth which produced five blooms. It is impossible to say if this was a freak or if it was a multiflora type which got among the ordinary bulbs in the grower's hands; but it is not such a novelty as her expert friends suggest, although it would have been a few years ago.

Last autumn I got from Messrs. Barr and Sons, London, half a dozen bulbs of a multiflora type of hyacinth; some I potted in ornamental pots, with a layer of pebbles and broken charcoal in the bottom and ordinary potting soil above, the others in 8in. ordinary flower pots, only one bulb in each pot. Five of these produced eight blooms each, the sixth giving only six, but all were beautiful, the colours being as ordered, two a charming light yellow, two a lovely soft pink, and two "heavenly" blue. As we have had a long cold winter they have lasted wonderfully long in bloom—nearly two months. I hope to have more of them for next winter.—D. C. B.

NOTES FROM CONTRIBUTORS

FRITILLARIA PYRENAICA.

SOME people do not care for the fritillarias, but I must confess that they make a strong and strange appeal to me. Some, it is true, are almost weird in their markings and colour tones, but most of them have many points of charm about them, not always visible to the many, but to the well versed these flowers are full of delight and induce them to make many a pause before them, to lift up the bells and revel in the beauty so frequently displayed by the interior of the flowers. I have passed most of the species in commerce—and some not in the trade—through my hands in the garden, and some day I would fain write more about them and their ways, which, candidly speaking, are not always acceptable to those of us who take most pleasure in plants which are almost eternal in their duration of life.

There is, at least, one among the fritillarias of exotic origin which can hold its own well in gardens and which appears to be among those least susceptible to any trouble arising from our climatic conditions. This is F. pyrenaica, the Pyrenean fritillary, which I have occasionally met with in old cottage gardens where it had been from time immemorial, withstanding all the vicissitudes of our weather and the neglect some of these gardens so often experienced. There it sent up its stem to a height of 18ins. or more, bearing flowers of a greenish purple outside, but of most beautiful glossy colouring in the interior, and of exquisite form. It is not a showy flower—the reverse, indeed, is the case—but it is one for the amateur who can see in such flowers points of beauty concealed from the average man. For the inner colouring I cannot do better than quote the description of an able authority who speaks of it as "chequered with purple brown on a yellowish ground." Fritillaria pyrenaica will do in ordinary garden loam, and may be planted in the border or, better still, on rockwork above the level of the eye.—S. ARNOTT.

SPRING TREATMENT OF PEACHES AND NECTARINES.

THE young shoots grow rapidly on trees under glass when the weather is normal outside, even if there is no artificial heat. At this stage very close attention should be given to the daily management—watering, syringing, ventilation and fumigation. These matters cannot be neglected without harm resulting to the trees generally. Then there is the work of thinning out the shoots and the fruits. If more shoots

HOW TO DISBUD AND THIN FRUITS.

are allowed to remain on the branches, resulting in overcrowding, and if the current year's shoots with the buds on them do not mature properly, then the next year's fruit crop is rendered very uncertain. The timely disbudding of the branches allows all those which have been retained ample room to grow in, the majority of the leaves and all the fruits being fully exposed to the maximum amount of light. This exposure from an early stage of the growth of the fruits results in very highly coloured specimens when they ripen. They should be fully exposed when of the size of a hazel nut; then they will at an early date become a bronze-red colour and there will not be any scalding of the skins when ripening. If, however, the fruits are covered by leaves and during the last three or four weeks suddenly exposed to the full sunshine, much damage to the skins may result, and certainly the tempting crimson suffusion of skin will be lacking. So the correct placing of both branch and fruit depends largely upon the way that the disbudding and the thinning out, respectively, is done. Fig. A in the accompanying sketch shows a branch bearing shoots and fruits prior to disbudding. Fig. B shows the same branch properly disbudded and thinned of fruits. All such work should be done gradually, spreading it over a week or ten days to avoid giving a check to growth. The arrows, Nos. 1, 1, point to badly placed fruits, which should be removed. No. 2 is well placed and should be retained. On a branch 18ins. or more in length a young shoot, No. 3, should be retained. On shorter branches two young shoots—the basal and end ones, respectively—will be sufficient. On the current year's shoots, No. 4, bears buds in the axils of the leaves, and these buds will be growth or fruit-buds next year. All small, sappy shoots growing from main branches, No. 5, should be removed entirely. Fig. C shows the approximate size of the fruits at the stoning age—when the stones become hard. During the stoning period, about three weeks, there is not much increase in the size of the fruit, and it is advisable to refrain from unduly exciting the trees by stimulants or extra heat. When the fruits begin to swell after this stage, feeding is an important matter; also syringing and the closing of the house with a moist atmosphere. Not only the fruits but the young shoots should be retained on the upper, not the lower, side of each branch.—G. G.

WIRE NETTING AS A WIND-BREAK IN THE GARDEN.

THE very long spell of exceptionally cold winds has caused plant lovers, generally, much anxiety. Coupled with these winds, the severe night-frosts followed by hot sunshine early, almost every morning, have seared the leaves of many thousands of plants. It has been next to impossible satisfactorily to transplant ordinary plants in many fully-exposed gardens. Our forefathers knew well the beneficial effect of a few branches placed on the north and east sides of young stock at this season. Nine-inch boards, placed on edge, will help materially in guarding tender plants

Digitized by Google

against cold winds. Both boards and branches, evergreen for preference, I have used for many years when a spell of cold winds has prevailed. But I wonder how many cultivators have used fine-mesh wire-netting? Some readers may smile at the idea, I have acquaintances who have laughed outright. From some considerable experience I have proved the idea to be a good one. The fine (½-in.) mesh breaks up the cold currents of air, as it were, and the foliage behind is benefited. On a quite exposed plot the netting should be fixed upright, due north and south and about 15ft. apart if the netting is 2ft. high.

I well remember a garden on the sea coast of Lancashire, near Lancaster, where a hedge of laurustinus failed to grow satisfactorily, and a hedge of this kind was much desired by the owner. It was planted behind a very low wall. A gentleman suggested the wire-netting. The latter was fixed on the wall, and during the first year there was a marked improvement in the growth and appearance of the laurustinus. Soon it reached to the top of the netting, and then the old trouble was repeated.

The winds and fine spray from the sea at this point were strong and injurious to the majority of the plants growing there. The undoubted success of the wire-netting has induced me to use it frequently since, against north and east winds.—HANTS.

POLYANTHUS FROM SEED.

THE name Polyanthus, for the purposes of this note, is taken to include all the ordinary garden primroses, whether the early kinds on single stalks or the later and large bunch-flowering kinds, for the culture will be the same. It is an open question among practical gardeners whether it is better to sow the seed as soon as it is ripe, about the middle of July, or whether to hold it over till the following spring. It is probably a matter for experiment, the proof of which depends on local conditions of soil or climate; it can only be advised that those who are beginning the cultivation of these delightful spring flowers should try both ways and see which is best suited to their own conditions. In my own case I have found spring sowing much the best. The seed, harvested in July, is sown in the early days of February in mild heat; the seedlings are pricked off in the third week of April, either in an uncovered frame or some sheltered bed in the open, and the young plants are put in their places at any suitable time in August. My soil is of the lightest, a poor sand with a trace of peat; it has to be well enriched every year, with cow manure if possible, or with the best substitute that may be procurable. The primroses have a special place, for they are grown in some thousands. Following the indication of the natural homes of the wild primroses, which abound in local copses where there are oaks with an undergrowth of hazel, a place was chosen where there were oaks already, and nuts were planted in such a way as to give some summer shade in those places not reached by the shadow of the trees. It is, of course, necessary to see that the plants are never droughted during any spells of hot weather in the late summer; a copious watering may be necessary two or three times in the season. The falling leaves of oak and hazel are left for a time on the primrose beds, but some are removed if at any time they appear to be lying too heavily. They should be so left that they cover the ground and give the plants some protection, but not so as to smother them. It is useless to put out the large bunch primroses in the wild; they will only answer well to good cultivation. If primroses are wanted in wild ground the common native one is the most suitable and will take care of itself. The early, single-stemmed primroses may be more inclined to succeed in wild places, where there are natural beds of rich humus, than the large bunch kinds, though in consequence of their great variety of form and colour they seem more suitable for garden culture.—GERTRUDE JEKYLL.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

General Work.—The old stems of Brussels sprouts are about finished and should be removed. Dig the ground deeply and afford a liberal dressing of manure. This will do for a crop of potatoes, peas or runner beans. Peas, broad beans, etc., will need hoeing, and it is always advisable to stake peas before they are very far advanced. Runner beans and dwarf beans may be sown in boxes, and the seedlings raised in a cold frame from which frost is excluded. Continue to sow seed of spinach, peas, radishes, lettuce, mustard and cress, also a bed of parsley.

Onions.—The bad weather prevented the hardening off of the plants raised in boxes early in the year, and, consequently, their planting out has been deferred. They ought now to be set out in lines 1ft. apart and 9ins. between the plants. Make the soil fairly firm and deep planting should be avoided. If available, dust the plot over with soot and keep the soil free from weeds by an occasional use of the hoe.

FRUITS UNDER GLASS.

Melons can be successfully grown on a hot-bed, and in a week or two a frame may be spared for this purpose. In the meantime collect the necessary material, viz., leaves and stable manure in equal proportions, and turn over several times to allow most of the rank steam to escape. When making up the bed it should be made fairly firm, but not too hard, and it ought to be a foot or 18ins. larger than the frame. As a rule one plant will be enough for one light, and a small heap of good fibrous loam should be placed in the centre. When the bed is cooling down and the soil is just warm to the hand, it will be safe to put out the plants. Choose an open sunny position for the frame and when damping down early in the afternoon before closing the lights always use tepid water, or the plants may receive a chill. When the weather is bright a little ventilation will be necessary in the early part of the day. During a period of dull weather the frame may not require much air, and no damping down or watering will be needed.

THE FLOWER GARDEN.

Kniphofias, known also as Tritomas, are splendid plants for beds and borders especially such kinds as John Benary, Red Cap, caulescens, and rufa. They enjoy a rich sandy loam, but in most gardens they will succeed. Although they do not require frequent disturbance, the present is a very good time to lift and divide any clumps that are overcrowded and in consequence are producing spikes of inferior quality. Trench the ground and afford a liberal dressing of decayed manure.

Sweet Williams.—Two varieties viz. Scarlet Beauty and Pink Beauty are particularly worthy of wide cultivation, and are well adapted for beds. During the next few weeks seed may be sown in lines in the open ground and when the seedlings are large enough they may be transplanted in rows 1ft. apart.

Sunflowers.—Seed of these is best sown where it is intended for the plants to flower as they do not transplant very successfully.

THE HARDY FRUIT GARDEN.

Apricots.—These will need disbudding, but not so much as peaches. It consists of removing all badly placed growths such as those pointing towards the wall, where they have no chance of making headway, and all foreright shoots which if left would render the tree unshapely. Growth needed for extension should be tied in and allowed to develop, but others should be pinched at the third or fourth leaf. T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.), *Castleford, Chepstow, Gloucestershire.*

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Beetroots.—When favourable weather conditions prevail, thoroughly rake the ground and make fine on the surface. Drills should then be drawn out 2ins. deep and 15ins. apart, and the seed sown thinly therein. The following varieties have held their own for quite a number of years: Dell's Improved Black Leaved, Dobbie's Purple, Nutting's Improved Crimson and Middleton Park.

Cauliflowers.—Plants raised early in the year from seed sown in heat should now be well advanced, and should be set out in liberally manured and deeply cultivated ground. The lines should be 20ins. apart and 15ins. allowed between each plant in the lines.

Peas.—Those in late districts who have raised and forwarded plants under glass should have them planted out, while others in favoured localities will have rows on the early borders ready for staking. Others who have plants growing in pots under glass will have pods ready for pulling. Sutton's Little Marvel is a dwarf-growing variety with dark green leaves and excellent for pot work.

Turnips.—A few drills should be drawn out 15ins. apart and seed of Extra Early Milan sown. Preparations should also be made to have Golden Ball and one or other of the garden swede varieties sown. Swedes should be thinned from 6ins. to 8ins. distant from each other in the lines.

THE FLOWER GARDEN.

Alyssum minimum.—It may not always be convenient to sow this dainty and floriferous hardy annual where the plants are intended to flower, but they can be sown thinly in boxes containing moderately fine soil and raised in gentle warmth. When the young plants are large enough and hardened off, they may be set out directly from the seed boxes. This is really an ideal plant as an edging to beds or borders. There is a variety called Lilac Queen, but it cannot be compared to the beauty of the white-flowered varieties.

Nigella, popularly called love-in-a-mist, has been long in cultivation, yet it may surprise some to know that it belongs to the same Natural Order of plants as our common buttercup. It is an easily grown annual, and the seed should be sown where the plants are intended to bloom. The variety Miss Jekyll is the one most in vogue.

Seeds and Seedlings.—Chrysanthemum inodorum fl. pl. Bridal Robe, marigolds Dwarf Lemon, African Dwarf Orange, Perilla nankinensis and Tagetes Legion of Honour should be sown thinly in boxes of medium fine soil. The seedlings will then

Digitized by Google

have sufficient room to grow until set in the open borders. The frames should be filled with various seedlings, such as Helianthus Primrose Perfection, H. Miniature, Lavatera splendens alba, larkspurs, asters, stocks, etc.

THE HARDY FRUIT GARDEN.

Black Currants.—At this time of the year, in some seasons, birds do a great deal of damage among hardy fruits. It is wise to keep a sharp look-out and place nets over fruit plantations if birds become troublesome. I have seen stems on black currant bushes almost stripped of buds, and even at the stage when the embryo flowers were showing. DAVID ARMSTRONG

(Gardener to North More Nisbett, Esq.), *The Drum, Gilmerton, Midlothian.*

FOR GREENHOUSE AND CONSERVATORY.

Cosmos bipinnatus is very useful for the conservatory during the autumn months. For this purpose the ordinary late-flowering varieties should be used. They are easily raised from seed at this time, and the resultant plants should be grown quite cool, or else they soon become weak and spindly. As they are strong-growing, free-rooting plants, they require large pots, and should be potted on as the necessity arises until they are in 10in. pots. During the summer they should be plunged in an ash bed in an open position. Keep them carefully staked and tied to prevent damage from high winds. These plants are very useful for furnishing a supply of cut flowers.

Fuchsias for baskets are invaluable for the conservatory during the summer and autumn. Plants that were made up in baskets some time ago should have the longer shoots tied down round the baskets, and should be pinched so as to obtain well furnished specimens. Plants for flowering later in baskets should now be made up, placing five or seven plants in a basket, the number varying according to the size of the basket. Varieties that are naturally of a somewhat drooping habit are best for this purpose. Mrs. Roberts is an ideal variety, as also is the double-flowered Ballet Girl. Caledonia, one of the gracilis varieties, is excellent for baskets. Wave of Life, a variety with fine yellow foliage, is also very beautiful in fairly small baskets. It is naturally of a slender drooping habit, and also has the advantage of retaining its foliage right through the winter. Fuchsia procumbens, from New Zealand, is yet another that is good for small baskets. Fuchsias will grow and flower under somewhat shady conditions, which is a great advantage where shading has to be used for other plants. They must have a rich compost and liberal feeding if a long display is to be maintained.

Astilbe simplicifolia, which has not proved very satisfactory outdoors, is a very pretty plant for a cold, unheated greenhouse. Excellent specimens may be obtained in 48-sized pots. This plant is easily raised from seed, or where a stock exists the plants may be divided and placed in suitable sized pots. This plant grows freely in any good potting compost, and should be grown in a cold frame or greenhouse.

Saxifraga sarmentosa is ideal for filling small baskets, but it should be more generally grown in pots. Well grown plants in 48-sized pots being very charming when in flower. This plant grows freely in any good potting compost, and should be grown in a cool greenhouse during all stages of its cultivation.

Eustoma Russellianum.—Seed of this beautiful greenhouse plant should now be sown. The seed pot should be watered some hours before the fine seed is sown on the surface. Only just cover the seed with a dusting of sand; afterwards cover the pot with a piece of glass, and shade it until germination takes place. When large enough to handle the young seedlings should be pricked off into well drained pans, using a compost of medium loam, with the addition of some flaky leaf-soil or fibrous peat, and enough clean coarse sand to keep the whole open and porous. When large enough the young plants should be placed singly in small pots. The aim the first season should be to get plants with a good rosette of leaves. These plants are best grown in a low cool pit, where a temperature of 45° to 50° Fahr. can be maintained during the winter. The following spring the young plants that have come safely through the winter should be placed in 48-sized pots, in which they should flower. Really good plants may require pots 6ins. in size. J. COUTTS.

Royal Botanic Gardens, Kew.

OBITUARY

JAMES W. BENTLEY.

A GREAT figure in the floricultural world of Manchester and the North of England has passed away in the person of James W. Bentley of Stakehill, Middleton, the president of the Wakefield and North of England Tulip Society. Coming from a family steeped in floral traditions and botanical lore handed down from father to son and uncle to nephew for generations, the recreations of his busy life were associated with the old-fashioned florists' flowers, auriculas, polyanthuses, pinks, tulips and carnations.

The cultivation of the auricula claimed his youthful attention, and if his seedlings in the edged sections have not been as famous as those of his friend, Horner, many of his alpines are flowers of great merit. Among tulips he was pre-eminent as a grower, famous as an exhibitor and authoritative as to the history of the cult.

Succeeding his uncle, Samuel Barlow, in the direction of the National Auricula Society and the Royal National Tulip Society, he was indefatigable in his efforts to foster their welfare and to create and maintain interest in these flowers. Familiar as he was with their properties and their culture, his counsel was often sought and always given. In facing difficulties his courage never failed; to those who knew and loved him his kindly sympathy was hopeful and inspiring.

Thirty years ago, when May-flowering tulips were almost unknown, at the instance of Peter Barr the Southern Show of the National Tulip Society was revived under the kindly auspices of the Royal Horticultural Society, and with a view to awaken interest in the culture of the tulip a series of articles on the florists' tulips, followed by a descriptive catalogue, appeared in the Journal of Horticulture, 1894, from the pen of Bentley.

In 1897 a tulip conference was held in connection with the show of the Royal National Tulip Society and under the ægis of the Royal Botanical Society at Regent's Park, Bentley contributing a paper on the histories and properties of the tulip. On this occasion Darwin tulips were first shown. Exhibitions and lectures to botanical societies followed at York, Birmingham, Middleton, Wakefield and Manchester.

If the more austere beauties of the florists' tulip appeal only to the few who have felt its fascination and learned the properties and possibilities of the flower, the gaieties, glories and grace of the garden and the Darwin tulips appeal to everyone.

Our friend and brother—all florists are brethren—was a very busy man, a chemist and colourist, the head of a great business organisation dealing with the bleaching, dyeing and printing of fabrics—Samuel Barlow and Co., Limited—an Alderman of the Lancashire County Council and the father of the Corporation of Middleton, that metropolis of Lancashire florists and botanists of long ago.

When the war came and his sons joined the Colours, he threw himself more and more into the public service, acting as military representative of his district and, responding to the increased call of civic duties, there was less time for the recreations of his garden, but his love for and his interest in his specialities, auriculas and tulips, never flagged.

Regret is felt that further length of days was not given him, but genial and good-hearted James Bentley's memory will remain green in the affections of his friends until they, in their turn, shall respond to the call. CHARLES W. NEEDHAM.

The Midland Daffodil Society.—The annual show of the Midland Daffodil Society, which takes place at the Edgbaston Botanic Gardens, Birmingham, on Thursday and Friday, April 24th and 25th, is an event of more than passing interest to all lovers of the daffodil. The Show was founded some thirty years ago by the late Mr. Robert Sydenham, and it has been well said that it is the Mecca of the daffodil enthusiast. The beautiful varieties that are seen exhibited in London notwithstanding, it is the very cream that is to be found at the great Birmingham Show, and it is a frequent remark of visitors that they would scarcely have believed such flowers existed. An award to a new daffodil at the Midland Show is of as great value as an award by the Royal Horticultural Society, possibly greater. The winning of the Bourne Cup, the principal trophy, for new seedlings, is undoubtedly *the* blue riband of the daffodil world.

If there be in England at the moment any Colonial growers of the daffodil, it is at Birmingham on the 24th and 25th that they will find the very latest English, Scotch and Irish-raised flowers, and a visit to the Show will be well worth the making. The Midland Society still has for Secretary, Mr. Herbert Smith, of 22, Tenby Street North, Birmingham, who will welcome all visitors heartily, whether amateur growers, traders, or market growers, and will readily forward a Schedule to anyone interested. Anyone who grows anything good in daffodils should make a point of studying the Birmingham Schedule, where the classes are arranged to suit both the large and the small cultivator, and there is no Show, be it where it may, where so much kindness and attention is paid to the exhibitors when staging their flowers.

Those travelling from London will find that there are a good number of two-hour trains both from Euston and Paddington, and similar facilities when returning.

Morning trains from Euston to Birmingham are at 9.10 and 11.30 a.m., and from Paddington at 9.10 and 10.40 a.m.

Those wishing to arrive at Birmingham the evening before the Show may leave Euston at 4.35, 5.50 or 6.55 p.m., or Paddington at 4.10, 6.10 or 7.10 p.m.

The hotel accommodation at Birmingham is plentiful and varied, but the majority of daffodil enthusiasts are usually found to foregather at the comfortable Grand Hotel in Colmore Row. One should add that it is well to write for accommodation in good time.—F. H. C.

THE EDITOR'S POST BAG

WE receive letters from all over the world; in one week epistles arrived from Chile, India, New Zealand, Italy, and Vancouver, besides our ordinary post from the British Isles and the United States. Such is life, and we are interested in our communications from the world in general. It gives us—for even the Editorial Staff has imagination—a feeling of expanse; we try to imagine the conditions in which the writers of the letters live, but there are difficulties attached to our correspondence. How are we to answer an enquiry from Nairobi as to the advisability of growing English annuals in a Nairobian garden? None of us has been lucky enough to visit East Africa. One of us has travelled, but not in Africa, another lives at Kew, yet another comes from Scotland. We join forces and ponder deeply over this intricate subject; we examine floras and works of reference and find little to assist us. The result is a tactful reply to the enquirer that some annuals may grow in Nairobi, and some may not, that seed packets only cost a few pence and so may be [illegible] with an inexpensive trial, that an examination of neighbo[illegible] might help to elucidate this intricate problem. This, by the way is an interesting subject; what flowers usually grown in English gardens will succeed in East Africa, Uganda, Australia, British Guiana or any other of our Colonies? Any notes from our readers would be of interest, for Englishmen usually carry a love of gardening even as far as the back of beyond. This desire for English products is sometimes carried to excess, as in the case of a gentleman from Peking, who wished to grow English plants in his garden without having an inkling that there are thousands of plants in Korea and North China which have never been grown in gardens and which our gardeners at home covet beyond price and are unable to obtain by hook or by crook.

There is another kind of letter which is of great interest, that which asks for cultural hints. Here is one which lies before me: "I should be much obliged if you could give me any hints as to the cultivation of the following plants: Rhododendron ambiguum, Kingdon Ward 4184 (one of the Lapponicum series), Forrest 20484 (one of the Dauricum series), virgatum, Gentiana Kurroo, Gentiana angustifolia." These are all interesting plants worthy of every gardeners attention. The answer has gone forth that Rhododendron ambiguum is accommodating and likes a certain amount of sun and is satisfied with almost any soil as long as it is lime-free; that Kingdon Ward 4184 has no objection to wind, but must have perfect drainage and a sufficiency of moisture; that Forrest 20484 and virgatum are very floriferous, like perfect drainage, have no violent objection to a certain amount of sun and are ideal for planting on a scrubby hillside; that we all envy the owner of a plant of Gentiana Kurroo, which is one of the finest of gentians and likes heat, good drainage and moisture during the summer; that Gentiana angustifolia used to be included in G. acaulis, which it copies in its likes and dislikes.

Such questions are a pleasure to answer, but—and it is a big but—our difficulties really begin when a letter arrives asking for information regarding plants which will grow on a dry bank. Here are a few of the questions we could ask our correspondent in return before we can form any definite idea of what is required, and these questions do not relate to cultural conditions. Is the garden in use all the year round, or is it a summer plaything? Is the owner's idea of the bank a riot of colour, or has it the severity of a churchyard? Are the plants to sweep the ground, or are bold-shaped shrubs required? Is the entire bank to be covered? What season of the year is the owner's favourite?

We sometimes feel like giving a lecture on the art of asking questions. We are here to give advice to our readers, and yet, what answer can be given to a question of this kind? It either means that we have to write a treatise on dry-bank gardening or that we make a guess at the owner's personal idea of what is required—and nine times out of ten we shall guess wrong. Every gardener has a very good vision in his mind's eye of the effect he wishes to obtain, and it is here that the personal equation comes in. Unless full information is given in such questions we are unable to give useful advice, eager though we are to help. Our readers would really assist us, if they could place themselves in an outsider's shoes for a moment and imagine the difficulties placed in the way of giving a satisfactory answer to a defective question.

These are only samples taken at random from our post bag. They are of just as much interest to us as they are to the writers and we hope that week by week they will increase until our post bag is full to overflowing, for it helps to show that THE GARDEN is appreciated and that our advice is useful.

E. H. M. C.

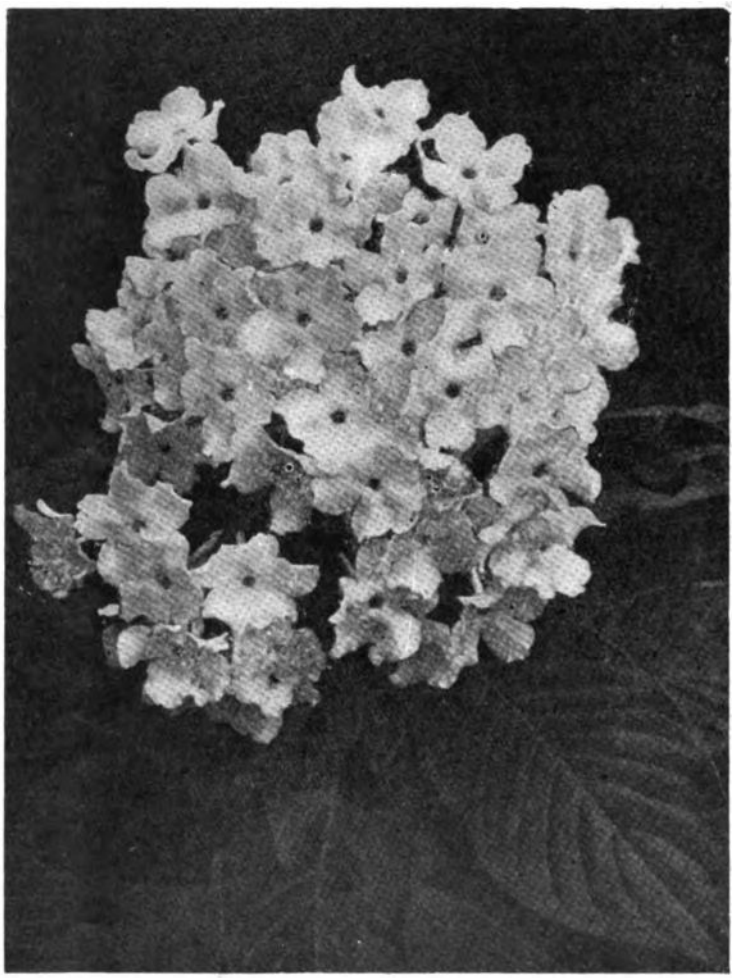
CLIMBERS AND OTHER PLANTS FOR THE CONSERVATORY AND GREENHOUSE

CLIMBING plants where they can be used without detriment to the other occupants of the conservatory and greenhouse undoubtedly add greatly to the interest, charm and general appearance of this form of gardening. Care should, however, be taken to use plants that are suitable to the size of the house, as many climbing plants are of a rampant habit and therefore quite unsuitable for small houses. On the other hand, there are a number of such plants that are quite satisfactory.

In using this class of plant one should have due regard for the other occupants of the house, choosing plants that will not unduly shade their neighbours standing underneath; in some cases the partial shade that climbers afford may be an advantage to certain classes of plants. For our purpose the term "climbing plant" is used in its broadest sense, and thus includes many plants that are not strictly speaking climbers, inasmuch as they do not support themselves by twining or by means of tendrils, but are of a suitable habit of growth to enable them to be trained to rafters, up pillars or on walls.



LUCULIA GRATISSIMA, A FRAGRANT GREENHOUSE SHRUB.

Undoubtedly the best place for growing and displaying a collection of these plants is a long corridor with a back wall, excellent examples of which may be seen at the Royal Botanic Garden, Edinburgh, and Cambridge Botanic Gardens. As a rule, such plants are seen to best advantage when they can be planted out in well drained beds or borders. In the case of some strong-growing varieties it is a distinct advantage if they can be somewhat restricted at the root. In any case it is a mistake to make the beds or borders too deep. Eighteen inches of soil is usually deep enough for most plants, not only climbers, but for other shrubby specimens that may be planted out for permanent show in large conservatories. All the plants dealt with should succeed in a cool conservatory where a minimum temperature of 50° can be maintained during the winter months.

In dealing with them in detail it will be both convenient and helpful to divide them into three sections, viz.: (1) The larger-growing and more permanent plants that are suitable for large buildings. (2) Plants of the same character but of more moderate growth, and therefore suitable for smaller houses. (3) Plants that can be raised from seed and will flower the same season.

In the first section: Acacia leprosa with its slender, graceful shoots is effective for draping pillars. A. dealbata (the silver wattle) is very beautiful but requires plenty of room. On the other hand, A. Baileyana with its lighter silvery foliage is just as charming and is not such a rampant grower. AA. Riceana and retinodes may also be used. They should be pruned hard back after flowering. Abutilons include quite a number of useful and beautiful plants for our purpose. The large broad-leaved varieties, as represented by Golden Fleece and Boule de Neige, are best grown on walls or pillars, as they are too dense when grown overhead. The slender-growing A. vexillarium and its variegated variety are ideal for draping rafters or training to wire under the roof glass. The same remark applies to the hybrid A. Milleri. The foregoing are suitable for small houses. A. insigne with its large, handsome leaves and long, slender, drooping sprays of flowers is ideal for draping rafters in a large or moderate-sized house. The large-leaved garden varieties require frequent thinning out to prevent overcrowding. The genus asparagus includes a number of fine species. A. falcatus is a rampant grower, making shoots 30ft. in length, and is particularly graceful when covered with its small white flowers.

Bougainvillæas may be used either in large or moderate-sized houses, and if they are to flower freely they should have full exposure to all the possible light and sunshine. The plants should be pruned hard back early in the year, and when they have made some growth all the weaker shoots should be drawn out. There are several varieties of B. glabra, the freest flowering being B. g. Cypheri and Sanderiana, the latter flowering freely in small pots. The most brilliant of all is the new variety Mrs. Butt, which can be flowered in 48-sized pots.

Hidalgoa Wercklei, with bright scarlet flowers resembling a single dahlia, makes growths 20ft. to 30ft. in length, and should be allowed to ramble at will or very few flowers will be produced.

Lonicera Hildebrandtiana and L. etrusca superba may be planted in large houses. The former is a giant among honeysuckles, but, unfortunately, does not flower freely. Lonicera sempervirens is very free-flowering, and is suitable for smaller greenhouses. They all enjoy free exposure to light and sunshine.

Passiflora cœrulea and its hybrids are all suitable either for large or moderate-sized houses. The white-flowered variety Constance Elliott is perhaps as fine as any and is hardy on warm walls in the south. They should be pruned back early in the year, as they flower on the current year's wood.

Tacsonias are leguminose evergreens from Australia, mostly with yellow flowers. T. Van-Volxemii is most commonly grown, but TT. manicata, insignis, mollissima and exoniensis are all worth growing. These plants should be pruned back in early spring, as they flower on the current year's wood.

Turning to the second section, we find quite a number of beautiful and useful plants for the small greenhouse or moderate-sized conservatory. Araujia sericifera (syn. Physianthus albens) is an interesting plant with white flowers, and is best planted out, but can be grown in a large pot. A. grandiflora

is probably not now in cultivation. If it is I should be pleased to hear of it.

Asparagus includes quite a number of species for our purpose. A. plumosus and its varieties are useful and popular. They may be planted out or grown in large pots. A. medeoloides (smilax) is so largely grown for decorative work that one need only mention it. A. laricinus and A. retrofractus are very distinct, and are very suitable for covering pillars, doing best when planted out in a bed of rich soil. A. Sprengeri, so largely grown for baskets, makes quite long shoots when planted out or grown in large pots.

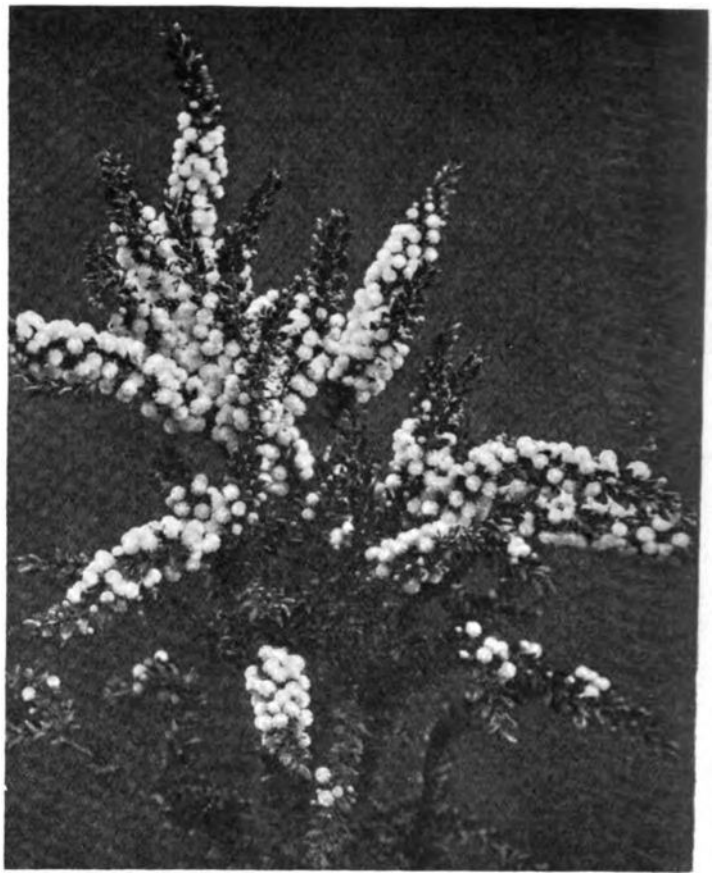
Berberidopsis corallina is very beautiful for a cool greenhouse, especially for training up a back wall that is partially shaded. This plant, if exposed to hot sunshine, is apt to suffer from attacks by red spider.

Bomareas include several distinct species, such as BB. Carderi, Caldasiana, oligantha and patacocensis. The last is a strong-growing species with beautiful crimson flowers. These plants are best planted out in a well drained bed, and they enjoy some shade during the hottest part of the day.

Cassia corymbosa is a shrubby plant which is excellent for training on a wall, and for a long time has been a favourite for this purpose. Cestrum elegans, C. aurantiacum and C. Newellii are all excellent for the same purpose or for training up pillars.

Clianthus puniceus, the parrot's bill, is also excellent for walls, pillars, or for furnishing rafters. It grows freely in any good potting compost, and can be raised from seeds or cuttings. C. Dampieri, the Glory Pea of Australia, is a very beautiful plant, but is just as difficult to grow as the other species is easy. It is raised from seed, but is very uncertain on its own roots, and is best grafted on young seedlings of Colutea arborescens. It can be successfully grown in large baskets or planted out in a well drained and raised bed in a cool greenhouse. In such a position I have seen plants make shoots 10ft. to 12ft. in length.

Fuchsias in many varieties are among the most showy and useful of climbing plants for draping rafters and pillars. If planted out in good soil they grow and flower freely for many months. Fuchsias enjoy generous treatment, and should receive frequent feeding. They also have the advantage of flowering freely in a considerable amount of shade. When they have filled their allotted space, they should be spurred hard back early in the year. They are very subject to attacks by mealy bug, which should be guarded against at all times. Any of the strong-growing varieties of fuchsias are suitable for this mode of culture.

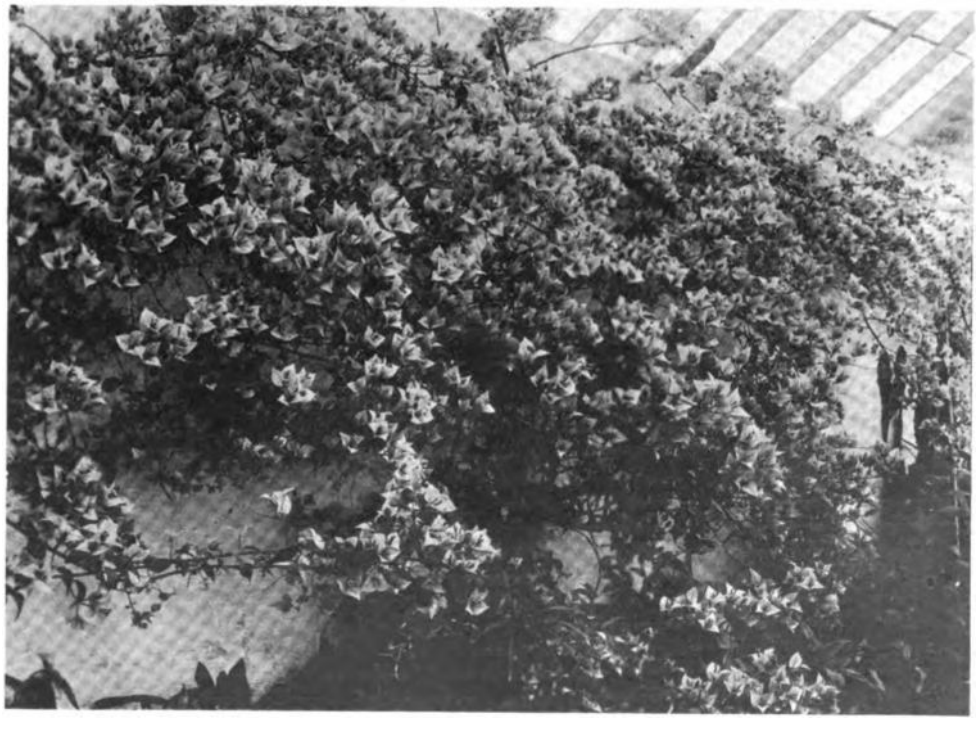


ACACIA ARMATA WITH ITS PRETTY CLUSTERS OF YELLOW FLOWERS AND LIGHT GREEN FOLIAGE.

Hibbertia dentata is a charming plant for a small greenhouse. It has dark copper-coloured leaves and bright yellow flowers, which are produced over a long period. This plant may be planted out or grown in a large pot, and it is easily propagated by means of cuttings or seed. Kennedya prostrata and K. rubicunda may be grown in pots or planted out; while Lantana salvifolia (delicatissima) is excellent for covering pillars.

Lapagerias are great favourites and enjoy a cool, moist position in semi-shade. They are best planted out in a well drained bed of loam and good fibrous peat. Lathyrus pubescens with lavender blue, sweet-scented flowers is very useful for a small house.

Mandevilla suaveolens is excellent for training up rafters. Plumbago capensis and its white variety are ideal for covering pillars, rafters or back walls; they also make fine specimens if grown in pots. Manettia inflata (bicolor) is very free-flowering and useful for small houses, and has the advantage of doing well in pots. Solanum jasminoides is ideal for an unheated house from which frost is just excluded. Clematis indivisa lobata is also very beautiful grown under the same conditions. Solanum Wendlandii is very picturesque at the warmest end of a greenhouse. It is rather a strong-growing species, and requires hard pruning early in the year. Some of the shoots will also require thinning out during the growing season. This latter remark, of course, applies more or less to all strong-growing climbers. Sollya heterophylla is very charming for training up pillars.



BOUGAINVILLÆA GLABRA MAKES A PICTURESQUE SHOW IN THE GREENHOUSE.

Digitized by Google

Coming to the third section : where houses or conditions are unsuitable for permanent climbers, quite a number of plants can be raised from seed sown early in the New Year ; these will flower during the summer and autumn. Cobæa scandens is a rampant grower and is suitable for a large house. There is a variegated variety which should be propagated by cuttings of the young shoots. Ipomœa rubro-cœrulea, Maurandia Barclayana, M. scandens and their varieties, and Mina lobata are all useful, but perhaps the most charming of them all is Rhodochiton volubile. The latter may be grown in pots the first season, or planted out in a well drained border. This plant is really at its best the second year from seed sowing. Thunbergia alata and its varieties are useful and succeed in pots. This does not by any means exhaust the list of plants that may be used for this purpose, but will serve to show that there is plenty of choice for permanent furnishing.

I will now deal briefly with some other plants, chiefly of a shrubby nature, that are useful for permanent furnishing in cold conservatories. Most of them can be grown as specimens in large pots or tubs, but it is generally an advantage if they can be planted out. Not only do they grow better, but, what is very important, they do not require so much attention as regards watering. They nearly all thrive in well-drained beds or borders filled with light or medium loam with enough clean coarse sand to keep the whole open and porous. A little peat may be necessary for some plants, but it should be used carefully, as it soon goes wrong in indoor borders. Deep borders are not necessary, 18ins. of soil usually being deep enough, with ample drainage underneath.

Camellias, especially the beautiful single varieties, are very useful ; they also succeed on back walls in semi-shade. C. reticulata, the most beautiful of them all, should always be included, especially in large houses. Some of the smaller-growing acacias are very useful, such as AA. Drummondii, hastulata, armata and cultriformis. The latter with its silvery foliage is very beautiful, cut sprays being very useful for decorative work. Orange plants in tubs or planted out are effective, but require a good deal of attention to keep them clean, as they are subject to attacks by scale and mealy bug. Luculia gratissima with its fragrant flowers should always be included, and may be grown as a bush or trained on a wall. Pentapterygium serpens is very fine, and will succeed in a semi-shaded position, and may with advantage be trained on a wall. It should have very free drainage and a compost of rough fibrous peat, loam and sand. Daphne odora (indica) should always find a place, being well suited for the front line. Pimelia ferruginea is well suited for a small house, while P. ligustrina is better suited for large borders. Chorizemas are seen at their best when planted out, some of the strong-growing forms of C. cordatum being useful for training on walls or pillars. All the greenhouse rhododendrons do well either in tubs or planted out. Some of them of a somewhat straggling habit, such as R. fragrantissima and R. Forsteriana, may with advantage be trained on walls.

Tibouchina semidecandra is also excellent for a sunny wall, as also is Browallia Jamesoni. This plant should be exposed to all the sunshine possible. Desfontainia spinosa and Crinodendron lanceolata are very useful for a house from which frost can be excluded. Clivias, either in tubs or planted out, add to the variety, while Strelitzia Reginæ with its handsome foliage and extraordinary-looking flowers should always find a place.

For foliage effect Roupala Pohlii is necessary, whether grown in pots or planted out, as also is Bucklandia populnea. Where a quick-growing plant is required, Impatiens Oliveri soon makes a huge specimen and flowers all the year round. Callistemons, eriostemons, Mitraria coccinea and Lomatia ferruginea may be planted out. There are, of course, many other plants which could be mentioned. There are numerous ferns and other small-growing plants that may be used to carpet and edge the beds. Such beds provide just the right conditions for the successful cultivation of Lilium sulphureum. Many other bulbous plants that are not over happy in pots will do well when planted out.

J. COUTTS.

THE NEW PANSIES

ALTHOUGH there are not quite so many new pansies as violas, it is possible that the 1924 novelties will prove to be the best set that has been sent out for many years. Some of them are of outstanding merit. Mrs. Andrew Frater is a wonderful new colour, the Cochrane and Beveridge varieties are of first-rate quality, and Mr. James Paul is allowing some of his famous seedlings to pass into commerce. I have had the privilege of trying many of Mr. Paul's latest introductions during the past two years, and I can confidently recommend Mary Drummond, Dr. McKinnon and Jessie McLaughlin as being worthy of a place in any up-to-date collection. The names in parentheses indicate the raisers and introducers.

ADA M'COWAN (Cochrane–Douglas).—Dense dark plum blotches with margins of rose and lemon. The top petals are lemon, mauve and rosy purple with plum pencillings and a wire edge of white. A splendid flower.

ALEXANDER TAYLOR (Stevenson).—Dark plum blotches with margins of pale chrome yellow. The top petals are dark violet streaked with yellow and violet and edged with pale chrome. It is a seedling from Tom M'Callum. Mr. Andrew Stevenson sent me an advance trial of this variety last season, and I found it very reliable and distinct. It is a good grower and has a nice habit.

ANDREW MELDRUM (Beveridge—Penman).—Deep amethyst blotches with margins of cream and heliotrope. The top petals are cream suffused with amethyst and heliotrope. It has a fine smooth texture and is of splendid form.

ANNIE BEVERIDGE (Beveridge—Penman).—Deep violet-black blotches margined with terra-cotta shading to lemon. The top petals are lemon shaded with terra-cotta. A large flower of fine form.

DAVID STEWART (Beveridge—Penman).—Reddish purple blotches with margins of terra-cotta and cream. The top petals are cream marked with terra-cotta and purple. This lovely coloured flower has size, good texture and fine form.

CORRIEDALE (Paul—Douglas).—Dark purple blotches with margins of old rose and white. The top petals are light purple shading out to white. It is a very large flower of fine texture and perfect form.

DR. MCKINNON (Paul—Douglas).—This is the largest pansy I have grown. It is a well proportioned flower and the habit of the plant is good. The large blotches are plum coloured with margins of lemon. The top petals are lemon with splashes of rosy purple, and they are edged and suffused with light purple.

DRYDEN MACCOLL (MacColl — Douglas).—Dark plum blotches with margins of purple lake and gold. The top petals are pale gold with a deep edge of purple lake and a wire edge of gold. This is a large flower of very beautiful colourings.

JAMES CLIMIE (Stevenson).—Chocolate blotches with margins of yellow and crimson edged with white. The top petals are pencilled with chocolate with a band of yellow and crimson. It is a seedling from George Stevenson. A flower of wonderful colourings.

JAMES COWAN (Stevenson).—Deep violet blotches with light violet margins and a band of amethyst at the outer edge. The top petals are cream with a suffusion of amethyst. It is a flower of fine form with a grand under petal.

JESSIE MCLAUGHLIN (Paul—Douglas).—Deep brownish purple blotches with lemon margins. The top petals are lemon and crimson with splashes of purple. I have found it a very reliable variety, of good habit and pleasing colour.

JOHN PENMAN (Penman).—Amethyst blotches with margins of heliotrope and creamy white. The top petals are creamy white splashed with amethyst, with a wire edge of the latter shade all round the flower. It has a smooth velvety finish and is a flower of the largest size and fine form.

MARGARET ALEXANDER (McAlpine).—The blotches are Prussian blue with margins of white and rose. The top petals are white with Prussian blue pencillings and suffusions and an edge of rose. Unique and pretty colourings.

MARGARET BISHOP (Cochrane—Douglas).—Deep plum-purple blotches with margins of cream. The top petals are cream with purple suffusions and

Digitized by Google

pencillings and a wire edge of cream. It is a splendid flower of large size, good form and fine texture.

MARY DRUMMOND (Paul—Douglas).—This is probably the best variety of its colour. Dark brown blotches with margins of deep yellow suffused with crimson. The top petals are deep yellow with an edge of crimson. It is one of the prettiest pansies that I have ever grown. The flowers are of great size, splendid texture and good form.

MRS. A. HARRISON (Harrison and Sons).—I saw blooms of this last season, and it promises to be the best of its class. It has dark violet blotches with cream margins and a suffusion of violet on the top petals. Virtually a cream self.

MRS. ANDREW FRATER (Frater—Forrest).—This new colour break is regarded by many as one of the great pansies of the year. It has deep plum-purple blotches with a ring of sulphur yellow that shades to old rose and magenta. The top petals are pencilled with the same rich colourings. It is a very beautiful flower of fine form and texture.

MRS. H. ANDERSON (Anderson—Penman).—Deep violet blotches with cream margins. The top petals are cream with streaks of violet. It is a large, smooth round flower of the highest quality.

MRS. JOHN FERNIE (Robertson—Penman).—Deep purple blotches with terra-cotta margins and a cream edge. The top petals are terra-cotta with purple splashes and an edging of cream. A richly coloured flower of fine form.

MRS. ROBERT MACFARLANE (Douglas).—A very fine flower of the Mrs. A. McAlpine type and one of the largest varieties in cultivation. The deep plum-purple blotches are margined with rich cream and the top petals are violet-purple with darker pencillings and a wire edge of cream. Very free-flowering.

MRS. WILLIAM TENNANT (Tennant—Forrest).—Dark plum-purple blotches shading to rich crimson with an edge of cream. The top petals are violet, purple and cream. It is a seedling from the popular variety Alex. Lister.

MISS WHITELAW (Forrest).—Dark plum purple blotches with cream margins. The top petals are plum purple mixed with cream. It is a large flower of fine texture.

ROBERT BEVERIDGE (Beveridge—Penman).—This will probably prove to be one of the sensational introductions of the year. It has deep purple blotches with magenta margins shading to white. The top petals are white streaked with purple and edged with magenta. Bright and unique colourings.

SAM HANNAH (Beveridge—Penman).—Deep maroon blotches with margins of pale yellow and red. The top petals are pale yellow marked with maroon and red. A flower of very brilliant colour and smooth texture.

SUSAN STEVENSON (Stevenson).—Dark blotches with margins of yellow and crimson. The top petals are pale gamboge with a band of crimson. Another very beautifully coloured variety and one that can be grown to the largest size.

In addition to the above 1924 introductions there are many fine varieties that were sent out in 1923, notably T. B. Cochrane (probably the best white self in commerce), Mrs. A. B. Cochrane (one of the best pansies yet introduced and very floriferous), Dr. Kelso (very fine in autumn), Jean Lister M'Kellar (almost a creamy white Alex. Lister), J. B. Macdonald, Robert Cochrane, Agnes Cochrane, Sunset, James Ballantyne and John Craig.

Older varieties that are indispensable for exhibition purposes include Andrew Stewart (which should be shaded for the best results), Nellie Cochrane (which is very fine in a wet season), Dr. Ogilvie, John Greig and Councillor Steel. Alex. Lister is an old favourite, very reliable, and invariably wins the prize for the best bloom in the show. NORMAN LAMBERT.

WIND-BREAKS

BY SIR HERBERT MAXWELL, BART.

WIND-BREAKS may be required for one of two purposes: (1) To afford shelter to a considerable extent of ground, be it open park or woodland; and (2) to protect flowering shrubs or garden borders from searching winds.

(1) Taking the larger proposition first, this should be effected by planting such forest trees as can rear themselves to a respectable height in extreme exposure. It was at Gosford, on the coast of East Lothian, if I mistake not, that a candidate for the vacant situation of forester, after inspecting the woods, declared that he could not undertake charge of them unless the existing staff was considerably increased. Being asked the reason for his refusal, he explained that the enormous amount of clipping to be done would require a great number of hands. This man's experience had been acquired inland, and he attributed to manual labour what really had been done by the sea blasts, smoothly shaving the shelter belts to a uniform slope.

The conditions affecting inland districts are very different from those near the coast, for not only are winds more constant and, usually, more violent in the latter, but they are also heavily charged with brine, which destroys young foliage. Still, there are many bleak and exposed tracts far from the sea in Great Britain, and judgment must be exercised in choice of

THE CORSICAN PINE (P. LARICIO) IS EXCELLENT FOR AFFORDING SHELTER.

Digitized by Google

species for a shelter belt. There is no tree so well adapted for such a situation as the Corsican pine—P. Laricio—which grows erect in full exposure and has the merit of being rejected by rabbits. The Austrian pine, which some botanists reckon to be but a variety of the Coriscan, is equally fearless of wind, but is far inferior in habit and appearance; moreover, rabbits greedily devour it. If the windward side of a shelter belt is planted four or five deep with Corsican pine, the leeward portion may be filled with other conifers, or hardwoods such as oak, beech and sycamore.

The choice of species suitable for protection against wind directly off the sea is much greater than that for inland places. Here again reliance must be placed upon conifers for the windward side of a shelter belt. The Corsican pine may be used with confidence; but Pinus radiata (insignis), the Sitka spruce (Picea sitchensis), the Monterey cypress (C. macrocarpa) and the pinaster (Pinus Pinaster), being native to maritime districts, are specially well adapted for the purpose. Except the Sitka spruce, these species will not survive a hard winter far from the sea. The pinaster has the peculiar habit of thrusting out its strongest limbs in the teeth of the prevailing wind. The Landes of Gascony, extending for 100 miles between Bordeaux and Bayonne, were formerly a barren, windswept region, absolutely worthless for agriculture or any other purpose. They are now clothed with pinaster, "perhaps," as the late Mr. Elwes observed, "the most extensive forest ever created by the hand of man." Thirty years ago the planted area amounted to 1,715,000 acres, and in 1904 the average revenue derived from the sale of pit wood, resin and turpentine was reckoned at £560,000, or 7s. an acre. Shelter belts must always be liable to loss in exceptional gales, wherefore it is a wise precaution to underplant with beech, which will take the place of such trees as may be blown out. It is also good policy, especially where blown sand has to be dealt with, to line the outer edge of the plantation with sea buckthorn, which soon forms a dense hedge for the protection of the young trees.

(2) Turning now to consider wind-breaks for garden and pleasure ground, one is met with the same paucity of material for inland places compared with the abundance of species available for maritime districts. For the former, there is no more effective shelter-plant than the prostrate, or semi-prostrate, forms of Pinus montana. The varieties named Pumilio and Mughus are of spreading habit, forming in time a dense mass about 6ft. high which no wind prevails to disturb. It is a pity that its virtue is not more generally recognised, for it would prove of inestimable value if planted for the protection of windswept villa gardens in watering-places. Care should be taken to ensure obtaining the low-growing variety. I was supplied once with the variety uncinata, which attains a height of 80ft., and did not discover the mistake till several years later.

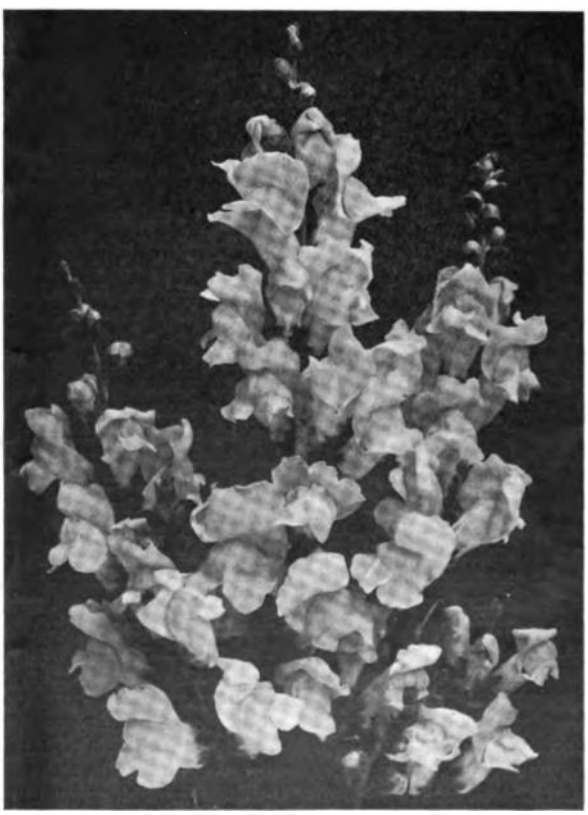
In maritime districts the Monterey cypress is invaluable for garden shelter, forming splendid hedges of lively green and standing clipping into any form. The hedge should be grown broad at the base with a good slope to a narrow top, else it is apt to get bare below. For this purpose, propagation may be rapidly effected by cuttings, which strike readily and grow very fast. Equally effective as a shelter from sea wind, but not of such rapid growth, is Grislinea littoralis from New Zealand. This also is easily raised from cuttings. Add to the aforesaid species, sea buckthorn (Hippophæ rhamnoides), taking pains to plant both sexes so as to ensure plenty of orange berries, and the tale of shelter plants against *extreme* exposure to wind from the sea is about complete; but there are plenty of others which flourish when encouraged by very slight protection, such as Olearias macrodonta and nitida, Leptospermum, Fuchsia Riccartoni and globosa. I had well-nigh forgotten to mention the holm oak (Quercus Ilex), which is an admirable forest tree in places near the coast. At Castle Kennedy it has been cut into a most substantial hedge for the protection of rhododendrons.

THE CULTURE OF ANTIRRHINUMS

THE days are not very far distant when the antirrhinum was raised entirely by cuttings. Although this method is still carried out with very special plants and in working up stocks of new varieties, the most popular and easiest method now is to raise from seed.

It was not until about 1913 that the antirrhinum was taken up by the seedsmen and cultivated intensively, with the result that they will now breed fairly true from seed. Although the number of varieties almost rivals the sweet pea, we are greatly assisted by the foliage, which, with few exceptions, varies in each variety, thus enabling those of different colouring to be detected when pricking off, and reducing the variations in the flowering season to a minimum.

The value of the antirrhinum as a bedding plant has attained a very high standard. We have only to go into our public parks and see the gorgeous displays in beds to verify this. Wonderful effects are attained by massing these handsome flowers. It has always been a wonder to me that it has not been taken up more as a florists' flower. There are some wonderful shades of colour afforded, and the handsome spikes in the tall varieties should make them esteemed by all florists. In America they are cultivated under glass for this purpose and always meet a ready demand.



HANDSOME SPIKES OF ONE OF THE MANY VARIETIES.

Antirrhinums are classified according to their height, viz., tall, intermediate and Tom Thumb. Although they will be found to differ slightly on various soils, the tall section usually attain a height of 2½ft. to 3ft., the intermediate 1½ft. to 2ft., and the Tom Thumb very rarely reach over 1ft.

Undoubtedly the intermediates are the most popular, because of the wide range of colour afforded and their value as bedding plants; but the tall varieties are the florists' and the exhibitors' flower; they produce the finest spikes, often with as many as three dozen blossoms, and the finest individual blooms. The Tom Thumbs are used largely for edging.

The antirrhinum can be raised as an annual or a biennial. Treated as an annual the seed should be sown in January or February, in boxes or pans, in a heated greenhouse, the seed being sown in soil containing a large percentage of sand, which should be watered before the seed is sown. As the seed is so very minute it is not necessary to give much covering—in fact, often they are sown with no covering at all. Place glass over them until germination takes place. Care must be exercised when watering; a very fine rose should be used and the water distributed evenly, otherwise an irregular germination will take place. When the plants are large enough to

Digitized by Google

handle, prick off into boxes and allow them to remain in the house for a week, gradually hardening off by placing in a cold frame. By the end of April they should be ready for planting in their flowering quarters. A sunny position should be found for them, if possible, as they do not thrive in shaded places or in soil that is in any way damp. It is advisable with all varieties in the intermediate section to pinch the centre right out; this causes the plant to break and become sturdy and bushy. It is not an important factor to the amateur, but to the seedsman the antirrhinum presents no small difficulty in keeping each variety true to type and colour. The large bees work these flowers, constantly carrying pollen from one blossom to another, and unless each variety is strictly isolated the seed saved will produce a hopeless mixture; but even with the strictest isolation a certain percentage of variations will be found; still, as previously mentioned, these can, to a great extent, be detected when pricking off.

ANTIRRHINUMS, WHEN MASSED, FORM A PRETTY BORDER OF MANY COLOURS.

The best specimen plants are obtained by treating as a biennial. Sow the seed in August in a similar manner as when raising as an annual. When pricking off, it is advisable to do so into a frame which has had old manure incorporated with the soil. Here they are afforded much more room in which to make roots during the long period they are to remain than they would have were they pricked off into boxes. Immediately they are pricked off they should be shaded, or the sun will scorch the seedlings before they get properly rooted. They should be gradually hardened off until the sashes can be left off altogether during the winter months; by March they should be strong and sturdy plants ready for planting out.

In many districts it will be found that they will stand the winter outside quite well, and if this method is to be carried out the seed must be sown in June and the plants transplanted to their flowering quarters by the early autumn. Like sweet peas, it would prove very difficult to select varieties for everyone's taste, but the following are really first-rate:

Picture, a new variety this year, will only have to be grown once to make it a favourite. It has a golden yellow ground with lips and falls suffused apricot, and the standard bright apricot.

Eclipse, another new variety this year, is a very brilliant crimson, of ideal habit and very sturdy.

Prima Donna is a popular variety, as it comes very true from seed with hardly a variation. It is a lovely shade of apricot, with a white tube.

Other good varieties are Afterglow, Fascination, Maize Queen, White Queen, Amber Queen, and Roseum superbum, the latter being preferred to Nelrose.

The tall section does not offer such a wide selection, but the following can be relied upon: Yellow King, Queen Victoria, Crimson King and Moonlight.

The Tom Thumbs are generally known by their colours, of which T.T. Yellow, T.T. Crimson and T.T. White are the best.

G. IRELAND.

(Further articles on the Antirrhinum to follow.)

THE GOOSEBERRY MILDEW

THE term mildew is in many cases somewhat of a misnomer in that it has come within the last few years to be applied loosely. Any discoloration, generally whitish in appearance, such as may often be found on various domestic belongings and plants—boots, potatoes, roses, etc.—is referred to as a mildew. To the botanist or mycologist, however, the mildews form a distinct family of fungi entirely apart from their neighbours and are to be found under the name of Erysiphaceæ in the group of the Ascomycetes characterised by the production of an ascus and ascospores, which are analogous to the seeds of the higher flowering plants. The Erysiphaceæ is a large family embracing quite a number of genera and species which are to be found on many host plants. The family is said to be strictly parasitic, but the relationship between the parasite and the host is an interesting one, approaching in some cases, a condition of mutual benefit. The fungi are characterised by the possession of thin-walled strands which are interwoven to form a mass of cobweb-like mycelium which is greyish-white in appearance. This spreads over the surface of leaves, shoots, flowers, and in many cases, fruits. From these strands there are sent out small peg-like outgrowths, known as "haustoria" which are adpressed to the surface of the leaf. The epidermis of the leaf is ruptured and the fungus gains entrance to the tissues of the host. In many cases, the host appears to live happily for a long time after infection, but gradually a weakening occurs till, finally, death may ensue unless prompt remedial measures are taken to counteract the disease.

The American Gooseberry mildew (Spærotheca mors-uvæ) belongs to this family, and is a fungus which has been causing most extensive and serious damage to gooseberry bushes throughout the whole country. In many instances, the culture of the gooseberry has been rendered well-nigh impossible owing to its ravages, and it is to be hoped that some efficient remedial method and treatment will be evolved whereby it may be kept in check if not eradicated from our midst.

There are two stages in the life history of this fungus which correspond more or less to the season of the year. Let us commence with a gooseberry bush which has been infested by spores in spring. These germinate, and a whitish mycelium is the result, which spreads rapidly over the surface of the young leaves, stem and, later on, to the fruit. During this vegetative growth of the fungus, rapid reproduction is carried on throughout the summer by means of small oval-shaped spores known as conidia. These are borne in long chains at the end of the thread-like branches. Their number is enormous, but to a certain extent this is counteracted by the fact that they are short-lived, although they germinate rapidly under suitable conditions, such as moist and warm weather. The host plant now appears in mid-summer covered with a mealy or chalky powder, which is characteristic of the disease. This is the summer stage and occurs from May to about the end of October. The foliage, and fruit where infected, are greatly damaged. The leaves curl up and gradually assume a withered look, losing their green colour. The attacked fruits shrivel up and remain with a hard outer whitish skin till they gradually drop off and fall to the ground. Towards the end of the summer and during the autumn the whitish colour gives way to a brownish velvet covering the foliage and stem. As time goes on and if a careful examination be made, minute blackish spots will be

Digitized by Google

seen occurring all over the surface of the host embedded in the brownish felt. These are the small globular winter fruits (perithecia) of the fungus. These bodies are brittle and thick-walled and able to resist a great deal in the matter of extremes of temperature. It is these bodies which tide the fungus over the winter months. The fruits fall from the bush in late autumn and lie dormant in the soil till the following spring or summer when the wall breaks, the asci, each containing eight spores being shot out, each spore capable of infection if conditions are suitable. By some it is held that these fruits may sometimes lie dormant over a whole year and infect a bush in the second year. It will thus be recognised how difficult it is to deal with a disease of this nature which has two entirely different modes of spread. Lately, some are also of the opinion that the fungus can exist through the winter in the form of a resting or dormant mycelium which is capable of springing into being through the stimulus of the warm spring days and giving rise to the summer spores. If such is the case, it is of enormous importance, as this mycelium would also have to be killed as well as the winter fruits.

The mildew attacks the young rapidly growing and vigorous shoots of the gooseberry bushes in moist and warm weather. Fortunately, the spread is not too rapid. Young sucker shoots arising in spring are more liable to be attacked than the older slow-growing ones. Thus, quick-growing varieties of gooseberry are more susceptible, especially when growing in highly manured ground. Apart from the question of vigorous growth, the varieties appear to have no special resistant powers. In districts where the soil is deep and porous, containing an abundance of moisture the disease is apt to spread rapidly, and this may to some extent account for the unequal distribution of the attack in areas where differences in the soil occur.

All growers of gooseberries should take the necessary precautions if they find the disease on their bushes. Infection may be the result of various agencies, such as wind, birds, insect and even man. The former, no doubt, do not come under the grower's control but he should do all in his power to lessen the chances of spread. When prompt action is taken after the mildew has been noticed, the chances of spread are limited to a large extent. If the attack be neglected, then the costs of prevention and cure are not worth the trouble. The bushes should be sprayed with a lime-sulphur mixture, and then grubbed up and carefully burned as well as the surface of the soil where the bushes existed. When the fruit is badly attacked this is the method to be employed. When working in an infected plantation, the clothes should be changed before proceeding into an uninfected part, as the spores will adhere to the garments and will be rubbed off when in contact with the clean bushes. This is an important point to be attended to, as cases of infection can often be directly traced to this neglect.

Care should be taken when buying new bushes to see that they are perfectly healthy. After planting, inspection should be carried out at intervals during the summer, and the bushes, if they seem infected, such as the whitish appearance on the under surface of the leaves, should be sprayed with liver of sulphur, or better still, lime sulphur, to prevent a rapid spread. Lime sulphur wash is very effective indeed, and the treatment lasts much longer than is the case with liver of sulphur. This wash should be applied with caution, as, unfortunately, if it is applied in too strong a concentration and too often it causes the leaves to drop off, and the bushes assume a withered appearance. The bushes should not be sprayed while in flower, but when the young fruits appear a light spraying is beneficial, as the disease generally attacks young fruits. If there is no fruit on the bushes Bordeaux mixture may be applied. A useful hint when making up these washes is to add soft soap, about 4lbs. to every 40 gallons of water. This ensures a thorough wetting of the bushes in that the spray will adhere to the foliage and stems. When the disease is prevalent, pruning of the bushes, after all growth has ceased, should be resorted to. The bushes should first be sprayed, then pruned and the prunings burned on the spot. The prunings must not be carried all over the plantation, as it is in this way that the spores are distributed. All twigs exhibiting the summer stage are highly infectious and should be removed immediately, also those showing the winter stage. These winter fruits often appear and drop off as early as August, so it is well to take preventive measures early in the summer. Slow-growing varieties are preferable, and nitrogenous manures should be applied sparingly as these encourage soft, rapid stem growth.

This mildew is found on many other host plants, including the wild gooseberry and if this occurs in the vicinity of the garden inspection should be made, and if infected it should be grubbed up and burned. If it is allowed to remain it will prove a source of infection to the cultivated bushes. Many weeds also act as carriers of infection, so that it is well to keep the surroundings of the bushes clean and tidy so as to give them every chance. This species of mildew now also appears to be attacking the currant, that is, it seems to be changing its host, but whether the damage to the currant will prove as serious as it is to the gooseberry remains to be seen. It is well, however, that the currants be grown apart from the gooseberries to avoid the possible contamination. G. C. T.

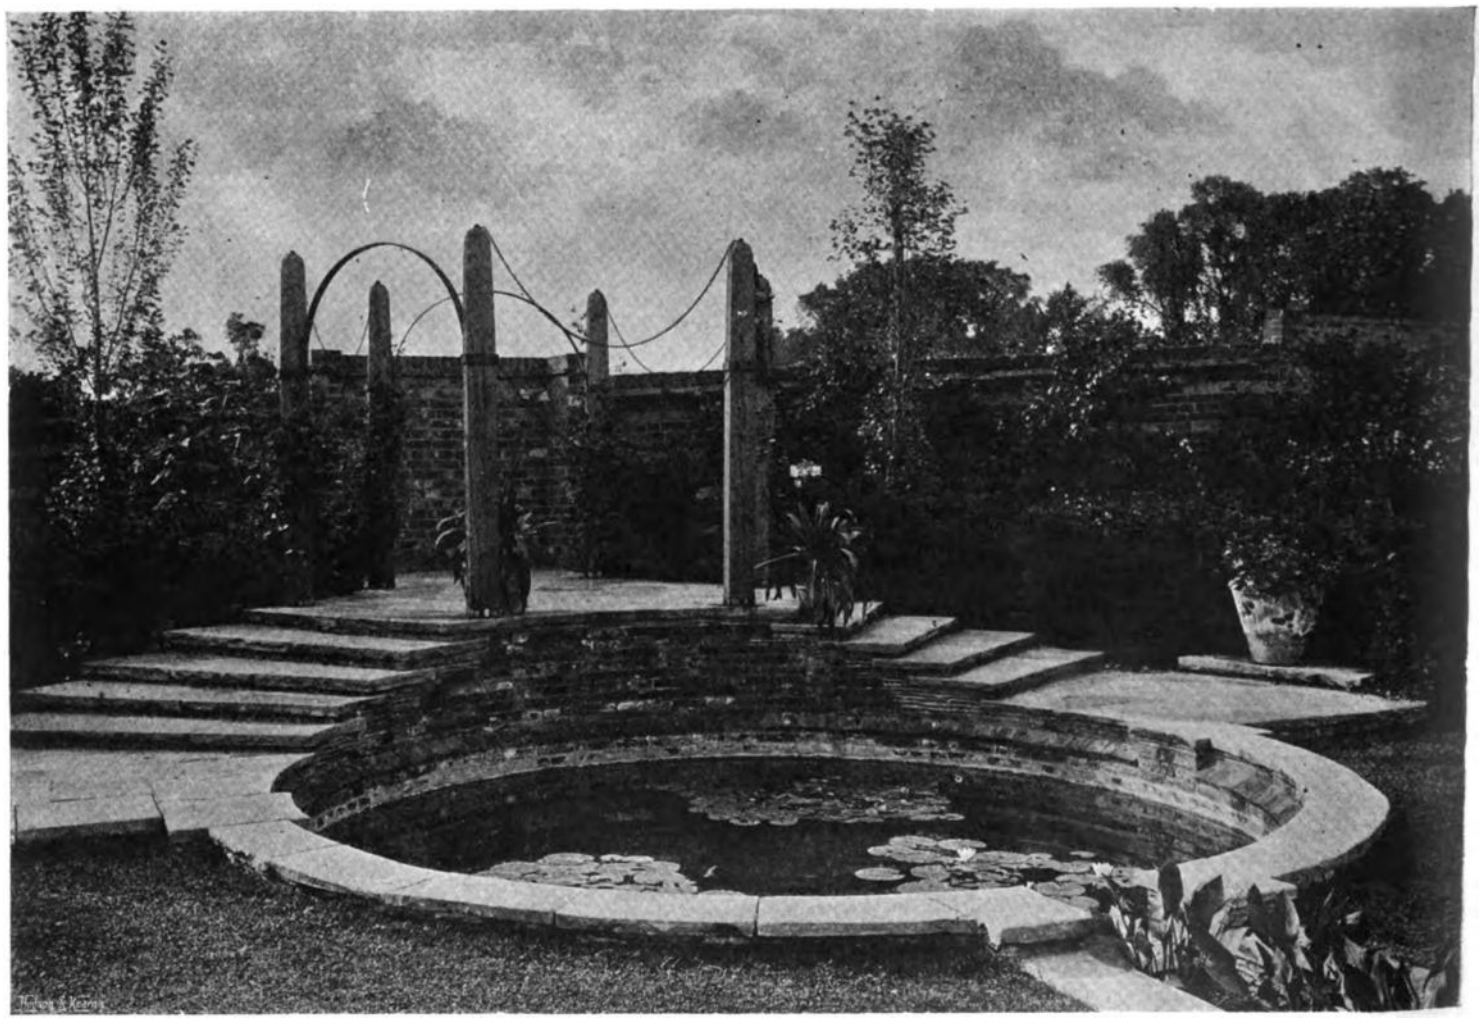
SOME GARDEN ORNAMENTS and ACCESSORIES

BY GERTRUDE JEKYLL.

FOR the best examples of outdoor ornament we must look to the old gardens of Italy. They may well have been the prototypes of all later decoration of the kind, for they were designed and carried out by the greatest living architects and sculptors of the time. Only a few of these gardens remain intact, many have passed into the hands of impoverished owners who have been glad to sell anything that could be removed, while some have gone into complete neglect and ruin, and others have been entirely destroyed. Stray items—urns, vases, carved seats and fountains—have come into the hands of dealers and have been widely dispersed.



LILY TANK WITH A CHARMING SETTING IN A GARDEN AT SONNING.

Vases, tazzas and urns originally stood as accentuating ornaments on the piers at the tops and bases of flights of steps, and on those that occurred at intervals in ranges of stone or marble balustrades. These vases were for the most part also of stone or marble, but some were of terra-cotta with a good deal of ancient classical feeling in the ornament. Such a vase is the one illustrated. The design is something of a compromise between that of sculpture and the terra-cotta tradition, for the form and detail of ornament belong to the terra-cotta, but the handles are unusual in this medium. It is impossible to say whence this vase, and many such examples that one meets with here and there in gardens, may have strayed from; the only thing evident is that it looks lost and out of place without anything definite to stand on, though in the vase shown this is less of a necessity than if the form and ornament had been more of the vase or tazza character. Tulips are but a weak kind of filling; the important aspect of garden vases demands something stouter or more woody. Two year old pelargoniums or well furnished fuchsias are among the best plants for vases, the pelargoniums especially, for they thoroughly enjoy the sun warmth that penetrates the whole body of vase and earth.

Sundials and other solid ornaments are often misplaced. In the old gardens for which they were designed they were always given a definite position, either in the centre or at the end of some distinct garden scheme, and they stood on some kind of base, generally of one or two wide steps. A large vase or urn on an imposing plinth would be placed at the end of a vista, sometimes, and always with good effect, in a niche of dark greenery. In modern gardens it is not unusual to find these ornaments placed in or about a lawn for no apparent reason and, worst of all, without any base and therefore looking, as they needs must, as if they had lost their way and felt forlorn. It is almost better to have no ornament than to have a good ornament badly placed. Another common defect is when one sees a number of vases, or whatever it may be, of different kinds and sizes scattered about a garden. These objects belong to formal design and well considered proportion, right and perfect in their original places, but not at all easy to use properly in a different environment. Such a mixture gives the same uneasy impression as is received on entering a room furnished with a Louis-Quatorze escritoire, an old English farmhouse linen hutch, an eighteenth century card table, and chairs of any period from Cromwell to Queen Victoria. Each piece may be genuine and good of its kind, but there can only be

Digitized by Google

a sense of painfully clashing incongruity when they are brought together.

The same general considerations are applicable to garden seats. A great house of palatial character will probably have architectural features in any part of the garden that is near the main building. Here there will be wrought stone seats with sculptured detail as to supports and bench ends. A balustraded terrace in an upper level may have projecting bastions; places between these will be found for specially designed stone seats, and others will come at the ends of terraces and at other distinct points, as on the landings of wide stairways. An eighteenth century manor or dower house will be well suited with such a wooden seat as is shown in the illustration, or with one of the seats of French design of the same period that are still made and can be imported. For ordinary houses there are garden seats of good simple design made of hardwoods from old wooden ships. When a painted seat is used it is best to avoid the very harsh white that is so commonly employed, for it often happens that the glaring white of the seat attracts undue attention. It is easy to modify the colour so that it tells as white, if white is desired, and yet is not obtrusive. Plain oak weathers to a beautiful colour, a kind of silvery grey, if untouched. The maker will probably want to oil or varnish it, but this should be firmly resisted. It is delightful to have seats at many points in any region of home woodland that comes near the garden. Here they should be of the very simplest form, merely planks nailed to four stout stumps that are let into the ground. If a back rest is required, the back stumps should be chosen from a branching tree, the branch, which is to support the back rail only slightly diverging from the line of the trunk if it is to give suitable support, for nothing is less comfortable than a hard wooden seat that throws the sitter too far back. Seats are often fixed in summer-houses, but seldom with the care for detail as to height and width and slope of back that makes for simple comfort. If one may go by the evidence of illuminated manuscripts of the Middle Ages, it would appear that our far back ancestors were content to sit on grass banks, for so they are represented in the curious "Romanst of the Rose," which contains some of the earliest known illustrations of pleasure gardens.

Where a garden has the advantage of water in small or moderate volume there is no better way of employing it than in the narrow rill with little tanks at intervals. The width is not more than 15ins. to 18ins., so that it is easily stepped over. The sides of the rill, which passes through any space of lawn, are built in stone or brick with a flagstone top level with the grass. The water is shallow for the accommodation of such plants as the beautiful natives, the water plantain (alisma) and the flowering rush (butomus), which grow by river banks in water only a few inches deep. This kind of built and planted rill was first designed by Sir Edwin Lutyens for the garden at Sonning: the end tank and steps are seen in the illustration on opposite page. The tanks are built deeper than the rill to admit of the planting of water lilies. The steps that lead to the higher level have a very slight rise of about 4½ins. and are wide in the tread. Steps of such proportions are not only pleasant to walk, or even run up and down, but are also agreeable to the eye and mind, suggesting ease and slight effort. Where there are steeper slopes there may still be easy steps, for where it is too steep for them to go conveniently up and down a landing can be built straight forward and the steps be taken down to right or left or both, with a second landing and another square turn of the steps. The example shown is on the same principle, though the slighter difference of level does not need the second landing, and the form is circular, following the curve of the tank. The end of the planted rill shows in the foreground. In the case of some tanks that might be dangerous to children, a space about 2ft. wide can be built up inside. The space is filled with earth to the level of the inner wall for aquatic plants. Another way which is always beautiful is to build the whole tank in wide under-water steps, the successive depths showing in an interesting way by the deepening colour of the water.

THE SPRING ROSE SHOW

NO doubt on account of the bleak, wintry conditions, the Spring Show of the National Rose Society did not attract such a large attendance at the Royal Horticultural Society's Hall, Westminster, on April 11th, as on some former occasions. However, the hall was comfortably filled throughout the afternoon and until closing time there was quite a crowd around the table containing the new roses.

THE MAGNIFICENT LARGE, WELL-FORMED PINK BLOOMS OF ROSE AMERICA.

Such a late spring as we have experienced this year has been very unfavourable, so that the exceptionally high quality of the blooms came somewhat as a pleasant surprise. Among the many exhibits it was a difficult matter to find half a dozen poor blooms and curiously enough the only really weak class was that for six blooms of new roses first put into commerce since the beginning of last year. Mr. E. J. Hicks was the only exhibitor and although he was awarded the first prize, the blooms, though quite fresh, were a poor lot. It would seem that the more recent novelties are of no value for forcing purposes. Yet, apart from these, there was a great variety on show, and of first-rate quality.

Decidedly the best blooms in the show were grown by amateurs and it would be difficult to imagine any finer forced roses than the specimens of Mrs. Foley Hobbs, Louise Crette, Muriel Dickson and Richmond, as shown by Mr. G. A. Hammond in his first prize board of twelve blooms of exhibition roses, for they were superb. Mr. E. J. Holland, who had to be content with the second prize also staged most admirable blooms, particularly of Caroline Testout, William Shear, Mrs. J. H. Welch and Hadley. The group of cut roses so well set up by Mr. Hammond was also of exceptional merit. He included a lovely basket of mixed sorts and vases of Mrs. Henry Morse and Frau Karl Druschki.

The circular groups of pot roses made a delightful display. With magnificent blooms of Mrs. Foley Hobbs, Mr. J. A. Hammond won the first prize for six of any variety, while Mr. L. P. Roberts, showing Augustus Hartmann, Dean Hole and Yvonne Vacherot of good quality, was first in the class for growers of fewer than thirty plants of pot roses.

The circular group of pot roses in the nurserymen's classes made a delightful display, and for elegance and graceful bloom the first prize exhibit of Messrs. A. J. and C. Allen has rarely been surpassed. Their tall plants of Dorothy Perkins, Blush Rambler and White Dorothy Perkins were especially charming, while the conventional standards of Hadley, Lady Hillingdon and Golden Ophelia were also profusely flowered. Among the dwarf pot plants which formed the ground work to the group, there were many brilliant little plants of the geranium-scarlet La Reine Elizabeth, a most vividly coloured little rose. In the second prize group of Messrs. Chaplin Bros. there were plants of Tausendschön, American Pillar, Golden Emblem, Lady Galpin, a delicately beautiful pink H.T. variety and a rich crimson seedling.

On first sight, the award of the first prize in the class for a group of cut roses arranged on tabling occasioned some little surprise until it was realised that the judges were influenced by the high quality of the smaller group which was so well arranged by Messrs. B. R. Cant and Sons. Their chief varieties were Sovereign, Covent Garden, Lady French, Constance Casson and Padre. The greater wealth of bloom shown by Mr. E. J. Hicks included vases of Paul's Scarlet Climber, Ophelia, Lady Hillingdon, America and Queen of the Belgians. Mr. George Prince, who was third, had lovely vases of Padre, Climbing Richmond and Allan Chandler, with masses of the graceful Coral Cluster.

The best group of polyantha roses in pots was arranged by the Rev. J. H. Pemberton, who showed Koster's Orleans, Edith Cavell, Ellen Poulsen and Echo of great beauty.

There were only two exhibits of twenty-four blooms of exhibition roses, but both were of considerable merit. Messrs. B. R. Cant and Sons were first with an even collection of such sorts as Covent Garden, Sovereign, Richmond, Constance Casson, Phœbe, Lady French and Lady Rodway of lovely colouring. The second prize collection of Mr. E. J. Hicks contained, in Ulrich Brunner, the silver-gilt medal bloom of the trade classes. America, Chas. E. Shea, Premier and Louise Crette were also noteworthy.

Showing delicious blooms of Maréchal Niel, Mr. A. F. Goodwin was first in the class for twelve blooms of any variety. Mr. E. J. Hicks was second with America, and Messrs. B. R. Cant and Sons were third with Constance Casson. Good baskets of Evelyn and of Lady Hillingdon won a first prize for Mr. E. J. Hicks

Digitized by Google

and Mr. A. F. Goodwin was similarly placed with Maréchal Niel in the class for one basket of any variety; while Mr. Hicks was first with a basket of mixed sorts.

The decorative classes were a popular feature of the Show and the quality of the flowers so tastefully used was excellent. In the open class for a dinner-table decoration Mrs. A. R. Bide and Mrs. May were adjudged equal first and Mrs. E. Paul was second. Each competitor used Madame Butterfly. In the amateurs' section Mrs. Courtney Page added to her many artistic triumphs with a charming table, also of Madame Butterfly, while Mrs. Charlton and Miss E. Griffith were placed equal second. Mrs. Courtney Page, in the amateurs' class, and Mrs. A. R. Bide, in the open class, were the first prize winners with charming bowls of roses and Miss M. E. West had the best vase.

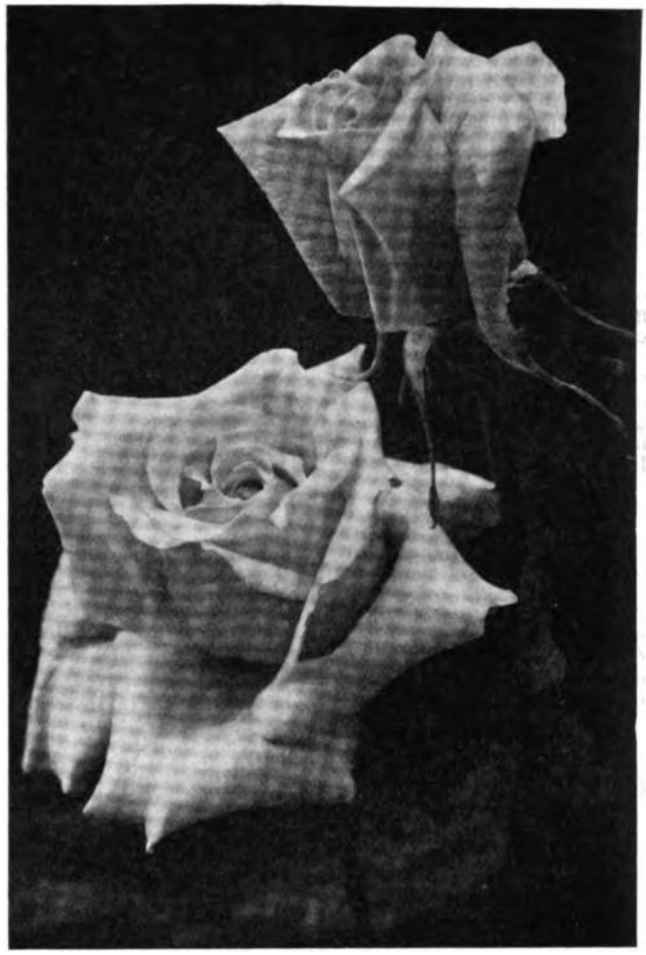
NEW ROSES.

AMERICA.—This magnificent rich vivid pink H.T. rose must now be a familiar variety to the London show-attending public, for quantities of splendid blooms have often been exhibited at the Royal Horticultural Society's Hall for some months past. No matter when shown, America has been of outstanding merit. The large shapely blooms are borne on long, stout stalks and they are of perfect form in all stages of development. Added to these perfections is the precious gift of rich fragrance with good lasting properties when cut. It is undoubtedly a rose with a great future. Gold medal. Raised by Messrs. E. J. Hill and Co. Shown by Messrs. G. Beckwith and Son.

CLOVELLY.—While it is never wise to praise unreservedly any new rose on first acquaintance, the obvious merits of Clovelly must be fully recognised. Like the foregoing it is, as shown, a fully double H.T. variety of exceptional vigour and is of good shape in all stages. It is of soft pink colouring and the broad, recurving petals seem to reflect the gracious colouring. The young foliage is a bright purple and the mature leaves are dark green. Certificate of merit. Shown by Mr. Elisha J. Hicks.

ELSIE BECKWITH.—An H.T. variety of rather more than average size and deep rose pink colouring which is lightened at the edges of the petals. The blooms are carried on good stems, but they do not seem to possess any fragrance. Shown by Messrs. G. Beckwith and Son.

SOUVENIR DE H. A. VERSCHUREN.—This seems to be a useful deep yellow H. T. rose of compact globular shape. The colour fades at the edges of the petals and the blooms have a strong, almost pungent scent. Shown by Messrs. G. Beckwith and Son.



ROSE CLOVELLY WITH BLOOMS OF SOFT PINK.

GARDENS OF INDIA

(*Continued from page* 105.)

BY SIR GEORGE WATT.

THE *neem* or *margosa* tree (Melia Azadirachta) is a constant associate of village life, because of its sacred character and its numerous medicinal virtues. The young twigs are ready-made tooth-brushes and the dried leaves can be employed against noxious insects. The *mulsâri* or *bakul* (Mimusops Elengi) is a large and beautiful evergreen tree, frequent in village sites. It produces, during the hot season, a great abundance of highly fragrant flowers and to such an extent as oppressively to perfume the neighbourhood. The flowers fall in showers, are then swept up and much valued in making garlands and as stuffing for pillows—they are sacred to Siva and as *tantric* offerings may also be placed before Vishnu. The bark is a domestic medicine much run after by ladies and the seeds yield a useful edible oil.

Seen from a little distance, the Indian village looks like a patch of forest with huts appearing here and there between the trees. Feathery bamboos, intermixed with a few trees and palms, with market gardens often seen jutting forward on high banks and with a tank or a few wells, complete the picture. But to the trees already mentioned may now be added one, the most conspicuous and remarkable in village life—the *semal*, or silk-cotton-tree (Bombax malâbaricum). A large deciduous tree, bold and aggressive, with its branches spreading horizontally from the stem, which is often buttressed and powerfully armed with great corky spines. Towards the end of December the leaves change in colour and in due course turn bright yellow and then fall in showers. Shortly thereafter, its great flowers attract attention. They are then seen to be thickly dispersed along the upper surface of the wide-spreading branches, and to stand erect. They are truly superb; hundreds of great cups, 3ins. to 4ins. in diameter, of a deep vermilion colour, with fleshy petals rigidly deflexed from the margin and having a brush of stamens rising from the middle of each. During the early morning these cups secrete a fluid of sweet acid flavour which, as the sun advances, becomes fermented and is then doubtless intoxicating. This attractive feast soon brings together all the birds and squirrels of the neighbourhood and the hilarity and squabbling that ensue are truly wonderful. Dr. D. D. Cunningham ("Plagues and Pleasures of Life in Bengal"), truly observes that "the scene is certainly one of the wildest dissipation, but the sense of moral disapprobation excited in an onlooker is tempered by the knowledge that the drinkers are doing something beyond merely enjoying themselves; for there can be no question that they are most efficient agents in securing the cross-fertilisation of the flowers."

THE HEDGE CLIMBERS.—Climbing over the hedge may very often be found the quaint American convolvulus—the *tarulatâ* (Ipomœa Quamoclit) which has pinnate leaves and crimson trumpet flowers. The *aparajita* (Clitoria ternatea), a modest little climber, hesitatingly intrudes rather than is cultivated. Its blue or white blossoms adorn the corner it occupies and are obtainable throughout the year. And yet this harmless treasure has been condemned, through a fancied immoral symbolism, from ever being offered to the gods though it may be presented to the goddess Durga.

Another trespasser of great interest is the *rati* or *gaungchi* (Abrus precatorius); this produces pods that, on ripening, burst open and reveal many small shining red peas with black faces. These peas are used by the goldsmiths as weights (they weigh 1.75 grains), and appear to be the origin of the carat weight. Throughout India they are perforated and strung as rosaries, hence their botanical name precatorius. But these harmless looking seeds, while they may be cooked and eaten, if ground down on a stone in cold water, and the paste thus obtained be hypodermically injected, are then found to originate one of the most elusive yet most virulent of all poisons.

But to bring our story of the climbers on the garden fence to a close, it may be added

Digitized by Google

that, not infrequently, beans, cucumbers, gourds, or melons are trained over it, or on a special arbour in front of the house door, or up on to the roof of the hut itself. As representative of an extensive series, mention may be made of two. One of the most useful plants of the kind indicated may be said to be the Indian broad bean, the *shim* (Dolichos Lablab), often spoken of as *lobiya* —the king of beans. So again the *petha* or *kumra* (Benincasa cerifera), the white-gourd-melon, so frequently rambles from the hedge or arbour on to the roof of the hut, that it may be said the large greenish-white mealy gourds, lying all over the huts, become a characteristic feature of Bengal.

THE FRUITS.—Assuming that an examination is being made of one of the largest and most fully equipped peasant gardens, one owned, or at least supervised by the village mali, some or all of the following plants are likely to be discovered. In one corner there may be seen a clump of the banana (or plantain as it is called in India), the *kela* (Musa sapientum), of which there are numerous cultivated varieties and races. These may be grouped into two sections (*a*) fruits eaten when ripe; (*b*) fruits eaten when green but only as a vegetable in curries. Of the ripe fruited kinds, in Calcutta, the small *Chini champa* is the most highly prized, and in Bombay the *bajapuri* or the *sonekale* or the *raikale* are all famed, the last being a large fruit with thick red rind.

In the opposite corner, very possibly, may be discovered one or two small trees of the lemon (Citrus medica, Lemonum), or of the sweet lime (C. medica, Limetta). If the owner chances to be enterprising there may also be a *pomelo* (C. decumana), or a *papia* (Carica Papaya). But both these are foreigners, the former came to India from Java and the latter from America. The pineapple (Ananas sativa), also came from America and arrived during Jahangir's time. Although found all over India to-day, it attains its greatest perfection in Northern Bengal, Assam and Burma.

The *am* or mango (Mangifera indica), is, as a rule, grown in the market garden rather, than in the peasant garden. It is purely an indigenous fruit and the better qualities are propagated by inarching. There is an immense range in the size, colour and flavour of the fruit. The finest are the Mazagon in Bombay and the Malda in Bengal, while those of Assam are the poorest. It is a curious circumstance that merit in the fruit would seem to be attained in the localities most remote from the wild habitat.

If space can be afforded, the luxurious cultivator may aim at possessing a Jack-fruit tree, the *kanthal* (Artocarpus integrifolia), grown somewhere near his house, with a platform constructed, very possibly, under its dense shade, where a friendly smoke may be enjoyed and the news of the village discussed. The huge thorny fruits of the jack (often 18ins. long), cling to the stem and the main branches in a very striking manner. The fruit is much appreciated by the Natives, but not by Europeans, who object to its smell.

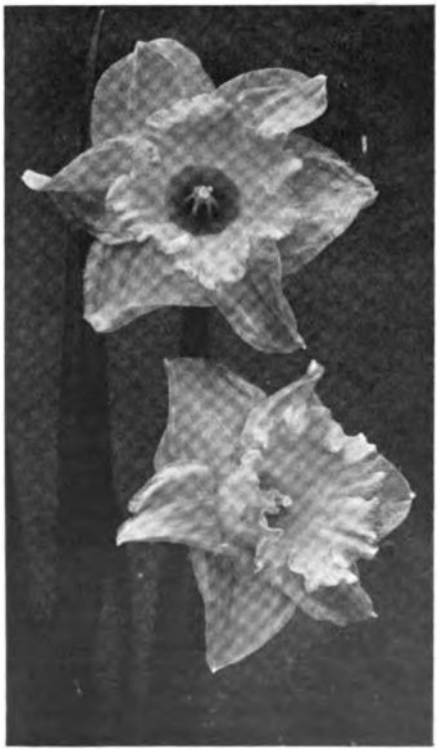
THE VEGETABLES AND SPICES.—The potato, though extensively grown in the market garden has not as yet found a place in the peasant garden. Beans and gourds are plentiful and very often a place is found for the indigenous tuber *kachu*, the *taro* or Egyptian Arum (Colocasia Antiquorum), and sometimes also for the *mita-âlu*, the sweet potato (Ipomœa Batatas), a valuable esculent for which India is indebted to America. But among and between the trees mentioned, will almost certainly be found a few of the egg-plant, *brinjal* or *began* (Solanum Melongena), a highly valued vegetable, but again a foreigner, which, in all probability, reached India from Arabia. No modern garden would be considered complete without a few chillis (Capsicum annuum or C. frutescens), most often the small, pointed and pendent kind, used mainly while still green. Once more India is debtor to America and so important has this spice become that one is surprised to learn that it only reached India in the sixteenth century.

In India the number of plants (wild and cultivated) that are systematically collected and eaten as salads (without being cooked), or as spinach (after being cooked), or which are employed as flavouring ingredients in soups or curries, are both extensive and varied. They are collectively known as *sags*. A classification of Indian gardens might be based on the *sags*. For example, the people of Northern Bengal use a very much smaller quantity of pulses than in other parts of that province, but they make up for that by the consumption of a more extensive and more varied assortment of *sags*.

(To be continued.)

THE LONDON DAFFODIL SHOW

AROUND London outdoor daffodils are few and far between, so that the several large collections at the Royal Horticultural Society's Hall, Westminster, on April 15th and 16th, when the Society held its annual Narcissus Show, came somewhat as a pleasant surprise. Even so the show fell short of earlier expectations. The vagaries and disappointments of the season are common knowledge and, unless the conditions improve materially, there will be no real display yet awhile.



A MAGNIFICENT VARIETY, NARCISSUS GOG.

Although narcissi occupied only about a third of the hall, and as is only too often the fate of organisers of special flower shows, the Royal Horticultural Society had to enlist exhibitors of other flowers to fill the hall. To the occasional visitor this considerably added to the pleasure of the visit, for, in addition to daffodils and tulips, gorgeous roses, fresh and fragrant carnations, old-world auriculas, collections of hardy flowers and enviable forced strawberries were to be seen and admired.

Nearly all the narcissi at the Show came from Ireland and Cornwall, and although a number of blooms had somewhat crimped, corrugated perianths, which all too plainly tell of a cold and backward season, there were many really magnificent examples to be seen, while in many ways the startlingly white—were it not ungallant we should have termed it face-powder white—Venetia, shown by Messrs. Barr and Sons, was the most wonderful bloom in the Show, the two exhibits by Mr. P. D. Williams in the competitive classes were certainly the most magnificent and probably the finest ever seen at any show.

In the circumstances a large number of novelties "up for award" could not be expected. In addition to the three daffodils which received awards of merit there were two vases of fascinating tulip species on the table reserved for New and Rare Plants. These tulips were both Central Asian species. Tulipa

THE BEAUTIFUL NARCISSUS VENETIA.

Fosteriana, shown by Mr. J. L. Richardson, is the giant of the species. Measured from the inside of the flower the "petals" are over 4ins. long. At first they were huge crimson-scarlet buds; then, under the influence of the warmer, brighter weather of the afternoon, the segments opened widely, till the blooms were as

Digitized by Google

large as pudding basins—most magnificent flowers. While the flowers of Tulipa Kaufmanniana paled when contrasted with those of the Persian species, they were beautiful and interesting. Of the half a dozen or so on view no two were alike, and they displayed a fascinating variation, though all were of the characteristic long pointed shape, of creamy texture, and had a distinct yellow base, giving a warm golden glow in the centre. The variable colouring included shades of scarlet, water-lily yellow and purple flushed creamy yellow. These were exhibited by Mr. W. R. Dykes.

Competition in the various classes was not usually strong, though the general quality was good. Mr. J. L. Richardson was the chief first prize winner in the larger classes. His twelve varieties of large trumpets included Mustapha, Luxor of the self-coloured sorts, with the bicolor Lady Primrose and the sulphur yellow White Emperor. Of his Incomparabilis varieties Brightling, Orange Glow and Seville were very charming. His dozen Barrii included Dosoris, Red Chief and Firetail with brilliant coronas and the chaste Queen of Hearts. His six large trumpets were especially noteworthy for the rich colouring of several seedlings and of Michael and Loyalist, and in the next class he also won chief place, showing excellent blooms of Helen O'Hara, Atalanta and White Knight. Brilliant colour was also present on his six Incomparabilis. Crœsus, Brightling and Golden Pedestal were splendid examples. Among Mr. Richardson's first prize winning six Leedsii blooms there was a vase of Pax which has a fascinating apricot-tinted corona. There was no first prize awarded for twelve Poeticus varieties—the season is much too late for these—but Mr. Richardson was awarded the second prize. The first prize twelve Leedsii were of such good sorts as those of Bridal Morn and Empire, which has a pretty frilled cup, shown by the Donard Nursery Company.

As we have already remarked, Mr. P. D. Williams staged some remarkably fine blooms. His twelve "not yet in commerce," were shown mostly under seedling numbers, as also were his twelve "raised by the exhibitor." In each class the same high quality was present. The best six varieties raised by the exhibitor were those of Captain H. G. Hawker, whose large trumpets were of outstanding value. In the class for three varieties the Rev. H. R. Meyer was awarded the first prize, and he was also the winner of the novice's class.

In the various small classes for the different sections of narcissi, first prizes were won by Mr. J. L. Richardson, Mr. F. H. Chapman, Mr. F. W. M. Copeland, Mr. W. B. Cranfield and Captain Hawker.

Gold medals were awarded to Messrs. Barr and Sons and to the Donard Nursery Company for their collections. Though the latter was somewhat the larger, the former was better arranged and of rather higher quality, though in each case the premier award was well deserved. Chief among Messrs. Barr's collection was the chaste and beautiful Venetia. It is not a large flower, but of exquisite proportions and of powdery white colour. The corona is quite small and there is a touch of pale green at the base. To all intents and purposes it is a small Leedsii variety, though we believe it has "Triandrus blood." Lavender, a larger Leedsii variety which has a pale orange rim to the tube; Andromache, a lovely Incomparabilis; Fiery Monarch, of brilliant corona; Iolanthe, a larger bicolor trumpet with a deeper rim to the tube; Brilliancy; Peter Barr, white trumpet; Mustapha, Siegfried and Royal Gold, three magnificent rich yellow trumpet varieties, are the names of only a few of the wonderful sorts on show. In addition to these Messrs. Barr & Sons staged many seedings of great charm.

Many visitors remarked with envy on the magnificence of the vases of King Alfred in the exhibit of the Donard Nursery Company, who have no apparent difficulty with this fickle giant daffodil. Gog, a gorgeous variety with a short, widely expanded trumpet of deeper colour than the yellow perianth, was also greatly admired. Among the bicolors were Felspar, Comely and Moira O'Neill. Tongario has a short wide corona with an orange rim and a starry perianth. Among the better-known sorts there were fine vases of Athos, Bernardino, Great Warley, Whitewell and Marshlight.

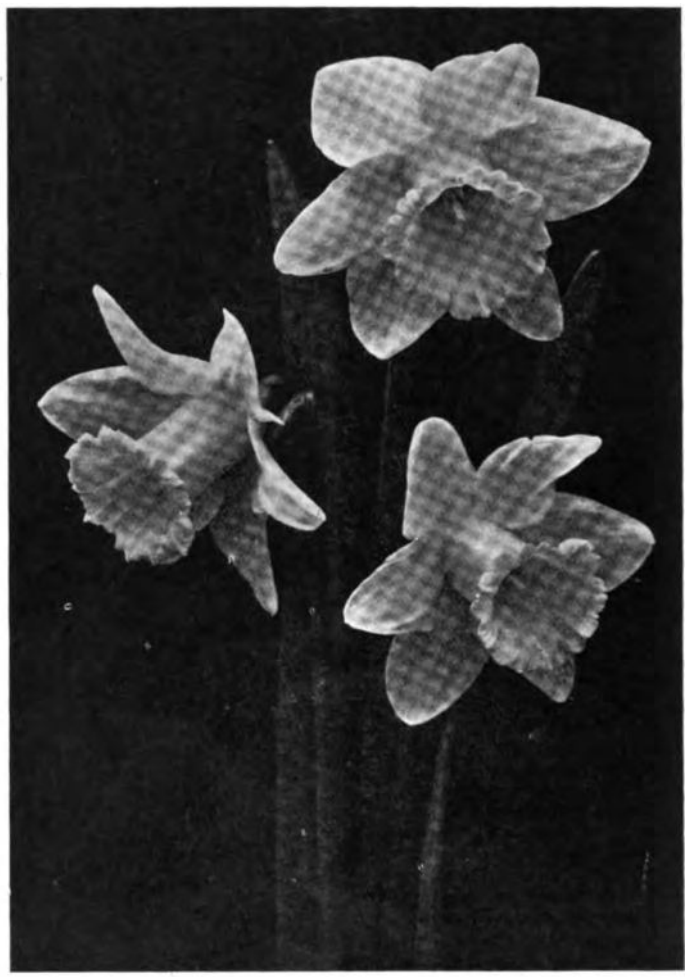
Seedling large trumpets of more than average merit were shown by Mr. J. L. Richardson, whose named varieties of this type included splendid examples of Van Waveren's Giant, Luxor and Sievenamon. Queen of the North, a small Leedsii variety which has a paper-white perianth of deceiving frail appearance, and a little corona of uncommon crimped shape and primrose yellow colour, was very fascinating. There were also several vases of Glorious, a brilliant Tazetta variety; while among the bright cupped Barri were Dosoris, Macebearer, Joan of Arc and Firetail.

The Welsh Bulb Fields Co. set up a decorative exhibit of such sorts as Brightling, Glorious and Sunrise. Messrs. R. H. Bath, Limited, included Golden East, Dominion, Golden Glory, Golden Sunrise and Golden Sunset large trumpet varieties of rich colouring. Mr. W. F. M. Copeland contributed a small collection of narcissi.

The only exhibit of tulips—which the R.H.S. combined with narcissi—was by Messrs. R. and G. Cuthbert, who had goodly pots of Rose Luisante, La Rêve, Potter, Prince of Austria, De Wet and Enchantress.

NEW DAFFODILS.

EVEREST.—A pure white large trumpet daffodil of great charm. The perianth segments are a trifle pointed and the shapely trumpet is prettily rolled and serrated at the mouth. Award of merit. Shown by the Donard Nursery Co.



THE SHAPELY WHITE PERIANTHS OF NEVIS, A PERFECT BICOLOR DAFFODIL.

NEVIS.—A perfect example of the large bicolor daffodil. The white perianth is shapely and of good substance. The sulphur yellow tube is a perfect cylinder, nicely rolled and serrated at the mouth. There is a fascinating yellow glow at the base of the tube. Award of merit. Shown by Mr. F. Herbert Chapman.

TENEDOS.—A large bicolor daffodil which has a round, substantial, milky white perianth and an exceptionally long, slightly fluted, pale yellow tube which is slightly enlarged towards the mouth and serrated with almost saw-like precision. A fascinating bloom of apparently good lasting properties. Award of merit. Shown by Mr. J. L. Richardson.

NOTES FROM CONTRIBUTORS

SOME WHITEWELL FREESIAS.

I HAVE received a delightful collection of hybrid freesias from my friend Mr. Jacob which are seedlings of his own raising. Two days travelling in the post caused them to arrive very limp, but after an hour in tepid water they revived and looked as fresh as if they had been gathered the same day. Freesias as cut flowers are very difficult to pack in order to avoid bruising. They should be tied to the bottom of the box and kept firm, but no packing put on top touching the flowers. This is easily done if only a small lot are to be sent. I wonder whether they would travel better, especially for short journeys, if allowed to become limp before packing and revived immediately they arrive at their destination. Gladioli, I believe, are packed in this way successfully.

A letter from Mr. Jacob tells me that his new variety Flame, which received an award of merit on February 26th, was not so much admired as Goldmine. I have blooms of both, and I think Flame is more attractive in its shape and its intense orange lip, and it is very sweetly scented. Stowe, a very nice open type of flower, of fine shape, not unlike Eldorado, but not so deep in colour, is of a rich canary yellow with a deep orange lip and dark brown lines on two lower segments. A good tall grower and essentially a "cut flower" variety. Canary Green, I think, is the best of Mr. Jacob's yellows, a rich canary yellow, deeper on the lower segments, three of which are slightly frilled at the edges. A very nice shape and a good scent. Lemon Green is slightly paler than Canary Green, but of entirely distinct shape, the petals being quite pointed, which makes it an attractive variety. Rose Green is a smaller type of flower, of open shape and rather pointed petals. A good variety for cutting, of a dull rose pink with a yellow lip, and I prefer it to Elegante, which has plenty of colour, but is not quite such a nice shape or type. Crocus was rather the worse for its journey, so I cannot judge it properly, but appears a good-sized open flower of an aniline blue with a white throat. It seems to be a very good colour. Mauve Queen, a large open flower not unlike La France, pale bluish violet with faint lines of the same colour in the throat and a yellow lip. This may be the best of Mr. Jacob's mauve shades. Chic, a mauve form of Mr. Jacob's Rosebud. A good solid flower of rounded shape and a white throat with a broad edge of mauve. Veteran is a yellow variety inferior to the others. Mr. Jacob remarks that it is early, very sweet, a good standby of great freedom and very reliable, hence its name. Primrose Day is a very large open flower and what I call a cream rather than a primrose shade. It has a curious shading of brown on the outer side of the petals.

These are the best of the varieties he has sent me. He seems to be strong in yellow varieties. These do not appear to break like the majority of mauve and pink shades, so he tells me. When these mauve or pink varieties break it is very rare to find one worth keeping. The best pink is Conquest, which was raised by Mjnr. van Tubergen. This I have never found to break so far, nor have I noticed any breaking in seedlings when flowering for the first time. This is the most interesting time, watching the seedlings open and hoping to find a real winner. I find so many flowers have more colour outside than inside, and just before the buds open they appear to be very rich in colour but when expanded the colour on the inside is not nearly so deep as the buds led one to expect. One has to harden one's heart when it comes to selecting the seedlings. It is useless keeping inferior sorts, and it gets more and more difficult to raise improved varieties. Ten years ago seedlings that are now discarded would have been very highly thought of, but with so many good varieties in commerce it is useless keeping anything inferior to them. I feel sure chance seedlings may give as good results as any well thought out crosses so that a beginner has a good chance of bringing out a winner, provided, of course, that he starts with good varieties that are in commerce. A certain percentage of seedlings may flower seven or eight months after sowing, but the flowers cannot be really judged then. August is the best month to sow seed, which germinates much better than if sown later. Seed sown now will take much longer to germinate, and to my mind it is only wasting over six months, as the flowers cannot be truly judged until the corms not the seedlings—have flowered. Seed sown in August will mean that you can judge the flowers eighteen months later, whereas seed sown in March will not be fit to judge until two years after sowing.—FREESIA.

A FINE COLLECTION OF WHITEWELL FREESIAS.

ANEMONE SEEMANNII

FROM what I can learn this is the proper name of a pretty hybrid anemone which I received under the name of A. intermedia and which has sometimes been offered in catalogues under the latter title. I understand its parents are A. nemorosa and A. ranunculoides, which statement is borne out by the appearance of the plant. The true A. intermedia is said to be a hybrid between A. patens and A. vernalis, but this I have no recollection of ever having seen and I do not think it is in commerce, or even still in cultivation. If it is I should be glad to know something of its whereabouts. But to return to A. Seemannii. It comes half way in practically all its features between its parents. It is rather dwarfer than A. nemorosa, but slightly bigger than A. ranunculoides, the flowers are a little smaller than those of A. nemorosa in its best forms, but larger than those of A. ranunculoides. In colour, also, the blooms are intermediate between the parents. They are of a pale yet pretty sulphur-yellow, lighter even than the charming A. ranunculoides pallida, or sulphurea as it is sometimes called. Altogether, this hybrid is a most interesting and pleasing plant, deserving to be cultivated by the many interested in windflowers of the section represented by our own wood anemone. Its requirements are similar to those of the common A. nemorosa, and it delights in a woodland soil in a partially shaded situation. It is increased by division of the roots, but I have never succeeded in obtaining seeds from it, and it is possible that seeding, if it should do so, might result in some interesting plants.—S. ARNOTT.

NOTES ON A FEW NATIVE ALPINES IN 1923.

TOWARDS the end of April last year a visit was made to the Ingleborough district, where a few British alpines of interest were seen. The locality is full of interest to lovers of Nature, as well as being the home of the late Reginald Farrer, whose enthusiastic writing has done so much to add to the enjoyment of our gardens.

Digitized by Google

The district is a rich one for botanists and geologists especially, with its various interesting outcrops and plants pertaining to them.

On the slopes of Ingleborough, about 2,000ft. up, Saxifraga oppositifolia was locally abundant in the limestone crevices, but, excepting the north and north-west aspects, the flowers were past their best. However, on the shadier side there were some fine flowering plants, including some of the darker bright-coloured forms that are more desirable for garden purposes. For a time, up at this level, the conditions were quite alpine, we being enveloped in cloud and cold driving snow, which eventually blew off and was followed by bright sun on one of our typical cold "spring" days. It was interesting to have this saxifrage shown to one in a locality only 1,000ft. up on the limestone of Moughton Fell, an unusually low altitude for this species, even in Britain. In this locality one of our rarer ferns, Lastrea rigida, is an interesting occupant, and the common heath, Erica vulgaris, was uncommonly luxurious right on the limestone. On the higher parts of the mountain was the fir club moss, Lycopodium Selago, with its interesting means of propagation by little pedicellate leafy bulbs, which can be shaken out from between the leaves. According to Hooker, this plant is "used in the Highlands instead of alum to fix colour in dyeing, also as an emetic or cathartic, but it operates violently. The Swedes employ it to destroy lice on swine and other animals." Arenaria verna, a very pretty native, but requiring very good drainage to succeed in the garden, it being very liable to damp off in the winter. Another notable member of this family, Arenaria gothica, was locally abundant; it is a somewhat doubtful native of these parts, although now well established. It seems to have spread outwards from a local railway station, and was possibly introduced in ballast from abroad. It is not included in Arnold Lee's comparatively recent and very comprehensive West Yorks flora.

In one of the "mosses" Andromeda polifolia was abundant along with the cranberry, and in damp pastures Primula farinosa, not yet in flower, abounded. Ribes alpinum was noticed in a village at the foot of Ingleborough. Daphne Mezereum, although not seen, occurs in some of the local woods well away from habitations, but there is always a doubt with a denizen such as this, which so readily grows from bird-spread seeds. It comes up in many parts of my garden, often well away from the shrubs. The white-flowered and magenta pink and darker red forms have all flowered very well this year, and, while so many flowers and shrubs have been much later than usual, it flowered well up to time and is now (April 7th) quite over. It is one of the most desirable shrubs for winter flowering, especially as it stands our usual conditions exceptionally well.

During the week-end, in walking from Settle to Leyburn, Thlaspi alpestre was seen in flower on the top of the pass over to Malham, and Draba muralis was noticed on a garden wall at Malham. Draba verna was common all over the district on walls and dry stony places, and Draba incana sparingly about Ingleborough. The blue mountain grass, Sesleria cœrulea, was frequent on the high limestone pastures. Saxifraga tridactyles, an annual, was very pretty on the walls of these upland regions, and the mossy S. hypnoides was fairly common at about 1,800ft. up. Bartsia alpina and Dryas octopetala minor are among the species native to the Malham district, but it was too early for them to be showing. Tramping across the moors to Suncliffe brought to mind that this lovely mountain valley was one of the last habitats in this region of the beautiful Cypripedium Calceolus (slipper orchid).

At Whitsuntide I had the pleasure of seeing Gentiana verna in its North of England locality at its best, finer than ever before, studding a steep grassy bank side with scores of its glorious blue flowers, for the most part fully opened out, although the day was miserably cold and drizzly. Looking over them for varieties, only one was noticed, a "slaty" blue that is the usually vivid blue kind of "flatted" down. Most of the flowers that were fully open had the white eye very perceptible. Does this show up after the flower is fertilised, as, from observations in the garden, the flowers only seem to open when the sun shines before the white eye appears? After the white eye appears they seem to keep open, sun or no sun. — T. ASHTON LOFTHOUSE, *Linthorpe, Middlesbrough.*

SAXIFRAGA OPPOSITIFOLIA LATINA.

OF the varieties of Saxifraga oppositifolia I think the variety called latina is the best. Although the colour of the flowers is not so bright as in some, they are fine and large, and then when not in bloom the foliage is attractive with its limy incrustation. Here in Northumberland it is a very reliable bloomer, the foliage being almost hidden most years with the mass of flowers. The enclosed photograph shows part of a plant on the rockery in rather heavy loam mixed with grit. Though fully exposed to the sun it is on a north-east slope so does not get too dry in summer. —R. B. C.

A FINE MASS OF SAXIFRAGA OPPOSITIFOLIA LATINA

AN INTERESTING FREAK.

TWIN PLUM TREES.

THIS interesting freak was noted in a stone of Prunus insititia. Although the stone was but little above normal size, it has given rise to two perfect seedlings.

The first photograph (which is about natural size), shows the stone as it was forced above the soil by the two radicles, and the second, just after the shell had fallen away. It will be seen that each pair of cotyledons has its own testa, and the third shows the two individuals, one of which is slightly the stronger, but both perfectly healthy.

The two plants are just as far advanced as other normal seedlings of the same sowing.

Although double kernels are fairly common in many such stones, nuts, etc., usually only one of the pair has the power of germination. —L. Buss.

THE TRIUMPH OF MOSS FIBRE OVER SOIL FOR BULB GROWING.

TO all those interested in the growing of bulbs in moss fibre the Royal Horticultural Society's fortnightly show of April 8th and 9th should have been one of the most interesting held this spring. The most striking group in the exhibition was, without doubt, the beautiful display of Darwin and May-flowering tulips and Dutch iris grown in bowls of moss fibre and exhibited by Messrs. R. H. Bath of Wisbech, who received the gold medal of the Society for this group. One might almost call it "The Triumph of Fibre over Soil," as the bowls of tulips were examples of the most skilful cultivation, for, as we all know, it is not easy to get Darwin tulips to flower under glass and to retain the glorious strength of stems, foliage and bloom, as did those that Messrs. R. H. Bath exhibited. The height of many of these tulips measured 36ins. These blooms immediately attracted one's attention on entering the hall by their intense colouring and gracefulness, and the mass of forty-three different colours which all seemed to blend were given depth by quantities of cut brilliant blue chionodoxas placed in masses low down among the tulip bowls. For indoor decoration it would be hard to find any more attractive flower than the Darwin tulip, and when grown in masses of twenty or thirty in a bowl of fibre, they are seen at their best and will easily last from a fortnight to three weeks in any well ventilated room. It was impossible not to make comparisons between these graceful Darwins grown in fibre and the early double tulips shown by Messrs. Dobbie, where five bulbs were grown in a 5in. pot and had a most prim and proper Victorian air about them, or the early singles grown by Messrs. Cuthbert, also fives in 5in. pots, the sedateness of which, compared to the Darwin collection, was most marked, and one at once realised that for forcing purposes and decorativeness, the day of the single and double tulip grown in pots has departed. Among the lilacs, yellows, flame, chocolates and pinks of the Darwins there is a vast choice of colour, enough to suit every taste and colour scheme required for rooms. Among the soft subdued tones a group of Blue Bird (a pale lilac) mixed with Marconi (damson) and W. A. Verbrugge (a deep claret), is very striking, while for vividness, Bartigon, a cherry coloured bloom with white centre, Mrs. Farncombe Sanders and Van Poortvleit run each other very close. Donders (a brick red,

Digitized by Google

with blue-black centre), and Eclipse (crimson), were also attractive. The slim pointed yellow May-flowering bloom of Avis Kennicoth is a wonderful foil to the Tulipe Noire, while Bronze Queen (an old gold colouring) and Golden Bronze combined with the dusky Dom Pedro, are delightful. All these tulips mentioned range from 1s. 6d. to 3s. per doz., barring W. A. Verbrugge, which is still 12s. per doz., and all can be grown in fibre with splendid success by amateurs. Likewise the Dutch iris, ixias, montbretias, the Gladiolus primulinus hybrids and other sorts, and it is not yet too late to start these. The difficulty is to get deep enough bowls to grow gladioli in. Personally, I use deep old copper saucepans with their handles removed and the colouring of the gladiolus bloom reflected in the polished copper in charming.

The great secret in growing bulbs in this compost is to get it the right dampness. When mixing small quantities, half fill a bucket with fibre and shell (bought mixed together), then fill the bucket with water and leave for a day. The next day you will find that the water is all absorbed and that you can rub out the lumps in the fibre without getting all the dust up your nose. The right dampness required is when if you take up a handful and squeeze it, only a few drops of water fall out, and also soak your charcoal before placing on the bottom of the bowl and covering with fibre. Place 2ins. or 3ins. of fibre in the bowl, do not press down hard, as if pressed tight the roots cannot work freely in the fibre, place as many bulbs as possible in the bowl, cover to within half an inch of the rim, seeing that the fibre is well tucked down between the bulbs. When the bowls are filled place in an airy room or on shelves in potting shed and leave for three or four weeks to form roots. During this time they will require very little attention.

After they start to grow they should be looked at every three or four days and great care must be taken that the fibre is kept moist, but never sodden or so wet that if the bowl is turned on its side water runs out. On the other hand, if once they become dry, even for half an hour, the pores of the roots close up and the bulbs will often become "blind," this is especially the case with tulips. It will be quickly noticed if all the moisture has been absorbed, as the fibre will become dry on top and of a light brown colour. When the bulbs have grown 1in. above the fibre they should be brought into strong light and until they flower, be given as much light and sun as possible, otherwise the foliage becomes long and weak and the flowers are poor in colour. It is important to turn the bowls often, as if standing on a windowsill in a room the flowers are drawn towards the light and grow all crooked. Those who have not glasshouses should not despair as, with care, I have been able to produce as good, if not better, blooms than many gardeners with glass; and my only forcing house has been a moderately heated linen cupboard, by the help of which I have hyacinths in bloom early in December. They are placed in the cupboard at night and removed to the light by day. All bulbs forced in such slight heat will flower splendidly the next spring if planted out in the garden.—EVELYN VENNING.

CORRESPONDENCE

THE SPURGE LAUREL.

I AM obliged to "R. J. S." for calling in question my statement that the flowers of this daphne are scentless (page 248). If I have erred, it has been in good company, because they are described as "green and scentless" in Sir Joseph Hooker's edition (the fifth) of Bentham's "British Flora," and as "yellowish green, with no odour" in Mr. Bean's "Trees and Shrubs."

However, I determined to test the question once more, and one evening between 6 p.m. and 7 p.m. I cut a flowering branch of spurge laurel. I could perceive no scent in the blossoms in the open air, so I brought the spray into a warm room and placed it in water. Two hours later I asked two ladies to smell the flowers. They both declared that they could smell nothing. Next day I submitted the same flowers to be tested by six persons. Two of them, a man and a young girl, pronounced them to be fragrant; if the other four and myself had been put on oath we could not have affirmed that we perceived anything more definite than the scent of fresh foliage. Of course, I accept "R. J. S.'s" assurance that the flowers of his daphne were strongly sweet. It is possible that there are fragrant and scentless varieties?

The olfactory apparatus of many of the lower animals is infinitely more sensitive than that of human beings. A dog will follow unerringly the trail of his thickly-shod master, and insects may be attracted by the odour of flowers which our grosser faculties cause us to consider scentless. The late J. H. Fabre has described the remarkable result of a female peacock moth (Attacus pavonina, Linn) emerging from a cocoon in his laboratory. It was placed under a wire gauze bell, and presently his house was beset by a crowd of males, attracted, as he suggests, by a subtle effluvium from the imprisoned female.

"The aggregate of visitors during eight evenings amounted to 150, an astounding number when I consider how hard I had to seek during the following two years to collect material for continuing these observations. Though not impossible to find in my near neighbourhood, the cocoons of the great peacock moth are at least very rare, for old almond trees on which the caterpillar feeds, are scarce in these parts. . . . My 150 moths came from afar—from very far, within a radius of perhaps a mile and a half or more. How did they know about what was happening in my study?" (Fabre's "Life of the Caterpillar" pages 245-280.)

Fabre was always thorough in observation and experiment. He found that when he shut up a female peacock moth within two or three airtight boxes, no males were attracted to his open window, the sure inference being that no odour or other "wireless" had been transmitted.—HERBERT MAXWELL, *Monreith*.

WHITE CYCLAMENS.

IN your issue dated March 22nd there is an illustration of "The Giant White Wonder Strain of Cyclamen," and a paragraph about it saying "There is a distinct need for a really good white strain, etc." I enclose two photographs of a white cyclamen, the smaller plant is a seedling of the large one, which is eleven years old and was found a tiny stray seedling (we had no cyclamen then in our greenhouse), on the rubbish heap by my head gardener, Mr. Ford. It is pure glistening white, the petals on the younger plant being 2¾ins. long, very floriferous and very sweetly scented. I intend to exhibit the plant at the Royal Horticultural Society's Hall next year.—AUGUSTA WRIGHT, *Lapworth, Warwickshire*.

A SEEDLING OF A FINE WHITE CYCLAMEN.

[Unfortunately the other picture would not reproduce satisfactorily.—ED.]

HERBACEOUS BORDERS.

CAREFUL planting is certainly called for in order to preserve continuity of bloom in the herbaceous border throughout the season; and to avoid more or less unsightly gaps for long periods it is wise to dispense with many plants that are in themselves interesting, but whose flowering period is of all too short duration. I do not, however, agree with Mr. Thackeray Turner with regard to the inclusion of the lupin in his examples of undesirable plants for herbaceous border purposes. I find the perennial lupin one of the best plants to grow in such a border owing to its comparatively long period of flowering. With me, it begins to show colour, in normal seasons, at the end of April, and continues in bloom throughout the summer. From time to time the old flowering stems are cut down as they become spent and vigorous young spikes are produced to carry on the flowering period. Such a fine range of colours can be obtained with the varieties now in commerce, that the perennial lupin has become one of the most useful plants in the border. The more recently raised varieties and hybrids are distinct acquisitions. The colours range from dark blue and purple to delicate tints of rose and fawn. My soil is a strong, heavy loam and probably one of the reasons the lupin does so well with me is due to this fact. The yellow hybrid Sunshine is a particularly fine bright yellow, did excellently well in my garden last season and was much admired. It commenced flowering quite early and continued in bloom right throughout the season, being in flower, in fact, during the autumn.

With regard to the use of annuals for the purpose of keeping the border full of bright colour, a restricted use of them to such an end may be useful. It is very necessary, however, that if full advantage is to be taken of them in the manner indicated, they should

Digitized by Google

be grown, as Mr. Turner suggests, in a little nursery, and transplanted in due course. Otherwise the very object for which they are to be placed in the border is defeated. Unfortunately, most annuals get very untidy-looking as the season advances, and it is debatable whether their use to any considerable extent is really worth while.—HOWARD H. CRANE, *Eastcote, Middlesex.*

A FIFTEENTH CENTURY GARDEN.

THE following extract from "Ane singular lernit proloug of the description of May," by Bishop Gavin Douglas of Dunkeld is perhaps worth quoting, for the picture that it gives of a flower garden at the beginning of the fifteenth century is not altogether conventional, and though it is not very great poetry, yet there is a certain richness and vigour in the description that makes it pleasant reading in these days of protracted winter and tardy spring.

"Ive leavis rank ourspread the barmkin wall,
The bloomit hawthorne clad his pikis all;
Forth of freshe burgeonis the wine grapes ying
Endlang the trelleis did on twistis hing
Soft balmy verdure after balmy showers
On curland stalks smiling to their flowers.
Beholdand then sae mony divers hew,
Some perse, some pale, some burnet and some blew,
Some grese, some gules, some purpure, some sanguane.
Blanchit or brown, fauch-yellow many ane,
And some depart in frecklis red and quhite,
Some bricht as gold with aureate leaves light.
The daisy did unbraid her crownal small
And every flower unlappit in the dale,
In battil grass burgeons the banewort wild,
The claver, catcluke and the cammamild;
Seyr downis small on dent de lion sprang
The young green bloomit strawberry leaves amang.
Gimp geraflours their royne leaves upshet,
Freshe primrose and the purpour violet.
The rose knoppis, tetend forth their head
Gan chype and kythe their vermel lippis red;
Crisp leaves some sheddand, baith at anes
Cast fragrant smell amid fra golden grains.
Heavenly lillies, with lockerend toppis white
Opened and shew their crestis redemite."

The dandelion heads that the poet, rather unexpectedly, includes in his list were evidently growing among wild strawberries or he would hardly have noticed them with such serenity, though they are really rather beautiful if you can look at them with detachment and forget their diabolical efficiency as weed disseminators.

Bishop Douglas was very prolific in names of colours, and it is perhaps a pity, as Miss Jekyll has regretted in one of her books, that so many of the old colour names have become obsolete, seeing that our present-day vocabulary of colours is barely adequate to the demands made upon it, especially in describing flowers. Unfortunately, it is notoriously difficult to discover exactly what colour many of the old words described. *Royne* is hopelessly obscure, for it seems only to occur in this poem. It is perhaps connected with the English *roan* and may mean a pale, rather brickish red. *Perse* in Bishop Douglas' list was some kind of blue, most probably a deep purple blue, and together with *burnet* (reddish brown), which is extinct except as the name of a plant and a moth, might have been usefully retained. So, too, might "sanguine," which meant a slightly brownish red, rather than the shade of crimson which we now call "blood-red." "Black and blue" is a good description of the dark varieties of Aquilegia vulgaris, but white and blue columbines may have been meant, for one text gives "blank and blue" (though this is an unusual use of *blank*) and the two words blaec (black) and blac (white) were already confused in Anglo-Saxon, both being probably connected by the idea of lack of colour.

Other colour words used by Bishop Douglas were *granit* and *punic*. Granit or garnet is the colour of the pomegranate seed and usefully expresses the idea of clearness and translucency as well as the shade of red, punic was probably crimson-scarlet, for the French *poinceau*, the field poppy, is derived from the same source.

It might be convenient to have back some of the old colour words, but there is an uncomfortable, Wardour Street feeling about such reintroductions and probably a more extended use of the "repertoire des couleurs" would be a safer and more feasible alternative. F. A. HAMPTON.

Pikis, thorns; *perse*, blue, probably dark purplish blue; *grese*, grey; *sanguane*, brownish red; *fauch-yellow*, fawn-yellow; *battil grass*, lush grass; *catcluke* ("cat's claw"), bird's foot trefoil; *Seyr downis small*, much small down; *Gimp geraflours*, neat carnations; *royne leaves*, (?) pale red leaves; *chype and kythe*, open and show; *lockerend*, curling like locks of hair; *redemite*, crowned.

HYACINTHS IN SPAIN.

I WAS interested in the note and illustration of a prolific hyacinth in your issue of March 29th (page 213).

The heavy rainfall we have had this winter in the south of Spain has evidently suited hyacinths. Two years ago I planted 100 bulbs, fair sized, which were left in the ground during the summer and received no attention beyond a light top-dressing this autumn. This spring these 100 bulbs produced 273 blooms, of which about half were full size. Hyacinths planted last autumn were exceptionally free flowering, and I counted 106 and 103 bells on single stalks of the variety Queen of the Blues: all the bells were perfectly developed, except about a dozen at the top of each spike, which had a slightly green tinge. Hyacinths begin to bloom here about the middle of February and last about five weeks if we have hot dry weather, and seven weeks if cloudy with a moderate amount of rain.—CHRISTOPHER SANDEMAN, *Jerez de la Frontera, Spain.*

PERENNIAL CONVOLVULUS.

I VERY much enjoyed "J's" account (page 233) of his struggle with Convolvulus althæoides, as I have had a fight with it too—in fact one of the reasons I had for wanting to leave a certain garden was because it knocked me out so completely, and had no generosity about its triumph. In case "J." is also feeling humiliated in its presence (in spite of his noble resistance), I beg of him to plant a root—a single thread will do—of Scutellaria baicalensis next door to the convolvulus. He will, of course, have no garden left to put anything else in, but the battle between these two devouring brutes would be of such overpowering interest as to eclipse any disadvantages. The scutellaria is the most innocent looking little thing, about 6ins. high, with blue flowers, but in two years it swallowed about 8ft. by 10ft. of rockery, making a tight, dense mass of hard, wiry, ineradicable roots, and dealing death to everything in or under its way.—M. L. W., *Bath.*

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Naturalising Anemones (FELSTED).—Anemone apennina (the Blue Appenine Windflower) thrives among deciduous shrubs, and grows as freely naturalised in the wild garden and woodland as does our native A. nemorosa.

THE GREENHOUSE.

Pelargoniums Attacked (C. M. W.).—The foliage sent has been attacked by plant bugs and probably also by aphis, traces of which are still present on the leaves. Fumigation should be resorted to as soon as these pests make their appearance.

TREES AND SHRUBS.

Shrub to Form a Screen (L. H. C.).—The hybrid barberry, Berberis stenophylla would be an ideal plant for such a position. it is evergreen and gives a wealth of rich yellow blossoms in April and May.

FRUIT GARDEN.

Cherry Trees Unsatisfactory (E. F. W.)—The condition of the trees which our correspondent describes, is a very common one; in the case of old specimens growing in an uncongenial rooting medium, such as an irony gravel sub-soil. It would require a very lengthy reply to describe the effect and just how it comes, in detail. But briefly, a swelling is caused in the bark and, when the alburnum is dead, the bark splits, and decays, causing, in appearance, ulcerated canker. In younger trees the washing of the bark with soapsuds will lessen the trouble, coupled with careful treatments at the roots—top-dressing with fibrous loam, but not over feeding. In the case of old specimens it is best to discard them and plant young ones. Tar and clay, mixed, should be pasted on all parts of bark cut away where there is exudation.

Netting Fruit Trees and Planting Iris stylosa (D. W., Surrey).—After the blossom and resultant fruits are duly protected from frosts and birds, the trees should be fully exposed so that the air and birds can have access to them. It is quite wrong so to enclose the trees all the year round. The iris should be transplanted in late spring or early autumn.

VEGETABLES UNDER GLASS.

Tomato Plants Attacked (E. M. N.).—The tomato plants are attacked by the fungus Phytophthora cryptogœa, the spores of which are in the soil. This form of damping off may be kept in check by sterilising the soil and by giving all the light and air possible, at the same time avoiding at all costs having the soil too wet.

MISCELLANEOUS.

Birds Destructive (T. I. W., Eastcote).—There are two ways of preventing the birds pecking out and destroying the moss between the stones where the alpines are growing. Our correspondent should procure some white thread—not black—and, with the aid of tiny pegs fasten down the thread in short lengths close to the moss and rather less than 1in. from strand to strand. The birds will peck at the thread and, if they cannot carry it off they will become scared. If they do take it away it will probably become wrapped around their beaks and this will scare them. Only a few places need be thus treated. The other preventive is to scatter a small quantity of Sanitas powder on the moss. Whether it be wet or dry it will be distasteful to the birds. They are hunting for grubs.

Names of Plants.—W. T.—Saxifraga apiculata.—C. K.—Polygala Chamæbuxus, "Bastard Box."

Digitized by Google

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Dwarf Beans.—A few lines of these should be sown on a sheltered border, unless some means of protection is at hand whereby the plants can be made secure from frosts. It should be borne in mind that very little protecting material will be required by the time the plants appear, and let us hope it will not be needed, because last year dwarf beans were more or less a failure. A fortnight hence a liberal sowing may be made. The distance between the rows should be about 18ins., and a foot of space allowed in the lines. Canadian Wonder is still a good variety, and if allowed ample room to develop will produce a fine crop.

Perpetual or Spinach Beet.—This is an excellent substitute for ordinary spinach and, moreover, it is usually a success when other sorts are a failure. Sow thinly in rows 1ft. apart and thin out the seedlings to 8ins.

Lettuce.—Seeds that were sown in a cold frame have produced strong, healthy plants, and some of them may be transplanted in the open border. Continue to sow a little seed at fortnightly intervals of both the cabbage and cos varieties.

General Work.—Complete the planting of potatoes, plant out cauliflowers. Sow seed of scorzonera, chicory, cardoon and sorrel, while herbs of all kinds may still be sown. Carrots growing in frames should be slightly thinned, and air admitted freely when the weather is favourable.

THE HARDY FRUIT GARDEN.

Young Trees planted at the base of walls will need close attention and careful disbudding if the foundation for a well formed specimen is to be obtained. Sufficient basal shoots should be retained to prevent bare spaces in the centre of the tree, and growths selected for extension purposes well placed so that there will be no difficulty in tying them to the wires. If one or two shoots in the centre become too vigorous, they should be removed, whereby the energy of the tree will be more equally distributed. Keep a watch for insect pests, especially green and black fly, and directly any are seen spray the trees at once with an approved insecticide at slightly under the strength prescribed by the makers.

FRUITS UNDER GLASS.

Peaches and Nectarines.—The trees will now require constant attention, such work as disbudding, thinning the fruit and tying in the shoots being carried out gradually so as not to upset the flow of sap. In the earlier houses the fruit is near the stoning stage, and here the night temperature should be about 60° with a rise of a few degrees during the day, but if the weather is bright the thermometer may go higher and no harm will accrue. Never allow the roots to become dry, and when it is decided to afford water to the border, give a slight sprinkling of Thomson's Manure or Le Fruitier. For trees producing a good crop a little manure applied often should be the rule. Keep the atmosphere moist by damping the paths occasionally, and early in the afternoon close the ventilators and give the trees a thorough wetting with the syringe or garden engine. This is important in keeping down red spider, because once this pest appears it is most difficult to keep it in check and well-nigh impossible to eradicate it till the end of the season. Whenever the weather is favourable ventilate the house, but always avoid cold currents of air passing over the trees.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbages.—Plants raised from seed sown early in the year and brought on under glass should now be sufficiently advanced and hardened off to be planted out. Lines should be drawn out 18ins. apart with the corner of an ordinary draw hoe—a triangle-shaped hoe is better for the work if such is available. These early plants should be thoroughly watered first, then lifted in such a way that a good ball of soil is obtained with each. The plants should be set 15ins. distant from each other in the lines and planted with a trowel. The object in taking a little extra care with the planting of early vegetables is to give the young plants as slight a check as possible. This rule holds good in the growing of all young vegetable plants in their early stages.

Potatoes.—The season is advancing, and the work of planting should be forwarded without delay. The distances for planting vary somewhat according to the varieties, but oft-times one has to regulate the distance according to the area available. A good average distance between the lines is from 2½ft. to 3ft. and from 8ins. to 12ins. between the sets. Robust growers and those in positions where they are likely to be drawn should be allowed more space.

THE FLOWER GARDEN.

Antirrhinums raised from seed sown in autumn and wintered in boxes under glass or growing in cold frames should be set out now in beds or borders. Plants treated thus bloom in June, and so prolong the display of a very effective and accommodating perennial. It may be interesting to state that antirrhinums when fairly established do not suffer should a dry, hot spell of weather come.

Poppies.—Many spaces may be filled and fine displays obtained on hardy plant borders by the judicious use of hardy annuals. The Giant Double Chamois Rose Poppy is suitable for the middle or back places in large borders. It has massive individual flowers which are finely coloured. Papaver umbrosum and the tulip poppy are two very attractive kinds when seen *en masse*, and somewhat resemble one another in colour and height. The Shirley poppy, too, should certainly be included.

THE HARDY FRUIT GARDEN.

Black Currants.—It is of the utmost importance that everyone should be most assiduous in the eradication of the big bud. If bushes cannot be kept free by hand picking, they should be cut down and every portion of the wood burned. The variety Seabrook's Black is said to be immune from this disease.

Raspberry plantations should be kept clear of weeds by the judicious use of the hoe and rake.

FRUITS UNDER GLASS.

Peaches.—Houses should receive attention by thinning the fruits and shoots in succession, and each individual will require to take into consideration whether his trees have flowered freely and set well, and also whether the growth is vigorous or weak, and thin accordingly. The fruits left after the final thinning should be situated something like 12ins. apart. The trees should be syringed daily, first in the early morning and again in the afternoon to keep the foliage free from insect pests.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Aotus gracilima.—This beautiful Australian shrubby plant is now in flower, and it can be easily propagated at this time by means of small, half-ripened twiggy shoots. These root readily in pots containing sandy soil if stood under bell glasses in a cool greenhouse. This plant is best grown in the form of a small standard, as the long slender drooping shoots are then displayed to the best advantage. The young plants should be pinched once, and two or three of the resulting shoots should be kept tied up to a stake. All lateral shoots should be rubbed out until the plant has attained a height of 2½ft. to 3ft., when the leading shoots should be stopped, and laterals allowed to develop to form the future head of the standard. This plant only requires cool greenhouse treatment during all stages of its cultivation.

Streptocarpuses raised from seed sown early in the New Year, should be kept moving by keeping them pricked off in pans or boxes containing fresh compost, which, in their younger stages, should be of a light character. When large enough they should be transferred singly to small pots and potted on as required. They should, by the end of summer, make nice plants in 48-sized pots, and will prove very useful for the greenhouse at that time. Young plants treated in this manner last year and kept on the dry side during winter are now making fine specimens in 6in. pots and will prove very useful towards the end of May. Seed may still be sown, and if the young plants are grown on steadily they will make good plants for next year. Streptocarpuses in their younger stages should be grown in a temperature of about 60° and as they approach the flowering period should be accustomed to cooler conditions. They are very subject to attacks by mealy bug and begonia mite. The plants are difficult to sponge, so a brush must be used to get rid of mealy bug. Begonia mite can be prevented by the use of the sulphur vaporiser.

Gloxinias raised from seed early in the year should have the same treatment as advised for streptocarpuses. Plants grown from dry corms started early in the year should now be ready for transferring to their flowering pots, which, for well grown examples, should be 6ins. in size. Gloxinias enjoy a rich light compost, to which should be added some old mushroom bed manure, or dry cow manure. As in the case of streptocarpuses, begonia mite should be guarded against.

Tuberous-rooted begonias raised from seed, should be kept moving by frequent shifts into seed boxes. During May they should be ready to plant out on a bed of rich soil in cold frames; from which, later on, a portion of them should be potted up for the conservatory. The plants should flower towards the end of summer when they make a good succession to the plants grown from dry tubers.

Achimenes that were started in boxes and have made several inches of growth should now be placed in their flowering pots or pans. Some of the more slender-growing varieties are excellent for filling hanging baskets. The plants require very careful watering for some time until they have made a quantity of new roots.

Lindenbergia grandiflora is a useful plant for flowering during the autumn and winter. It can be propagated at this time by means of ordinary cuttings or root cuttings. Being nearly hardy it requires perfectly cool treatment during all stages of its cultivation.

J. COUTTS
Royal Botanic Gardens, Kew.

BOOK REVIEW

MANUAL OF CULTIVATED PLANTS.

STILL another work from the pen of L. H. Bailey has come to hand, to outshine, if possible, his last on "The Cultivated Evergreens." This present volume is a manual of Cultivated Plants (Macmillan Company, 31s. 6d. net), which deals exclusively with the domestic flora of America. He is a most prolific writer, and one wonders how in one short span he is able to collect his data, so accurate in all its details, and to present it in such a condensed form to the horticultural world at large. American botanists, and also those interested in the study and the general practice of horticulture elsewhere, owe much to the skill, knowledge, enterprise and untiring energy of Dr. Bailey, who has probably done more to promote and further the interests of horticulture in America than anyone. The present manual is the result of forty years' collection of data, and the information contained therein is not merely a compilation of material but is the direct outcome of the study and the growing of many actual specimens dealt with. One hundred and seventy natural families, including 1,246 genera and 3,665 species, are treated, embracing the whole vegetable kingdom. The author has followed the usual systematic rules commencing with the Thallophyta of which he only mentions one genus (agaricus) then on through the Bryophyta to the Vascular Cryptogams and the Gymnospermæ, with the Angiospermæ or Flowering Plants following on as a natural sequence, and being divided into the Monocotyledons and Dicotyledons. The Dicotyledonæ are subdivided into the Choripetalæ, including the Polypetalæ and Apetalæ, and the Gamopetalæ (those flowers with fused petals). Everyone will not agree with his system, but on a broad general basis it is an extremely good one, as his treatment and arrangement of the families enables the various points of affinity, resemblance and linkage to be established. One obtains the broader idea of the phyletic relationships which exist between the groups, serving to present in a more natural manner what is, after all, simply a convenient mechanical system of classification. The manual contains a mass of facts which it is not suggested should be a burden on the memory, but which, if treated and used in a proper way, will gradually lead one to form one's own ideas of the many features and characteristics by which the numerous natural families are defined. The more familiar the reader becomes with the flora, the more proficient will he become out in the field in "spotting" his plants. At the commencement of the flora a key is to be found to the innumerable families, along with a few well-chosen words to the student on the use of a key. Once the family is made certain of, it can be turned up in the flora, where a paragraph will be devoted to it, enumerating its distinctive features, such as distribution, habit, fruit and flower structure. A generic key is also provided under each family, and the genus is dealt with in a few words, after the same fashion as the family. Finally, to determine the species, a specific key is to be employed. Such is the usual mode of procedure in any systematic book. Bailey, however, is exceptionally concise and to the point in his remarks, scientific terms being employed throughout, resulting in a thoroughly accurate description of each plant under discussion.

To a botanist, and one trained in systematic descriptive terms, the book will present no difficulties. To the horticulturist, also, the manual should prove worthy of regard, since it can be used with ease and rapidity by him, as a comprehensive list of terms or names with explanatory notes to each is provided in the first few pages. In this way, then, the horticulturist will be assisted in his scientific training, in that he will gradually acquire an accurate method of working which is so useful in discrimination. A useful glossary of authorities for binomials is also provided. A few notes on the making of a herbarium should prove exceedingly helpful to those who wish to pursue the study a little farther than the ordinary person. The hints given are all the result or outcome of personal experience, and as such are to be relied on. The index to be found at the end of the manual is copious, and is, of course, of great assistance.

As Dr. Bailey himself remarks, "The book is somewhat limited in its scope, but blemishes occurring in this edition will probably be corrected in subsequent ones." The manual should open a new vision and field to the botanist, insomuch as the domestic flora of the country is treated, which should prove a fruitful field of biological research. The horticulturist should benefit by acquiring accurate methods and a keen scientific knowledge of the plants which he deals with daily. It is a book which the student would do well to have if his pocket can run to it, as it presents a new branch of the subject. The idea of a domestic flora of cultivated plants is an excellent one and one which should be fostered in all other lands.

A few pages of illustrations in the form of line drawings are well done, depicting various structures and points of interest pertaining to the natural families and genera. The publishers are to be congratulated on the standard of accuracy and excellence of the work.—G. C. T.

The Iris Society—It has been decided to admit to the Society (founded 1922), all who are interested in irises and who wish to join it. Ladies will be eligible and the subscription is 10s. 6d. annually. Particulars may be obtained from the Hon. Secretary, Mr. George N. Bunyard, The Royal Nurseries, Maidstone. The object of the Iris Society is: "To spread more widely the knowledge and love of irises, to make their cultivation easier and more successful and to encourage the introduction of new species and the raising of new and improved varieties." As the Society is still in its infancy, it cannot at first offer the advantages which we hope it will eventually bestow. The Committee expects to issue very shortly the first number of an Iris Journal to which many of the best known iris growers are contributing short papers on "How to Grow Bearded Irises." Such experience should be very valuable to those taking up the cultivation of irises, as the writers live in different parts of the country, so that some of them have had to struggle with indifferent soils and unfriendly climates. The Journal will be issued free of charge to members and to members only.

The Fête des Narcisses.—On the last day of May and the first of June, the beautiful Fête des Narcisses, a Swiss floral festival which has always commanded the interest and admiration of Englishmen, will take place at Montreux. Last year, when the Fête was held a day or two later, a Russian Ballet figured among the attractions, and there were exquisitely decorated cars depicting peacocks, butterflies and the like. Lovers of the artistic and beautiful will, it would seem, be far from disappointed on the coming occasion since prospects generally are more than pleasing. In fact 1924 is almost a parallel to 1922 when Sir Richard Temple, on May 27th, wrote to the Times from his much-loved Montreux on Lac Leman: "And now as I write, though there has been an inclement winter here as elsewhere, I am looking out from my window on to a cloudless sky under which the snows are dazzling white and the sheen on the hills perfect; the lake is glassy still with just a suspicion of cool breeze; every spring flower is in bloom under the trees and in the hillside grass; the narcissus is already carpeting the hills with patches of white and the roses, so varied and profuse here, are waking into blossom literally everywhere. In a week the whole place will be a wonderful blaze of colour ready for the Fête des Narcisses." Thus, while the actual Fête itself is so beautiful as to beggar description, the words of Sir Richard, who talks of Montreux, with its old picturesque architecture, as Switzerland in excelsis, will fire the imagination at the close of a winter similar to that experienced in 1922.

The American Iris Society.—At the meeting of the Directors of The American Iris Society on March 21st, 1924, discussion centred upon the importance of regulating the introduction of novelties and the even greater importance of giving almost immediate official recognition to such varieties as prove worthy. At present a symposium is published five years after the introduction of a variety, but with the registration of almost 200 varieties in 1923, a more immediate report seems most desirable and a committee has been appointed to consult with Prof. A. P. Saunders, Secretary of the American Peony Society concerning a policy which may prove practical to both societies.

Dr. Gleason, of the New York Botanical Garden, reported plans for the rearrangement of the 900 varieties in the present iris test garden that will lead to the development of two plantings, one in alphabetical arrangement for purposes of identification, the other according to color in order to show the value of irises for display. Fertiliser tests have been initiated at Cornell and it is hoped that similar experiments may be carried on at New York and elsewhere.

The publication of four bulletins each year is strongly advocated and Bulletin 10, "Irises for the Beginner," is to be re-issued for general sale.

In 1923, our fourth year as an organisation, there were some seven hundred members in this country and abroad, and our policy of co-operating in many local exhibitions each year and of restricting our expenditure largely to the publication of bulletins, has made for a gradual but steady growth. The dues are $3.00 a year and anyone interested in irises, or even just a garden, is eligible to membership.—R. S. STURTEVANT, *Secretary, Wellesley Farms, Mass.*

Warning Against Spraying Fruit Trees While in Flower.—The Council of the Royal Horticultural Society desires to call the attention of fruit growers to the important part played in the production of our fruit crops by bees and other winged insects which visit the flowers. Experiments have proved conclusively that in most kinds of hardy fruits heavier crops are produced when the pollen of one variety is carried to the flowers of another variety of the same kind. Unless this is done, many varieties will produce no fruit and almost all varieties bear better crops if pollen of some other variety is brought to them. The pollen is carried by the wild and hive bees and by other winged visitors to the flowers, and by these alone. Sprays applied for the destruction of pests of fruit trees at times when these essential insects visit the trees will, naturally, cause the death of friends and foes alike, and the Council feels sure that it is only necessary to draw the attention of owners of fruit trees to the risk of killing these friends to avoid this source of loss. Spraying with various washes with the object of destroying green and black flies, caterpillars and the like can be safely and effectively carried out up to the time the blossoms begin to open, and again after the petals have fallen, without risk of danger to the pollen-carriers, and spraying should, therefore, be restricted to these times. Nothing is to be gained by spraying while the trees are in flower.

WORK IN THE GARDEN

BY this title is meant manual labour, which I find extremely difficult to theorise about when referring to owners of gardens. If I was asked for statistics, I should say that they were impossible to obtain, and would then immediately hazard a guess that 80 per cent. of garden owners who can afford labour loathe digging, 9.9 per cent. dig when they imagine that their bodies would be the better of the exercise, and .1 per cent. like it; but this one man in a thousand makes up for the other 99 and a bit per cent. in enthusiasm. There must be something in the actual process of digging which is thrilling because the real enthusiast will discuss the subject as other enthusiasts discuss golf or fishing. I frankly confess that I do not like digging for digging's sake. When it has to be done I do it, but then I stop. Not so the keen digger, who is always on the search for fresh ground to operate upon. Perhaps digging is a disease akin to that of chopping down trees. There is little doubt that some people are only happy with an axe in their hands.

I have a friend who is enthusiastic about manual labour in the garden. Naturally, he is a welcome visitor at my garden, and all kinds of difficult jobs are held over until his arrival. But he is not particular as to the kind of labour he undertakes. He is equally handy with a trowel, a spade or an axe, while his wife is the best raker of my acquaintance. My friend has a brother, whom it has not been my good fortune to meet, who appears to be happiest when digging a drain. He disappears after breakfast and pops up several fields away towards dinner-time. I am told that he is a banker, but his talents are obviously wasted in such surroundings, for diggers are born and not made.

It is peculiar how every gardener has some particular operation which he prefers above all others. There are dozens of them: the cult of the waterer, or the nettle cutter; the man who is happiest when cutting ivy off a tree; persons, male or female, who are nimble with their fingers and prefer pricking off seedlings; the weeder—this seems to be particularly popular among women—and, most peculiar of all, the individual who spends many happy hours picking green fly off roses.

I sincerely hope that such devotion is not materialistic, and that it is accomplished with the ultimate hope of seeing the garden in better condition for their labours, but I have serious doubts on the subject, for I believe that the individual would be miserable if there were no green fly to pick off his roses. There is a psychological effect of some actions which have little or nothing to do with the result of such actions.

No garden is so perfect that no labour has to be expended on it, and there is no glut of labour so complete that something does not remain to be done. It may not be digging, which, after all, is only a small but important section of garden labour; there is planting, pruning, sowing, pricking off, watering, sheltering and a thousand other tasks in the garden. Even by spending a few minutes on the least important of these tasks a garden owner comes more into contact with a subject which he may own but can never control, and it is by such actions that a better knowledge of a garden is acquired. Books and papers are excellent in their way, but they are of little use unless backed by a groundwork of experience, and a great deal of experience is to be gained by means of actual tasks in the garden, whether it be digging a drain or removing a greenfly, they all count as experience although varying in the amount of labour attached.

The man who can really judge correctly of the soil in his garden must have worked in it himself, for a fair-weather gardener is of little help to horticulture. Admiration and envy are pleasant in moderation, but true admiration is always backed by experience.

THE WILLOWS

AMONG hardy trees the willows occupy a very distinct and important position in the landscape. For the waterside and planting in damp situations where many trees would be unsatisfactory, the numerous species, varieties and hybrids are most valuable. They vary in height from tiny treasures of the rock garden, represented by the close-tufted growth of Salix serpyllifolia, a native of the Alps of Europe, and the smallest of the British willows, S. herbacea, a creeping shrub for a damp spot, to the tall and wide-spreading timber trees, SS. alba and cœrulea, 60ft. to 80ft. or even more in height.

Of the several valuable characteristics of willows, the most useful for waterside planting are those with pendulous or weeping branches and the bushes with showy catkins in spring. Distinct and pleasing throughout the year, it is, perhaps, in spring when the leaves are unfolding, that we see the willows on the flood tide of their beauty. Looking each day across the lake at Kew, watching the gradual clothing of the graceful branchlets with tender green leaves, provides a picture of beauty unsurpassed at any other season of the year. The best specimens represented are SS. alba, fragilis, cœrulea, viminalis, Salamoni and babylonica.

The best known and most popular of all cultivated willows for ornamental planting is S. babylonica, the Babylonian weeping willow. Growing as a specimen tree, it is wide-spreading up to 40ft. or 50ft. high, with a short trunk, numerous open-headed main branches, and long, slender, pendent branchlets. The Babylonian willow is an ideal waterside tree, with its weeping habit and love of moisture. The name S. babylonica is misleading, for this willow is a native of China, though it has for centuries been cultivated in North Africa, West Asia and Eastern Europe. Additional interest attached to this willow during the first half of the nineteenth century, from the fact that pilgrims to Napoleon's grave on St. Helena brought back twigs of a tree of this species, under which he was buried; hence the name of Napoleon's weeping willow, which is still in use.

THE GOLDEN WEEPING WILLOW BY THE POOL SIDE. THE BREAKING OF THIS TREE IS ONE OF THE FIRST SIGNS OF SPRING.

The white willow, Salix alba, as generally seen, is rather taller and more upstanding in habit, though with pendent twigs. It is the best known of our native willows, and has been freely planted in the Thames Valley and on the banks of its numerous tributaries. There are several forms of S. alba, the best known being S. cœrulea, the cricket-bat or blue willow, S. vitellina and S. regalis, by some authorities given as a variety of the white willow, the name var. argentea being used, which alludes to the silvery hue of the leaves, a particularly attractive feature with the branchlets swaying in a breeze.

S. cœrulea, the cricket-bat willow, is more upright in habit and forms a better trunk than most willows. The vigour of the tree is attributed to a hybrid origin, the reputed parents being S. alba and S. fragilis. S. cœrulea, in addition to the upright growth, is distinguished from the white willow in that the mature leaves are glabrous with a blue sheen beneath. The demand for the wood of this tree and the high prices paid for the best grade with which to make cricket bats has resulted in thousands of "sets" or young trees being planted, largely in the eastern counties, where willows do so well.

S. vitellina rivals S. babylonica in its elegant weeping branchlets for waterside planting, the golden yellow of the slender pendulous twigs being an additional attraction in winter. S. Salamoni is of hybrid origin, the parents being S. alba and S. babylonica. There are two beautiful specimens of this willow by the lakeside at Kew. In habit it is intermediate between the two parents, the main branches upright, the branchlets gracefully pendulous with the very distinct weeping character of S. babylonica.

S. elegantissima is another beautiful tree of hybrid origin, the parents in this case being S. fragilis and S. babylonica. Several species have a distinct value in the pleasure grounds apart from their actual association with water and boggy ground. Given deep, loamy ground with a leaning to the heavy rather than a sandy character, willows are useful either as lawn specimens or in the shrubbery border. S. magnifica was introduced by Mr. Wilson from western China in 1909. He describes it as a straggling bush or shrub up to 20ft. high. At first sight few would suggest that it was a willow bush, for it has large oval or obovate leaves 6ins. to 10ins. long and half as wide. S. gracilistyla is a native of Japan and Manchuria. It forms a bush of spreading habit, distinct in foliage and pleasing when in flower, with a red tint before the pollen ripens. S. incana is a close-growing bush up to 8ft. or 10ft. high and eventually as much in diameter. The narrow linear leaves, dark green above and white beneath, resemble those of the rosemary, hence it is not surprising to find this willow cultivated as S. rosmarinifolia, a name which properly belongs to a hybrid between SS. repens and viminalis.

S. Bockii, introduced from China by Mr. Wilson in 1908–9, is another very distinct plant, quite unlike any other cultivated species. It has small dark green leaves less than 1in. long, borne on low bushy plants 1ft. to 2ft. high. The catkins are very showy (especially those of the male), produced in autumn. It is of particular value for the bog garden.

Willows are so freely increased by leafless cuttings in late autumn and early winter, that any other method is seldom considered. To form a standard or half-standard, the Kilmarnock willow, S. Caprea pendula, is grafted on stems of a tree willow. S. magnifica does not grow freely with us at Kew, for which the light dry soil may be responsible. As an experiment we are trying budding and grafting on one or two of the free-growing kinds. S. Bockii is readily increased by layering. When seeds are collected, sow them without delay under moist conditions, as they soon lose their vitality.

Considering how readily they root from cuttings, it seems somewhat strange to find how necessary it is to give special attention to transplanting. Whenever possible, plant one or

Digitized by Google

two year old trees. As an alternative, insert the cuttings in the permanent positions. This saves any risk of transplanting, and under moist conditions practically every cutting will root. Cuttings several feet in length and made of wood three or four years old are frequently used to obtain quick results. These "sets," as they are termed, should be placed in their permanent positions. I have in mind a piece of swampy ground planted with sets of the cricket-bat willow 10ft. long, which two years after planting looked as if they had stood for at least five years.

Of the several families of catkin-bearing trees and shrubs, the alders, the birches, the poplars, the hazel nuts and the willows, none surpasses the last-named. In point of variety and numbers they are unequalled. We are all familiar with the showy male catkins of the "palm" or goat willow, Salix Caprea. Though a common occupant of many hedgerows, this species is deserving of much more attention from planters.

In most species of salix the male and female catkins are borne on separate trees. While both are attractive in flower, the male is the more ornamental because of its golden-tipped anthers. There is, however, much to admire and interest the lover of nature in a bush or tree freely clothed with the silvery hue of the female catkins.

Looking into the life history of willows, when we consider that the male and female organs are generally produced on different plants, is it surprising that hybrids rival the species in numbers? They are generally wind-pollinated. During the glorious Easter weather, walking through the Kew collection several times I was surprised to see how busy the humble and hive bees were on the catkins. The amount of cross-pollination that was taking place can very well be imagined. Perhaps it is fortunate that frosts injure so many of the catkins, as, in view of the large number of female catkins, few mature good seeds.

The collection of salix at Kew contains something like two hundred species, varieties and hybrids. From such a wealth of material it is not easy to recommend a limited selection for planting. While admitting that many are of no particular merit outside botanic gardens and arboretum collections, it would be quite easy to name fifty of outstanding merit and of value to planters.

Ten willows to plant as specimen trees by the waterside and in damp positions are: SS. alba, babylonica, cœrulea, daphnoides, pendulina (elegantissima), fragilis and var. Basfordiana, Salamoni, viridis and vitellina.

A BEAUTIFUL WEEPING WILLOW OVERHANGING A LILY POOL.

Selection of willows with attractive catkins: SS. aurita × phylicifolia, Bockii, Caprea, Caprea × lanata, cinerea, cinerea var. tricolor, daphnoides var. acutifolia, gracilistyla, cordata var. glaucophylla (female), livida × repens, Medemii, Nicholsonii var. purpurea (female), Smithiana and virgata.

In wet places and by the waterside several willows are extensively planted for the winter effect of the coloured bark. The best are the golden-barked willow, S. vitellina, the cardinal willow, var. britzensis (red) and daphnoides, the violet willow.

A number of dwarf willows are useful and interesting plants for the edges of rock pools and damp spots in the rock garden. When planting on slopes it is an advantage to use stones freely, for, in addition to holding the soil, the roots revel in the moisture conserved by the rock stones. Of the dwarf species those usually favoured for the alpine or rock garden include S. Arbuscula, a shrub of spreading habit, useful to trail over boulders and ledges, a native of Europe and Siberia; S. herbacea, a British species, an interesting little shrub of tufted habit 2ins. or 3ins. high, catkins up to ½in. long; S. Lapponum, the Lapland willow, of spreading habit, under cultivation sometimes up to 3ft. or more in height, but can be readily kept within limits by annual pruning. When space permits in large rock gardens it is worth while placing a few large stones on the spreading branches. S. Myrsinites is one of the prettiest alpine willows in flower.

Apart from Public Gardens, there are picturesque willows to be seen in the gardens at Aldenham and Gravetye.

EARLY-FLOWERING CHRYSANTHEMUMS

ONE of the chief reasons why many amateurs do not obtain the best results from these easily grown flowers is inadequate soil preparation. The very fact that the early-flowering chrysanthemum is an easy plant to deal with leads many to believe that a good crop of bloom can be expected with little or no special culture. The folly of this assumption can easily be proved by watching the progress of plants put out in soil that rapidly loses its moisture during the summer season and those planted on a well prepared site. During the drought the latter suffer no check.

The ground should be dug to a depth of about 2ft. and a liberal supply of well rotted animal manure forked into the lower spit to provide the necessary humus and a cool root run. If the soil is of a light nature, use cow manure, if obtainable; but where this is scarce Wakeley's hop manure is an effective substitute. On heavy land strawy manure, wood ashes or leaf-mould will be found beneficial.

As soon as the risk of frosts is over—usually in May—planting out may be commenced. The chrysanthemum needs a long season of growth, so that if planting is delayed until June the plants have not a fair chance to mature. If cuttings have already been struck from stock in hand, see that these are well hardened off before planting out. Frame lights may be left off during the day at first, afterwards being dispensed with altogether as the nights become warmer. Usually, plants that are purchased from a reliable firm are properly hardened off when received; but if they are to be planted in a bleak situation it is a good plan to pot them up for a short time till the weather becomes favourable, or, if this is not possible, at least protect them from the cold winds by twiggy growths.

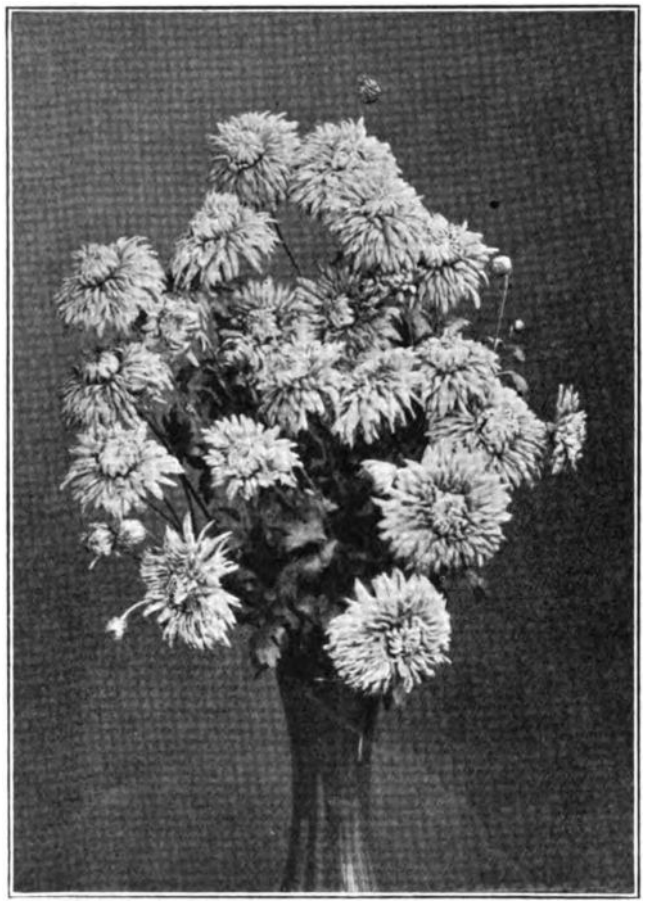
When planting, tread them in firmly so that the roots have a good grip of the soil, when new root action is promoted. A stake should be placed against each, and one or two initial ties made so that the young plant has no chance of being damaged by wind. Allow from 2½ft. to 3ft. between each plant. Some of the free-flowering varieties have a bushy habit, and overcrowding spoils their effectiveness and hinders development.

The hot, dry period of June and July is the most critical time. Water should be given when necessary, and a good soaking once a week in the evening is better than light sprinklings that only tend to make the surface soil become "baked" and never reach the roots. If growth is retarded, a quick-acting fertiliser scattered around the plants in showery weather or watered in will provide a stimulus; but care should be taken not to give an over-dose, or the growth will become coarse and leaf production will take place at the expense of flowers. In a continued spell of drought a surface mulch is beneficial in conserving moisture. Short animal manure can be buried just beneath the surface soil around the plants, or lawn clippings can be substituted for this purpose, if desired.

The leaf-mining maggot may make its appearance about this time. A good remedy is to water the foliage with soot water, which makes it bitter, while the plant at the same time receives extra nutriment.

Earwigs and aphis are often very prevalent during July. The former can be picked off and destroyed, or they may be easily caught by suspending a half-open match-box filled with tissue paper among the foliage. This provides a retreat for the pests. The match-boxes should be examined at regular intervals, and if this is done systematically the pests can be kept in check.

Aphis is more readily destroyed. A few regular applications of an insecticide, or a mixture of soft soap and quassia such as is used for spraying roses, will be found effective. The persistent use of the insecticide, say for four or five successive days, is the chief point to remember when destroying aphis on any outdoor plant. If intermittent applications are given the pest is never properly kept in check.



A NEW EARLY-FLOWERING VARIETY, ALEX. A. McALPINE.
The colour is rich golden orange, shaded pale bronze.

Besides the all-important decision regarding the choice of pleasing colours, the type of flower should be taken into consideration. There are very early types that open in August, late August and early September varieties, and those that do not bloom until late in the season and sometimes require protection from the mists and frosts of autumn. Many of the latter kind are admirable for lifting if a greenhouse is available. By this means the trouble of growing them in pots during the summer, when much attention is required in watering, can be avoided. The blooms which open from lifted plants are usually of better quality and more refined in colouring than the earlier sorts.

Single varieties are now very popular, and these are useful and pretty for decoration when grown in sprays.

Although many of the newer varieties have proved that much progress has been made by the hybridist during recent years, there is still a large number of the older kinds that are indispensable. Most of the old favourites are very free-flowering, commencing in late August and continuing throughout September and October if the weather is favourable, and a large proportion of them will survive the winter in almost any locality. In the spring they may be either undisturbed for the second season, or the plants may be divided.

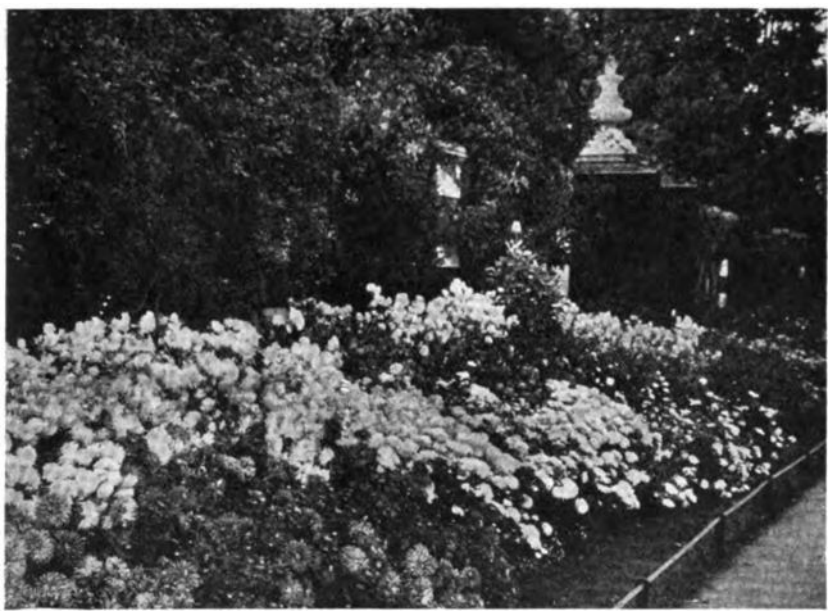
I will deal with some well known groups of the earliest-flowering kinds. All these can be relied upon to bloom before the first frosts appear, so that they may be termed true border varieties.

The "Polly" type includes the original parent of that name, which gives deep orange flowers with amber shadings,

Digitized by Google

and its sports, Abercorn Beauty, Crimson Polly, Golden Polly and Florrie Wilkinson. Abercorn Beauty is a rich bronze with reflexing florets, and Florrie Wilkinson is a golden yellow. All these commence flowering very early, so that they should be planted as soon as possible to enable them to get a good start and they require liberal treatment and, if possible, frequent mulchings during the hot weather.

The " Masse " family is probably the most widely grown type, and its ubiquity is explained by the fact that it will thrive in any district and in any kind of soil. The chief characteristic of this type is the enormous quantity of bloom produced. When compared individually with the later-flowering " earlies," the flowers are somewhat *négligé*, and some of the colours are not so pleasing; but to the town gardener, who often finds the better class varieties difficult to grow, the " Masse " family are a great boon, and it is small wonder that almost every front garden or allotment is bright with them in early autumn. Improved M. Masse is a large rosy lilac; Horace Martin and Elstob Yellow are two good deep yellows, especially the latter; George Bowness is crushed strawberry; Mrs. J. Mason, deep salmon rose with a buff reverse; Robbie Burns, cerise; and White Masse is a creamy white. John McAlpine is a newer



BORDER CHRYSANTHEMUMS AT HAMPTON COURT.

variety of merit that seems to be related to the " Masse " family. It gives blooms of better quality than the older sorts, and the colour is a pleasing blend of rose pink and apricot. I find that this variety winters quite as well as the other kinds mentioned, and it provides a large number of cuttings.

The " Perrier " group is another floriferous type. It is also very easy to grow. Mme. Casimer Perrier, cream and pink; Cream Perrier; and Mrs. A. Willis, yellow shaded red, are three varieties that will appeal to town and suburban gardeners.

Goacher's Crimson and its " sports " provide another small class that is noted for a better built bloom and broader petal than we find in the " Masse " family. The rich colouring of Goacher's Crimson gives a kind of autumn touch to a room. Bronze Goacher's is a reddish bronze, and Golden Goacher's is aptly described in the name. Mrs. J. Fielding also belongs to this group, and its colours, chestnut red and gold, are very pleasing.

Among white varieties, Roi des Blancs and its companion, Reine des Blancs, are two good early sorts that attain a moderate height and which are useful for cutting in sprays. Pluie d'Argent is a good dwarf variety that is always a mass of bloom.

I have found nothing better for decorative work than September White, which I have grown since its introduction a few years ago. In an early season with fine weather in September it can be cut quite clean out of doors even in the North, but last year it had to be lifted. It is an early " sport " from the old variety, M. Julian Valat, and the blooms have broad incurving petals of fine substance.

Framfield White is a different type. It has rather a stiff habit and if grown naturally the crown bud develops a large bloom which opens earlier than the others, which are produced on short sprays up the main stem. This variety is largely used for wreath work, where length of stem is not an important factor. If grown for decorative work it should be disbudded.

Sanctity has some admirers, but I do not think it is as fine as September White. Lichfield Early White is a promising new variety, the flowers of which are carried on long wiry stems. It will bloom in September in a favourable season, and the plant grows about 3ft. high.

Among favourite standard varieties, Carrie is a good canary yellow of very bushy habit, and Leslie is a well known and popular buttercup yellow that is very free flowering. Nina Blick is a reddish bronze that still remains a great favourite in spite of the fact that it is an old variety. Dick Barnes is newer and is a deep, rich Burgundy crimson. I find that this variety resists the damp and dews better than the looser-built flowers. It is a vigorous grower and very free. Normandie is a pretty flesh pink that gives lovely sprays; and Silver Lining, a white frosted pink from the well known variety, Miss G. K. Thorpe, is very delicate in its dainty colouring. Lichfield Purple and Lichfield Pink are two reliable varieties in their respective colours. Those who like mauve pink cannot find a better early than Hector. Harry Thorpe is a flower of similar type, but the habit is better. Its colour is deep yellow with a suffusion of fawn. Ena Thorpe has flesh-pink blooms of incurving form and waxy petals with a silvery reverse. Nellie Thorpe is a beautiful shade of salmon with peach suffusion on a yellow ground. It recently gave a red sport that is known as Crimson Nellie Thorpe. Mrs. A. W. Thorpe is a September variety of a pretty coral shade with salmon suffusion. All these are high-class varieties.

This season sees the advent of many fine new introductions, of which Alex. A. McAlpine, Charlotte Harley, Jessie McAlpine, Innocence, Jessie T. Yuill, Cranfordia Supreme, Australian Gold, Fireflare, Purple Flag, Royal Salute, Saracen, Shirley Blush, Shirley Rose, Shirley Sunset, Robert Garrett and Salmon Profusion are among the choicest.

Alex. A. McAlpine is a seedling from Goldfinch and White Masse. The colour is a rich golden orange shaded with pale bronze. It has a stiffer stem than the Masse family and is not so straggly as Goldfinch. It is a very prolific bloomer and the flowers do not give the bad centre of the parent.

Charlotte Harley is a brilliant scarlet-crimson with gold reverse, probably the brightest coloured of all early varieties. It has long reflexing petals which build up massive flowers when disbudded, while it is also good in sprays.

Jessie McAlpine will, perhaps, prove to be the best of this trio from Tollcross. Outdoors it is a refined shade of pale shell pink, under glass pure white. It gives a very large bloom even if not disbudded, and the stems are usually

Digitized by Google

2ft. long. It is a flower of the same type as Hector, but with the strong growth of Countess.

Royal Salute is a bright terra-cotta with scarlet suffusion. The blooms are carried on strong stems and in fine sprays, making it a desirable decorative variety. Shirley Sunset combines many of the sunset hues in its almost indescribable colourings. This is also a fine decorative variety and blooms early in the season.

NORMAN LAMBERT.

SMALL GARDENS IN LONDON

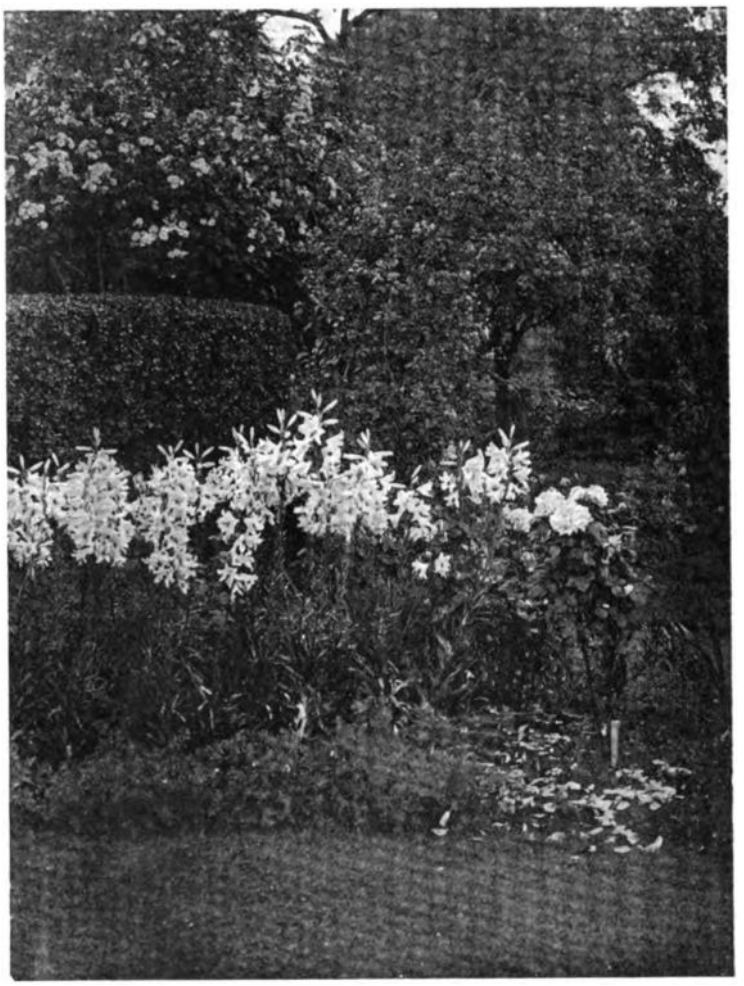
BY MELESINA SETON CHRISTOPHER.

IT is only of late years that town-dwellers apparently have awakened to the fact that, given a very limited amount of Mother Earth, miracles may yet ensue. The small spaces at the back of many London houses are now being turned to good account, and it is becoming more and more usual to find, not merely formal beds of geraniums and marguerites, and other productions of the florist, but little borders of herbaceous plants and flowering shrubs, and walls clothed with clematis, jasmine and vine. Altogether pleasant little oases among the surrounding bricks and mortar.

On becoming possessed of a small garden, should it have been neglected, it is well to call in an experienced gardener and to provide good soil wherever flowers are desired. Probably it will be necessary to dig to a depth of 2ft., or possibly to trench the whole of the ground where planting is to be done. This may seem laborious, but results repay the work. What is added to the soil depends on its condition. Slaked lime at the rate of 2 oz. to a square yard is wholesome where the soil has become vitiated, and it acts as a liberator to the good things that it is prudent to add before beginning the more ornamental part of the garden.

Grass is somewhat hopeless to grow in confined spaces in London, and either flat paving stones or gravel are to be preferred. The former can be made most attractive with small flowers planted in between the flags, while gravel adds a warm tone. If a rock garden is contemplated, it should be built with care, not in the shade nor under trees, but given a sunny spot. Some of the stones should be placed horizontally to prevent too rapid drainage, and others perpendicularly, allowing for pockets of good soil between. Many little plants, such as alyssum and aubrietia, thrift, dwarf veronica, stonecrop and Saxifraga umbrosa, together with creeping Jenny and small campanulas, will be happy there. In the spring, crocuses, snowdrops and primroses will all help to keep the rockery bright.

Autumn is the best time for planting flowering shrubs and creepers to cover walls, and spring will bring into blossom the starry yellow forsythia and the pink almond blossom; later on ribes will do well. Weigelas make sturdy growth in London, and their rosy flowers are more interesting than the greens of privet and laurel, which are rather ground devourers. In the summer, clematis (Jackmanni and montana) generally do well, and polygonum can be trusted to cover an ugly wall quickly. Then there are, of course, the larger creepers, Ampelopsis Veitchii and Virginian, which practically never fail. Jasmines, lilacs, rhododendrons and laburnums are all worth trying, though there will always be great competition for the sunniest spot in the back garden, for few things enjoy the shade that falls all too early on most built-in spaces. For this reason it is sometimes advisable to raise the flower-beds, edging them with a little wall of stone tiles, as they then make more show and can by this means detain the great life-giver, the sun, a little longer. Even lilies of the valley, which will thrive in London, like as much sunshine there as can be given them.



THE FRAGRANT MADONNA LILIES SHOULD BE GROWN IN EVERY GARDEN.

All bulbs planted out of doors in September and October will, as a rule, give good value, and they can be put freely even under trees, as the blooming time will be over before the leaves come to overshadow them. Madonna lilies can easily be a great success, and are one of the few flowers capable of filling even a London garden with delicious scent. They are best planted in August in groups of three or four, 1ft. apart and about 4ins. deep. Orange lilies (Lilium croceum) are also effective and easily cultivated. From the early gold and purple of the crocus to the gorgeous late-flowering tulips no town garden need lack colour from March onwards, and even the hyacinths and tulips grown in the house can be replanted out of doors, and will give good account of themselves the next spring.

For permanent plants, irises of all sorts, Japanese anemones and Michaelmas daisies are all good stayers, and carnations make no objection to London, the little Allwoodii being especially well disposed. Seeds, with the exception of Virginian stock (which can be obtained in several shades) seem to come to an untimely end in most town gardens, neither do small plants, such as wallflowers, survive happily through the winter. It is, therefore, best in early spring to buy little sturdy plants of wallflower and later on verbena, ageratum, delphiniums, sweet williams and antirrhinums when all the perils of infancy are over. Fuchsias and pelargoniums also do well, while geraniums and marguerites are not altogether to be despised. The tobacco plant, both crimson and white, can often be relied on to grow and flower, even in shady places, but nasturtiums and sweet peas are rather fickle and uncertain in the confines of a back garden.

Cats, sparrows and slugs are among some of the worst enemies of London gardens. The inroads of adjacent cats

Digitized by Google

can, however, be circumvented by protecting the places of ingress with fisherman's netting. It is more efficacious than wire barriers, as the cats are afraid to put the weight of their bodies on it and also of entangling their feet.

Sparrows are always with us, but their misdeeds may be minimised if a deep saucer of fresh water is provided for them. They often attack the young buds of trees and crocus flower blossoms, for the succulent moisture they find there, and water satisfies in part this need, as well as keeping them occupied bathing. Slugs are the meanest of foes, for they do their work stealthily after dark. Luckily, they do not usually appear until late in the season. They can generally only be dealt with by taking a lantern in the evening and hand-picking them off the leaves. If later in the year they are allowed to do their evil work of stripping the plants, they can be finally destroyed *en masse* by a liberal liming of the garden in the autumn.

Plants do not as a rule spread much in town gardens, so they can be put fairly close together and extra sustenance be given them by means of one of the many patent fertilisers. These should, however, be dealt out sparingly with an old teaspoon in the dry form and watered into the roots, but only when the flower-buds are showing, as otherwise the treatment tends to make leaf. It is fatal to hope to revive a sickly plant by means of artificial stimulants.

Gardening in towns may have many drawbacks and disappointments, but its triumphs are all the greater in proportion. In a large or small space plants are like children and need constant loving care and attention, but this is one of their charms. One day it may be a good douse of water at the roots and another a small support against a high wind. Then there is the perpetual demand that their leaves and stems should be kept as free as possible from dust and dirt. They are even grateful for the application occasionally of a nailbrush and a little soft soap and warm water. Most important of all is that the ground at their feet be constantly and carefully forked, and opened to such light and air as is available.

In return for all this attention even the efforts put forth by London plants and flowers will bring joy and satisfaction at what can, by co-operation with Nature, be brought out in beauty and blossom from the brown earth.

PROTECTING FRUIT BLOSSOM AGAINST FROST AND BIRDS

THE weather conditions this year, so far, are not quite normal. Frosts have been severe and frequent; a few days are mild and the weather, generally, promising, then frost comes again suddenly, and this condition obtains about one month later than is usual. With regard to fruit buds their development is also three weeks or a month later, but the milder intervals have the effect of causing the buds to soften and swell and in this state they are very tempting to the birds.

The cultivator should be quite clear as to which of the two evils he is preparing to protect his buds and blossom against—frosts or birds, chiefly. If against the former a partial covering of the branches will be sufficient as frosts strike downwards and, therefore, the screen against them should be above the trees and deeper on the north to south-east sides, more open on the north-west and south-west.

If against birds, then the whole of the branches should be enclosed, but with a sufficiently open screen to admit bees to the blossom while excluding the birds.

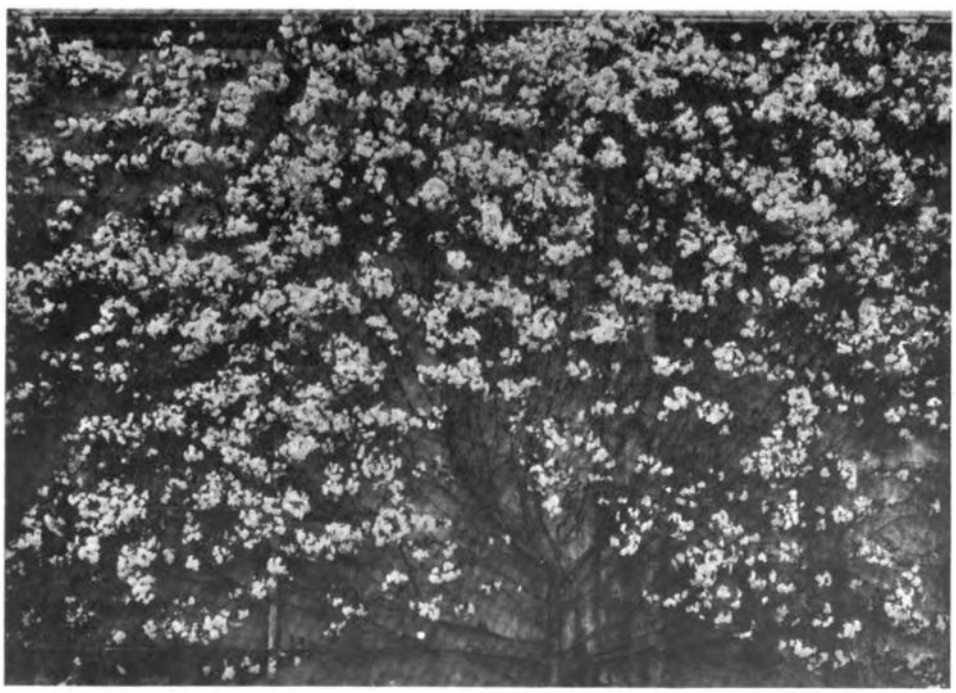
Moisture renders a plant or a mass of flowers susceptible to cold and the damper the surface is, the more severely will the frosts affect them. Although a branch may be cold, if it is dry, the damage from frost will not be as severe.

Not only should the flowers be kept dry, but the protecting material also. Where there is air movement there is less frost; where the air is confined and moist there is more frost.

Standard, half-standard, bush and pyramidal trees in the open quarters are not liable to be frozen to the same extent as espalier-trained trees with their branches fastened rigidly to wires or stakes.

MATERIALS TO USE.—There are certain forms of trees that require special protecting material, so, whether they are trained on walls or fences or growing in the open quarters, the most suitable material should be provided. Scrim is excellent for the purpose, herring nets can be used where scrim or tiffany cannot; fir branches, obtainable in some districts, are very effectual; 9in. boards are useful where there are low walls; mats are, too; and even black thread can be used with good results against birds.

HOW TO FIX THE FROST SCREENS.—I will presume that the cultivator has a wall of trees—peaches, pears, plums or cherries—or even a single specimen on a wall to guard against frosts. The tiffany or herring net is the best to use in such case. Walls with wide copings, the edges protecting on both sides several inches, are the best to which a length of scrim can be fixed, as the latter can be rolled up and kept dry under the edge of the coping stones or tiles. The readiest way is firmly to fasten a strong galvanised wire to staples in the wall about 4ins. below the coping. The width of scrim for a wall 10ft. high should be half its height. On one side, at intervals of 2ft., strong twine should be tied, with two loose ends left 6ins. long, by this means the scrim can be made secure to the wire under the coping. For a wall 6ft. high, scrim 2ft. 6ins. wide will do nicely. In the case of a high wall strong pegs, about 18ins. long should be driven, in a slanting position, with points to the wall, into the ground 4ft. distant from the wall and 6ft. apart. In the case of lower walls the pegs should be driven into the ground 3ft. distant from the foot of the wall. Strong wire should be fastened to the



MORELLO CHERRIES ON A WALL SHOULD BE PROTECTED BY HERRING NETS OR TIFFANY.

Digitized by Google

wire under the coping stones and also to the pegs in the ground. The angle of these wires will be very sharp, but just suitable for bearing the scrim when the latter is unrolled and let down. On the lower side of the length of scrim, and just opposite to each ground peg, strong twine should be fastened and made secure to each peg, respectively. Herring nets, single, doubled or trebled, may be fixed over wall trees in a similar way. One should remember that it is necessary to make all such coverings quite secure against strong winds so that there will not be any danger of loose parts being blown against the blossom and doing it a lot of harm.

FIR BRANCHES.—These form a very simple but effective screen against frost and, to a certain extent, against birds, as where buds are not directly visible to their eyes birds will not seek for them. The same principle applies in the case of fir branches as with scrim, but the manner of fixing is different. Fan-shaped branches should be selected, one measuring 3ft. by 2ft., or 2ft. 6ins. would be sufficient to protect 9 sq. ft. of wall space. The stem end of the fir branch is nailed, or otherwise made fast, to the wall near the top, the stem being uppermost the fan spreads downwards and should be kept out from the wall and the blossom by means of forked sticks cut to the right length. Strands of wire or string passed over the branches, the ends made fast to the wall, will keep the branches in position. No branches need be fastened to the wall lower than 4ft. from the ground.

In the case of cordon fruit trees in the open border, espaliers or other specimens, fir branches may be nailed on the top of the supporting stakes or to special stakes driven into the ground at convenient intervals. I have tied fir branches to the stems of branches of bush fruit trees in different positions with very good effect. Of course, the fir branches are fixtures for the time being and they should not be used to form a too dense screen.

ESPALIER-TRAINED PEAR TREES MAY EASILY BE PROTECTED AGAINST BIRDS AND FROST.

SMALL PLANTATIONS OF FRUIT TREES.—To protect a small, or medium-sized bush fruit tree from damage by frosts and birds, the best way is to fix stakes into the ground, with two top cross laths fastened to the upright stakes. Several strands of string or twine or wire passed round and tied to the sides of the stakes will form a suitable framework, effective and cheap, to bear the herring nets thrown over and tied to the stakes near the ground. This principle applies in the case of plantations of small specimens of fruit trees. It is not wise to use tiffany or any similar close-woven material entirely to cover fruit trees in the open quarters. It may be fixed as a top covering, temporarily, with nets round the sides in the case of single specimens of fruit trees, but for plantations the most economical plan is to place the upright stakes conveniently and high enough to bear cross wires over the trees so that the nets, placed on these cross wires, will not sag down on to the branches of the trees. Fine-meshed wire netting should be placed at the base all round the enclosure and against the outside rows of upright stakes. The herring nets, single or doubled, should be fastened to the wire netting and not brought into contact with the soil; then they will not rot readily and will be available for use for several years.

BLACK THREAD, judiciously applied in the case of small bush fruits and where there are espalier trees, is a wonderfully effective protection against birds. I have fixed the strands of thread, carefully passing them along the branches and zig-zagging them over bunches of buds, making the thread fast to the most prominent or projecting parts and found that all trees and bushes so treated were left severely alone by the birds.

GEORGE GARNER.

EAST LOTHIAN STOCKS

THE border, where these are planted, is rich with promise, and spikes of bud are plentiful. But while we are congratulating ourselves upon these, do not let us overlook the preparations that must be made now to ensure a repetition of the fragrant show next year. Before last season's plants have expanded their first buds, our young plants ought to be through the soil and that means that sowing must be done now. A long period of slow, steady growth is the real secret of success and when one remembers that this means a display of the huge spikes all through June, July and August, it must be admitted that it is certainly a thing to strive for.

A partially shaded corner is the best place in which to sow the seeds. Sow thinly and, at the earliest possible moment the plants can be handled thin out so that they stand a couple of inches apart. Care should be taken all through the summer to see that they never suffer from lack of water and, as soon as strong enough, it pays to transfer each plant to a single pot. Use a light, moderately rich soil for this and take care to make it thoroughly firm, so that the growth will be of the short and stocky order rather than long jointed and sappy. otherwise they will not pass through the winter well.

Potting completed, the best place for the plants is an open, sunny position outdoors, where they can be sunk to the rims in an ash bed. Here they will demand but little attention, save an occasional watering in dry spells, until November, but then the protection of a cold frame should be given. Stand the plants close together and water sparingly, so that, when frosts occur, they will be dry at night. Under prolonged spells of severe frost an extra mat covering should be placed on the frame, although one should be careful never to coddle the plants. Undue covering up or lack of air merely encourages undesirable growth that is useless for flowering; and, for long periods in any ordinary winter, it should be possible to leave the frames open several notches both day and night, although care should be taken that these are not propped so that rain can drive in and soak the pots near the edge.

Early in the following April the plants should be placed in their permanent quarters and, for these, a sunny sheltered bed or border should be chosen, of which the soil has been well enriched with rotted manure. Well water the pots the day before planting and press each plant into the earth rather firmly and see that, from this date onwards, the soil is always kept thoroughly moist; drought is fatal to a fine display of flower. Where used to fill a bed in a prominent position, a few plants should be kept in reserve and grown on in larger pots in the open air. These come in very useful for filling in, where singles appear among the flower beds.

H. W. CANNING-WRIGHT.

A PLANT-HUNTING HOLIDAY AT MURREN

AT the risk of lacking originality in writing these notes, I venture to place before readers a short account of the alpine plants to be found around Mürren in the Oberland.

I read with great pleasure the excellent account given by Mr. Lofthouse, in THE GARDEN of December 1923, (pages 641, 648, and 661) of a similar holiday made in the Pass of Mont Cenis, and the enthusiastic reception this received has led me to describe a similar holiday, which was, however, taken in a district which can be reached much more easily and comfortably by anybody who does not care to make long, arduous walks, and in a district, also, which is inclined to be avoided by plant-hunters, from the fact that it is dubbed a typical tourist resort to which it is no use going if one wishes to obtain the choicer alpine plants.

To begin, it is very convenient that the hey-day of alpine plant life is at its height *between* the tourist seasons. My holiday extended from June 26th to July 16th, and during that time the hotels were all practically empty, and the holiday rush crowds on the railways had hardly commenced.

Mürren is situated at 5,415ft. above the sea level. It is reached by railway, and, consequently, one starts walks in search of plants without the fatiguing climbs in the grilling heat of the sub-alpine regions. The walks are many and various, and the views of the mountains, Jungfrau, etc., are wonderful. Around the hotel at this time all the tall-growing flowers were converting the hay-fields into a glorious mosaic of colour. The chief of these were: Campanula rhomboidalis, Polygonum Bistorta, Centaurea alpina, Phyteuma betonicæfolium, P. spicatum, Astrantia major, Geranium sylvaticum, Chrysanthemum Leucanthemum, etc.

A short climb brings one above the hay-fields to regions where the dwarfer flowers are having their day before the hay grows up and protects them from the scorching sun. Here one finds Oxytropis montana, Geum montanum, Myosotis alpestris, Gentiana acaulis in several varieties, Campanula barbata, Chrysanthemum alpinum, Helianthemum alpestre, Viola calcarata in all manner of shapes and in colours from purple to yellow. On the huge boulders which dot the slopes and on very stony parts are masses of Linaria alpina, Potentilla alpestris, Globularia cordifolia and G. nudicaulis, all flowering so amazingly when compared with the reluctance they show in our English gardens; also Erinus alpinus, Sedum alpestre, Gypsophila repens, Saxifraga Aizoon and dwarf sempervivums.

In the moister parts are masses of Ranunculus aconitifolius and Trollius europæus, while the big heads of Veratrum nigrum are poking up.

To take the most interesting walks in a little more detail, those to Blumenthal and Schilt-thal are, perhaps, the most delightful. The former, as one rose above the hay meadows, presented a seething mass of Anemone alpina and A. sulphurea equally mixed, which rather counteracts the theory that A. alpina lives on limestone and A. sulphurea on granite. Among these were the purple heads of Orchis globosa, Nigritella angustifolia and Hedysarum obscurum. At the foot of the slope were large areas of Gentiana verna growing happily intermingled with Androsace Chamæjasme. Here and there were hummocks clothed with Lonicera alpigena, forming a home for Thalictrum aquilegifolium and Campanula barbata. In the moister parts, notably in the banks and rocks of the foaming streams, were Primula farinosa, Pinguicula vulgaris, Dryas octopetala, Viola biflora, Bellidastrum Michelii,

A MOUNTAIN STREAM, THE HOME OF SAXIFRAGA AIZOIDES.

and Saxifragas aizoides, stellaris, rotundifolia and cuneifolia.

The district of Schilt-thal presents quite a different variety of flowers. While approaching it through damp rocky scrub, the stems of Gentiana asclepiadea were seen poking through the carpet of pinguiculas, Primula farinosa and Orchis globosa. On reaching the entrance of the valley the grass in the distance appeared one mass of pink, which turned out to be millions of Primula farinosa in every conceivable shade, intermingled with pedicularis and Gentiana verna. The effect was wonderful and the site very remarkable. The hillside was one huge swamp, into which many channels had been cut for drainage. These channels were only 1ft. deep and were floored with solid rock; the section of the soil showed it to be nothing but an oozing spongy mass of peat. Hence these flowers were revelling in blazing sun and copious running water, but—and here is the lesson—the soil was not composed of stone chips, of which we are so often advised to make our special beds for alpines, with water flowing beneath, but pure peat with grass roots everywhere to drain the surface. Having seen this, I have constructed part of my rock garden on the same principle—rocks 1ft. deep covered with sandy peat, on which I have sown a dwarf grass and in which P. farinosa, G. verna and soldanellas I brought home are flourishing and are now showing more flower heads than they ever do in more arid situations. Of course, it is most essential that such a bed—or *tourbière*, as M. Correvon calls this structure—should be kept bone dry by means of a pane of glass in our damp winter days. On passing this delightful spot one came upon huge clumps of Gentiana bavarica growing in soaking grit by the stream-sides, and a little farther on Anemone narcissiflora and Primula elatior. On the huge boulders, and nearly always on their shady side, were large colonies of Primula hirsuta, glowing like rubies in the distance, among the white stars of Ranunculus alpestris. Many hummocks afforded homes for the prostrate willows—Salix reticulata and S. retusa—out of which dotted the shoots of Daphne Mezereum and the white D. alpina, both with a delicious fragrance. On going a little farther and higher, to where the snows were just receding and the grass not yet grown, one found the ground covered with Soldanella alpina and Crocus vernus, the flowers of which were even coming into bloom after piercing the edges of the snow patches. A photograph taken on this occasion was reproduced in THE GARDEN of February 2nd last (page 62).

Another delightful walk was down through the village of Gimmenwald. Here the path branches, one going through the woody valley of Sefinenthal, rather uninteresting from a flower-hunter's point of view, except for a few plants of Anthericum Liliastrum. The other path—which was built up with rocky walls in the crevices of which were the dainty fronds of Polypodium calcareum, in the blazing sunshine with no visible means of obtaining moisture—takes one down through rocky woods to the Lauterbrunnen valley near Stechelberg. This was a glorious walk. In the steep rocky woods were masses of Lilium Martagon and Pyrola rotundifolia, both extremely difficult to get up whole. On the edges of the wood were Digitalis lutea and 3ft. spires of Gentiana lutea. When down in the Lauterbrunnen valley a visit was made to the Trummelbach Falls, where the waters from the Jungfrau glaciers hurl themselves down through deep chasms in the cliff. Near here were found Saxifraga cæsia, growing in the cracks of the barren cliffs, and Anthericum ramosum growing in the gritty debris. Below Lauterbrunnen the undergrowth of the fir trees was thick with the rosy heads of Cephalanthera

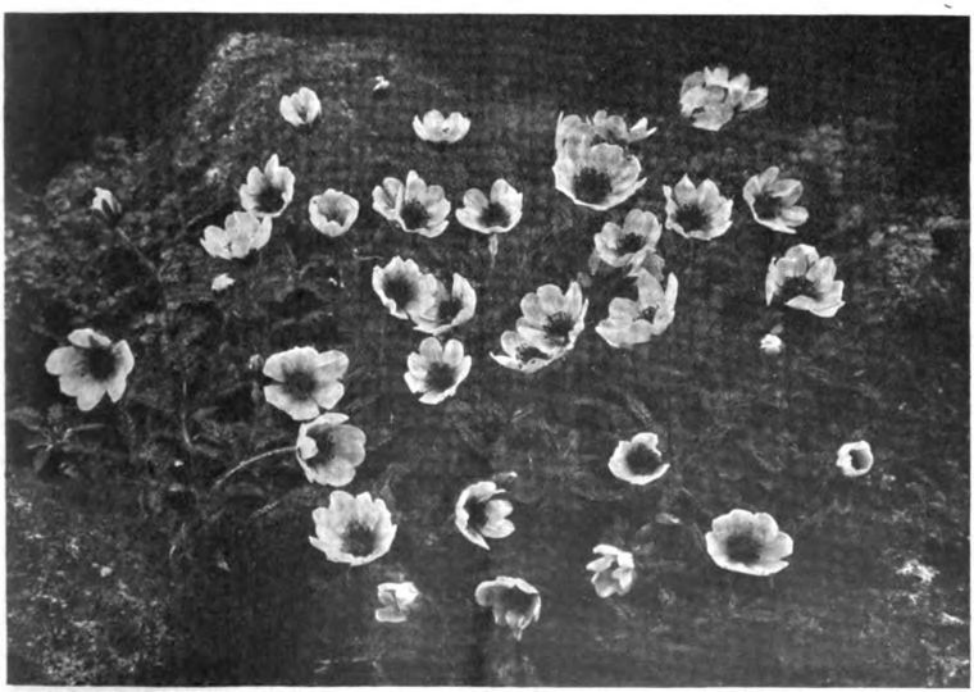
Digitized by Google

rubra, and in the deeper shade were large clumps of Polypodium Phegopteris among other ferns. The grilling walk up to Mürren only produced Pyrola secundiflora by way of new finds, growing in the coarse, shady grass.

From Lauterbrunnen one can take the railway up to Scheidegg and the Jungfraujoch. On the downward journey a walk was taken from the station at Eiger Glacier to that at Wengen Alp. On leaving the first a large patch of ground was completely covered with the silky nodding heads of Anemone vernalis, and on nearing Wengen Alp the flowers of Gentiana acaulis and Viola calcarata were far more attractive than those on the hillsides around Mürren.

To return to Mürren, which was always the starting point, it remains to describe the walks in an easterly direction. The first and nearest is through the fir woods to Winteregg. Beneath the trees the whole ground was covered with the leaves of Anemone Hepatica, now, however, out of flower. Several plants were brought home at random, which are now in flower and showing colours varying from deep blue to mauve. On passing the Winteregg cowsheds the ground became soft friable peat, and here on every side the flowers of Arnica montana and Trifolium alpinum were just opening, peering up around the scrub of prostrate Juniperus communis alpina, arctostaphylos and Polygala Chamæbuxus. Over the buried rocks were rambling Antennaria dioica, Homogyne alpina (syn. Petasites alpinus). Near the stream, on a piece of ground which was now baked as hard as bricks but was obviously quite recently a swamp, were the little yellow stars of Gagea lutea; and on following the stream higher up among piled-up heaps of debris one found Hutchinsia brevicaulis and Thlaspi rotundifolia, probably washed down from higher places. Parnassia alpina was poking up its leaves, although not yet in flower, and the little white Pinguicula alpina with sheets of Saxifraga oppositifolia were everywhere mixed with soldanellas, and Gentianas bavarica and verna, the leaves of the latter being amazingly minute when compared with those found at lower elevations. On turning towards the hillside on the left, one came upon a wonderful sight. The slope appeared to be grassland, but on near approach it disclosed itself as large flat slabs of rock almost completely covered with thin turf. Over this, on an area of about 20ft. in width, an inch of water was gently trickling, keeping the grass soaking. In the midst of this were hummocks, some the size of a hedgehog or larger, one mass of flowers of Silene acaulis, in colour ranging from pale rose to bright crimson There were about fifty or so of these hummocks in about 20 sq. yds. On crossing a barren *arrete* one came to huge expanses of Rhododendron ferrugineum just opening its blooms; and on a large boulder, the top of which was on the eye level, and which was covered with a layer of peat 1ft. thick, was a mass of pink, the tiny flowers of which turned out to be Azalea (Loiseluria) procumbens. How this fared in the full sun without any portion of the top of the boulder buried in the hillside to allow for the intake of water, I cannot imagine. On the shady side of the boulder was a large colony of Primula integrifolia growing in loose moss, the roots coming away completely as the moss was picked off. On examining another huge boulder about the size of a small bungalow, masses of Androsace helvetica were in full flower, fixed firmly in minute crevices of the rock, together with many dead tufts, a fact which tends to prove that this difficult plant is shortlived even in its own home. No living tuft was larger that 4ins. in diameter. This plant was also found in masses, intermingled with Lloydia serotina and Primula Auricula, growing in the crevices of the cliff on the Mutthorn, on the way up to the summit of the Schilthorn.

A DAINTY ALPINE, SOLDANELLA ALPINA. THE FLOWERS ARE LAVENDER LILAC.



THE BEAUTIFUL WHITE-FLOWERED DRYAS OCTOPETALA.

Another walk was through the woods to Isenfluh. The stuffy heat in these fir woods was most oppressive, and plant life, apart from ferns and the waving spires of Spiræa Aruncus, was almost nil. Growing in the damp moss on a large boulder was that quaint creeping orchid Goodyera repens, its habit here suggesting that it is more an epiphytal than a terrestrial species. In the coarse grass on the edge of these woods were large thickets of Rosa alpina in full bloom, and nestling beneath them that pretty cousin of our lily of the valley, Maianthemum bifolium. On leaving the woods one came upon clumps of Cypripedium Calceolus, growing in the gritty limestone-shale slopes, in company with Aquilegia vulgaris and that pretty "rest-harrow," Ononis rotundifolia. In the fields the hay had been cut, and the

workers were busy picking out and making huge heaps of the leaves of the poisonous colchicums, which must make a picture in the autumn.

The last walk which remains to be described, follows the Egertenbach alongside the Allmendhubel behind Mürren. Here nothing new of further interest was found except Phyteuma hemisphæricum and Astrantia minor growing in the fissures of large boulders on their northern aspect.

In this condensed description it has, of course, not been possible to include every plant which was found. Consequently I have confined myself to those which appealed to me most and, in concluding, suggest that there might be many more disappointing places than Mürren for plant-lovers to spend a holiday. H. STEWART WACHER.

THE MARKETING OF FLOWERS

BY GEORGE MONRO.

OF the forty odd millions of people in Great Britain, most at one time or another are purchasers of flowers, but only a very small number of them realise where the flowers come from, or how they are distributed from grower to buyer. It seems, for example, to be a very general idea that nearly all blooms marketed during the winter come from the South of France, but this is entirely erroneous. While, of course, there are large imports—generally from the middle of November until the middle of April—which come from the Riviera and Italy, it is probable that these imported supplies do not account for more than about 20 per cent. of the total sales.

Home products can be roughly divided into two categories, those grown more or less all over Great Britain and marketed in an area adjacent to where they are grown, and (by far the larger proportion) those which are produced in certain specified areas, in which areas the soil or the local conditions have been found by long experience to be more suitable for the growing of these choice blooms. To take, for example, narcissi. The first district to give us outdoor blooms would be the Scilly Isles, from which some 700 to 1,000 tons are obtained each spring. Closely following, in fact sometimes well up to Scilly, is the rapidly increasing area devoted to narcissi cultivation in Cornwall, the industry there being principally maintained by some of the Scilly growers who have for one reason or another returned to the mainland. Slightly later than the two foregoing come supplies from Guernsey and, to a lesser extent, from Jersey, followed by crops from Devon and the South Coast (mainly from the coast of Sussex and Hants), and finally, the principal supplies of all, viz., from the Fen district of Lincolnshire, where experience has proved that the silt land left by the receding water of bygone ages is peculiarly beneficial to the growth of bulbs, and the marketing of the bloom of those bulbs has naturally followed. The steady demand for narcissi bloom has now resulted in an attempt to lengthen the season still more by the transferring of stock to Scotland, and the ground devoted to this, as far north as Aberdeen, is rapidly increasing.

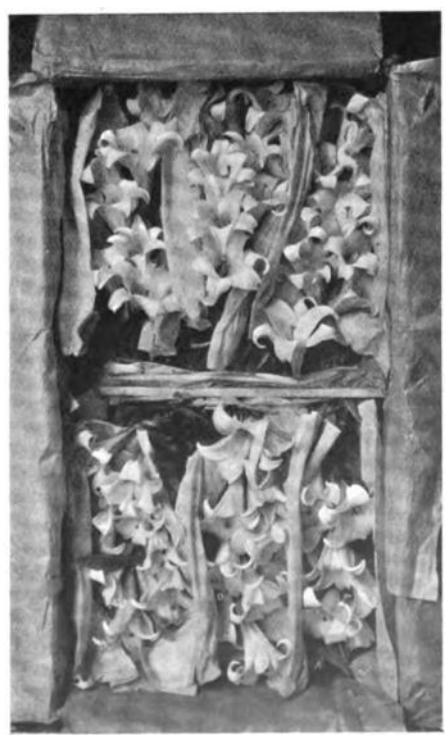
As regards roses, one might think that a rose tree will grow anywhere, and to a certain extent this is so, but immediately one desires to force them, to obtain flowers at the time of year when the tree would not naturally produce them, one will find that except it be happy as to its soil and its environment the tree will not give satisfactory results. The district of Cheshunt in Hertfordshire has been found eminently suitable for the production of roses in the spring and late autumn under glass, and there are many acres of houses in that district solely devoted to this, constituting quite a local industry, employing some hundreds of hands.

In contrast to this peculiarity of the rose we have the perpetual-flowering carnation, which might have been described a few years ago as the "Cinderella" of the flower trade. The first varieties were raised in the United States some thirty-five years ago, and now the carnation ranks only second to the rose in the public favour. Prior to the introduction of these varieties, carnations consisted either of the heavy "Malmaison" type, with its one crop of bloom per season, or of the smaller-flowered, short-stemmed border type, suitable for a buttonhole or for a lady's spray, but not sufficiently long to be used for decorative work. At the present day the perpetual-flowering carnation has the greatest possible range of colour, varying from brilliant scarlet, through all the shades of pink, white and yellow, to violet and mauve. The delicious fragrance of the older varieties is, however, lacking in the present-day flower. A fortune awaits the grower who can combine the beautiful colours and long stems of the perpetual-flowering carnation with the rich scent of the old garden clove.

Chrysanthemums come principally from special districts; Worthing sends enormous quantities to market, especially the early-flowering varieties; Uxbridge (where the largest flower-producing nursery in the world exists), obtains bloom from nearly a million plants every autumn; while at Christmas time the market receives huge quantities from the Lea Valley district, the produce of nurseries extending for some ten miles along the Lea Valley from Edmonton as far as Hoddesdon.

Lilium longiflorum blooms, obtained by the forcing of bulbs imported from Japan, and used so much for church decoration and wreath work, are known to the public as "Harrisii" lilies (sometimes wrongly called the "Madonna" lilies). The principal centre for the production of these blooms is the Hampton district in Middlesex.

One of the largest sections of the floral industry is the forcing of bulbs, mainly narcissi and early and late tulips. These first make their appearance about the week before Christmas, when the public begin to see here and there a bunch of yellow daffodils ("Golden Spur" or "Henry Irving"), and a few white, red or yellow tulips, probably of not too high a quality. To obtain these early flowers only the strongest bulbs are used, and even then the grower is often lucky if he manages to make half the bulbs give marketable blooms; but directly the turn of the year comes, quantities increase enormously and the extent of the trade for the two months of January and February can scarcely be credited by those not handling the tremendous quantities coming in daily. Years ago most of the bulbs for forcing were grown in Holland, and the general public are still under the impression that the position remains the same. The bulk of narcissi bloom, however, as well as a very large proportion of the later tulips, is obtained by the forcing of bulbs grown in England, and we look forward to the time when we shall be able to supply all our requirements entirely from home-grown bulbs. The public will have an opportunity at the Wembley Exhibition of seeing a wonderful show of 200,000 Darwin tulips in full flower, every bulb of which was raised in Lincolnshire.



THE BLOOMS OF LILIUM LONGIFLORUM NEED CAREFUL PACKING BECAUSE THEY READILY BRUISE.

The major part of the distribution of all these supplies is through the various markets, which may be divided into three sections, the first comprising only

Digitized by Google

the one clearing house of the trade, Covent Garden; the second—the markets of the larger provincial cities and towns, such as Manchester, Liverpool, Birmingham, Leeds, Glasgow, etc.; and the last, the smaller provincial markets found in most towns of a considerable size. While the second draw their principal supplies direct from the growing districts, every single market in Great Britain depends on Covent Garden for a considerable proportion of its requirements.

For a good many years Covent Garden Flower Market has been one of the sights in London to visit, during market hours, where one can see—in addition to the wonderful and varying colours represented by home produced as well as foreign bloom—the delivery by road transport of bloom produced within a radius of some twenty miles; delivery by railway vans from districts further afield, and (in spring), thousands of packages from the South of France. The method of sending the latter is peculiar to that trade, these packages being the only ones which come to the market through an intermediary in addition to the usual railway company or carrier. The South of France is a good example of those districts where one finds a large number of small owners, many of whom occupy ground of not more than an acre in extent. They pack their produce in very light split cane packages and send them by "Colis postales"—a type of parcel post—to one of four or five transport agents in Boulogne, who consigns it to the London market in bulk. Commencing about Easter time, the visitor will be able to see each day some thousands of long narrow boxes containing roses from English glasshouses. These include all qualities and are graded to perfection, some growers even making as many as five different grades of bloom. Again, the visitor will see thousands of boxes (of a similar size) containing carnations graded to the same extent. Also "Harrisii" lilies from the Hampton district, in larger boxes, invariably six bunches of twelve blooms (or buds), these coming up by road to ensure the good condition of the bloom to the purchaser. Then, in addition, is the narcissi bloom of the Scilly Isles and Guernsey, packed tightly in boxes constructed of light wood to reduce weight and therefore railway charges, which from some of the more remote parts means an additional charge of about one penny per bunch.

(To be continued).

THE CARE OF RHODODENDRONS IN SUMMER

A LITTLE advice may be of some use to lovers of rhododendrons who find that some of their plants are hanging back and are not so healthy as they might be. There is little doubt that although rhododendrons are easy to keep alive, they are difficult plants to keep in the best of health without a certain amount of cultivation, unless one is lucky enough to live in the moist atmosphere of the west coast. This applies to hybrids as much as to species. Of all the gardens that I have seen there are perhaps a dozen in which the rhododendrons were really well grown—and it must be remembered that in nine cases out of ten poor growth is the fault of the cultivator. It may be thought that this statement is too strong, but I can assure you that that is not the case.

There are three main requirements in the well-being of rhododendrons: good drainage, moisture, shade; it is not just to the plant to be satisfied with some straggling, small-leaved hybrids in a bed in the middle of the lawn, where they are exposed to full sun and to every wind that blows. They will probably live and produce flowers, but a rhododendron is a fat, rich-looking plant in good health with foliage almost as handsome as the flower. The worst of it is that few people have ever seen a well grown rhododendron unless they have visited the west coast and so the old proverb about ignorance and wisdom comes into play.

The first requirement is probably the easiest, because most gardens are well drained. Rhododendrons will grow best on a slope and in a porous soil. If the loam is heavy or the soil be clay, a certain amount of peat or leaf-mould and gravel should be added.

The second is more of a problem and one where most gardeners go wrong. It must be remembered that rhododendrons are surface rooters and that it is a great mistake to plant them too deep. This is the real cause of a great deal of poor foliage. The top of the ball of roots should only just be covered by the soil. On the other hand, because rhododendrons grow best on sloping ground, it should be remembered that in a drought such ground is extremely difficult to water. The water merely runs off the ground and even after an hour's soaking may have penetrated but half an inch.

THE CORRECT MULCHING OF RHODODENDRONS.
Note how the saucer is level so that all water reaches the roots.

The best method to simplify watering is to level the ground around a rhododendron or group of plants. It is not a laborious task for it only means scooping out a little soil from the uphill side and banking it up on the downhill. The result should be a saucer depending in diameter on the size of the plant, in the middle of which sits the rhododendron knowing that every drop of water falling into the depression will reach its roots. The depression should be filled with fresh leaves, newly mown grass, or peat moss litter. It will be found that every rhododendron planted in such a depression will respond to a quarter of the watering and that the moisture will be retained longer. Watering should always be done when the sun is off the plant, but it will be found that with good mulching little will be necessary except in times of real drought.

Rhododendrons of all shapes and sizes require more or less shade. As a broad rule the larger the leaf, the more shade is necessary, but no rhododendron is a sun-loving plant. What sun they get should be intermittent, perhaps for an hour in the morning showing between two trees and then again later on as it moves towards the west. The worst tree to grow along with rhododendrons is an elm, for it is a root robber of the worst kind. I have seen a nursery bed under

Digitized by Google

the shade of elms whose roots were regularly cut. One escaped the axe and within six months over two pailfuls of fibrous roots were dug out of a bed 4ft. by 12ft. Naturally the seedlings suffered, for every drop of nourishment was stolen from them by the tactics of the elm, which seems to have an uncanny nose for tit-bits.

It might seem that the quest for the perfect rhododendron was full of pitfalls, and so it is, for perfection is never easy to obtain. On the other hand, once a rhododendron gets what it requires, very little attention is needed in future, perhaps an occasional watering, and a weeding over a year of its immediate surroundings, a test every now and then to see that roots from other plants are not robbing it, a refilling of the saucer when leaves or peat begin to wear away, disbudding if it shows too many flower buds, and a careful examination of its roots and soil conditions if the leaves yellow or the growth is unduly retarded. This is not very laborious and the result is well worth the trouble. E. H. M. Cox.

THE WILD GARDEN

THIS term is very loosely used in ordinary conversation. It may mean anything from a most careful and artistic imitation of wild Nature to an untidy spot where odds and ends of surplus plants are cast to fight out, unaided by the gardener's hand, a losing battle with bramble and weed. To call this latter a "wild garden" is an obvious misnomer, for it is neither "wild" nor a "garden."

The former is one of the most difficult tasks to accomplish with any success and requires artistic gifts which, unfortunately, we do not all possess. This, however, is, I consider, the true wild garden, namely, an imitation of Nature on a small scale: the arranging in the space of an acre or two flowers indigenous to the countryside in an attempt to produce the beauty that Nature spreads over large stretches of country; in fact, to aim at a sort of microcosm of her loveliness.

What charms us when we take our walks abroad is the profusion of Nature: the wild riot of the June hedgerow, the wealth of primrose or foxglove in the woods, the sheets of blue and pink in the brake where bluebells and ragged robin intermingle, the starry carpet of wood anemones.

To bring some of these sights together in a comparatively small area and to get even a fraction of the natural effect is by no means easy to accomplish.

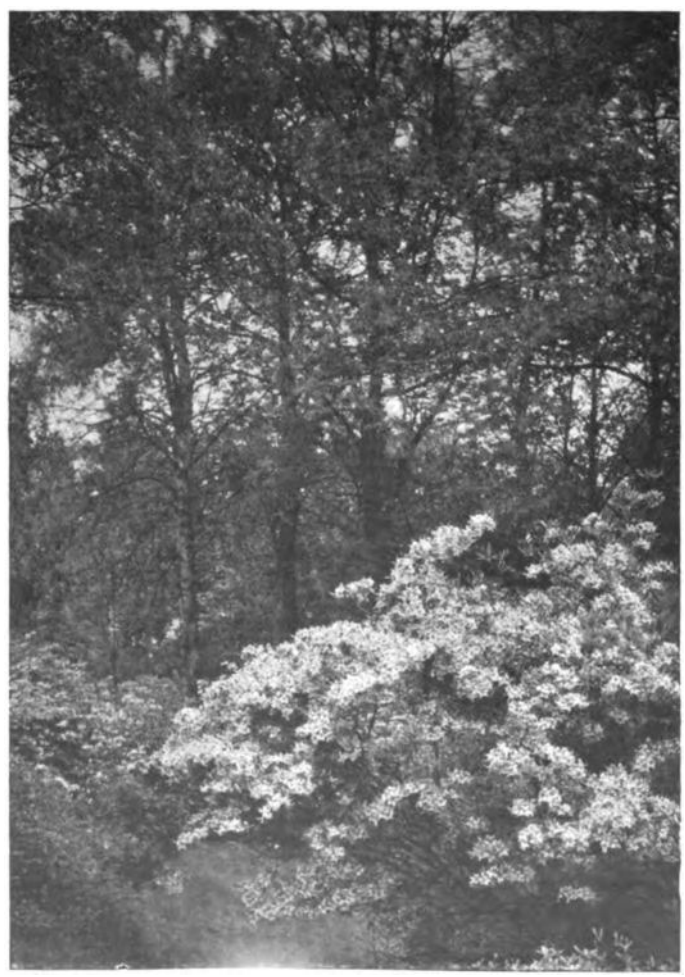
Bacon, in his essay on "Gardens," gives his idea of what a wild garden should be, and, even if there are many points in his list of flowers and their arrangement that seem open to criticism, his description is a fair one, though he introduces some garden flowers, such as "Sweet Williams Red" and also clipped standard bushes.

He is very definite as to its area, and allots 6 acres in a garden of 30 acres. "Trees," he says, "I would have none in it"—this seems rather an unnecessary deprivation—"but some thickets made only of wild briar and honeysuckle and some wild vine amongst and the ground set with violets, strawberries and primroses. I like also," he continues, "little heaps in the nature of mole hills, some with Wild Thyme, some with pinks, some with periwinkles." His list is too long to quote, but it gives one the rather irreverent opinion that the wisest man of his age wrote down pictures that passed before his mental vision and never attempted to carry out his ideas.

Perhaps it may be pedantic to find fault with his use of such a very convenient phrase as "The Wild Garden." It is generally used to describe a part of the garden less formal and cultivated than the rest. I use it (for convenience) to designate an acre or so of land evidently taken in from a field and planted with rhododendrons, large clumps of pampas and tritoma, some good kinds of pine, may trees, shrubby spiræas, buddleias, and, in a deep pit from which, evidently, sand has been dug, the great stems of the giant polygonum form a miniature forest. These last are handsome here and harmless, but in the cultivated ground soon become an ineradicable curse. This, I know, has no claim to be called a "wild garden," but it would be difficult to find a more convenient name for it.

Should you possess a bit of woodland or a stream, a bit of outcropping rock, or even a hedgerow bordering your garden, there is a way of encouraging wild flowers that will give a great deal of pleasure for a small amount of labour and very little outlay.

Many years ago, the plates in that most useful book of Miss Jekyll's, "Colour in the Flower Garden," incited me to attempt to carry out in a large wood some of her ideas. The working out of these schemes proved a great source of pleasure and amusement. I say "amusement" advisedly, for it is rather a relief to turn to this sort of gardening after the digging of borders and pruning of roses and such more business-like occupations. Should you have some wild flowers in your wood or by your streams—and it is seldom that you will not have half a dozen varieties—it is wonderful what results you can get by taking the side of the flowers against their enemies, chief of which is the bramble. The way your wild flowers respond to your help is extraordinary. Your few scattered primroses become large patches, while the foxgloves particularly are inclined to take liberties and smother the other flowers.



AZALEAS IN TI 'DEN AT MUNSTEAD WOOD.

My wild strip now consists of some 250yds. of broad bank from 6yds. to 8yds. wide. With the aid of hook and grubber the flowers have taken heart and spread. Primrose, wood anemone, bluebell and foxglove fairly carpet their respective stations, mingling with and merging into one another. The ditch in the hedgerow shows a variety of ferns, formerly hidden by scrub and bramble.

It is also an interest to introduce white foxgloves and violets, forget-me-nots and daffodils among their wild relations.

Those who have larger scope of action will find, set out in Chapter III of the book I have mentioned, the way in which such work should be done in the best possible manner. Should you have no place for a wild garden but have some imagination, the study of that chapter will give you a very pleasant hour.

M. J. M. VICARS-MILES.

CORRESPONDENCE

GENTIANA ACAULIS.

"WHIMSICAL in flowering" is the description given by many gardeners regarding this plant; and it has even been suggested that, in order to provide a necessary bacteria, soil should be begged from the spot where it flowers well. The following hints are easier to follow and may be of service. I may add that all our long herbaceous borders we have edged and are edging with these enchanting blue ribbons of triumph.

A friend described the gentian in its own home as "patches of brilliant blue in the meadows." We have tried breaking gentians up every two or three years and replanting in small clumps, guessing that root room is required for successful flowering. Here is a useful wrinkle: observe the growth of the plant radiating in little green spikes from the central piece, and each spike, if down on the ground, throwing out rootlets. Doubtless in the Swiss meadows the spikes are pressed to the soil by the weight of the succeeding summer growth of other plants. Here the poor bits are too often to be seen sticking up futilely and presently to wither off. As soon as the gentians have flowered we strew the crowns and work in carefully sifted soil. Then each growth is provided with stuff to root in. I may add that, having no lime in the soil, we grow ours in lime rubble, sifted leaf-mould and loam.—(Lady) ROSAMOND CHRISTIE.

THE PRUNING OF PRUNUS TRILOBA.

I WISH to thank "A. O." for his letter in THE GARDEN of April 12th, page 248. Both he and I apparently have had our years of responsibility for the same tree, and given the same conditions it is not likely that there can be very material difference of opinion between us. My years of responsibility were about seven, but that was long before hard cutting back amounted to the status of a cult, if I may so term it. "A. O." now refers to pruning annually, against which I have said nothing and quite believe in. I referred exclusively to his instructions for hard cutting back, which I said was lamentably easy as compared with pruning, which requires skill, and I used other terms perhaps, to which I cannot now refer. I made a sharp distinction. My letter, I fear, was somewhat uncompromising, but it was written solely to meet the equally uncompromising instructions given by "A. O." for hard cutting back, and, while referring to conditions vividly in my mind for which I held it to be quite wrong, made no attempt to cover all conditions and circumstances. The illustration that appeared with my letter was not precisely to support my contention, and it is the best that "A. O." could have in support of his own. That, however, I was not sure of until I read his last note, and therefore I do not feel that it calls upon me to withdraw or modify. "A. O." must please forgive an old conceit of mine that skilled and careful pruning will always go one better than hard cutting back. His tree on a south wall making strong wood is as well suited as any could be to submit to it. "A. O." remarks that if these vigorous young shoots are left unpruned for a year or two it is his experience that specimens in a few years grow away from the wall and get out of hand. To that I would say that a few years need not be in question if attention is given annually, and, further, that surely it could only happen for want of the pruning that I advocate. It never does happen in the case of a peach tree, also unnaturally placed against a wall. I question, indeed, whether I advocate anything more for Prunus triloba—making due allowances—than is always considered right for a peach tree. The "bee in my bonnet" I might mention is disturbed only when we are instructed to cut hard back without being permitted to exercise that skill and discretion which is the pride of most of us. By the way, I have not said that annual pruning results in stubby and comparatively weak shoots. It is hard cutting back that I have known to do that. Therein was my argument, and skilled pruning is to avoid that result.—R. IRWIN LYNCH.

A READER'S ROCK GARDEN.

I AM the possessor of a very small rock garden. It has to be small, for no one touches it except myself, and I have only the week-ends and holidays in which to look after it and to keep in order the rest of my flower garden, for my gardener is fully occupied with the fruit and vegetable garden. It is therefore a very small rock garden, and presents a problem which is difficult of solution in proportion as the garden is small. I submit this problem to you and your readers, and shall be glad of any hints that you can give me. How, in so small a garden, can I get the maximum of flower through the longest period? It can only be done by growing *together* plants that flower at different times. What plants and, above all, in what combinations, are suitable for the purpose? This is where I need help. Aubrietias, helianthemums and the like have their place, but choke off anything else planted among them. I have succeeded with some combinations, and to illustrate my meaning may mention one or two. (1) Kabschia saxifrages with Campanulas Raineri or Zoysii; (2) Anemone sulphurea with autumn or spring crocuses of the alpine varieties; (3) AA. apennina, blanda or blanda scythinica with dianthus; (4) Iris reticulata with D. neglectus and so forth. I am trying A. fulgens and the Caen anemones with Aquilegia alpina and Aster alpinus. The anemones are all right and their successors look promising. Not only do you prolong the flower season of the garden in this way, but I am convinced that most alpines do better if other alpines of *the right kind* are planted with them. Their roots need companionship or competition. I send a photograph of a bit of wall garden taken early last year. You may see Saxifraga pyramidalis and other saxifrages on it. Some of the spikes of S. pyramidalis are over 2ft. 6ins. long. They had been undisturbed for four years from time of planting. You had some correspondence on this point last year.—A. C., *East Sussex*.

BORDER CARNATIONS IN POTS.

IT is always interesting to read other peoples methods and opinions, as much good can arise from such an interchange. The method of growing border carnations in pots as advocated by Mr. Coutts (page 219) differs somewhat from the method I have frequently practised, as the following notes will show.

The layering is done in early July. For this purpose plants which have previously been flowered in pots are used and the layering is done for convenience in a frame. The lights are kept on for a few days after layering and then abundance of air is allowed, the lights still being used as a covering protection at nights and during a storm. With this treatment the young plants are ready for their 3in. pots by early September, and put back into a frame they quickly fill the pots with roots and are put into their flowering pots (6in. for a single plant), in October. These plants are wintered on a shelf close to the glass in a vinery where the frost is excluded. Obviously, careful watering must be the rule during winter, but this is no difficulty to the experienced gardener.

In February when the vinery is started the plants are removed to a cool greenhouse, taking the place of Zonal pelargoniums, which have by that time finished flowering. Here they are grown along steadily under cool conditions and usually commence flowering during the latter half of April. I have usually grown two batches as a succession, treating one half as outlined above and the others on lines almost identical with those advocated

SAXIFRAGES ON A WALL GARDEN IN EAST SUSSEX. S. PYRAMIDALIS ON THE RIGHT.

Digitized by Google

by Mr. Coutts. Usually the best flowers are procured from the earlier batch, which are put into their flowering pots in autumn. There is, of course, a better opportunity of feeding with liquid manure the autumn potted plants and this may make the difference. Then again there is the distinct advantage of having earlier flowers and the plants after flowering are available for layering.

I have found it a good plan to select the best plants after flowering for growing along a second year. They are potted into 9in. pots in July and grown along under cool conditions. The weaker growths are removed and the others are supported with a thin bamboo cane, and give quite a number of good flowers the second season.—W. F. ROWLES.

WALL GARDENING.

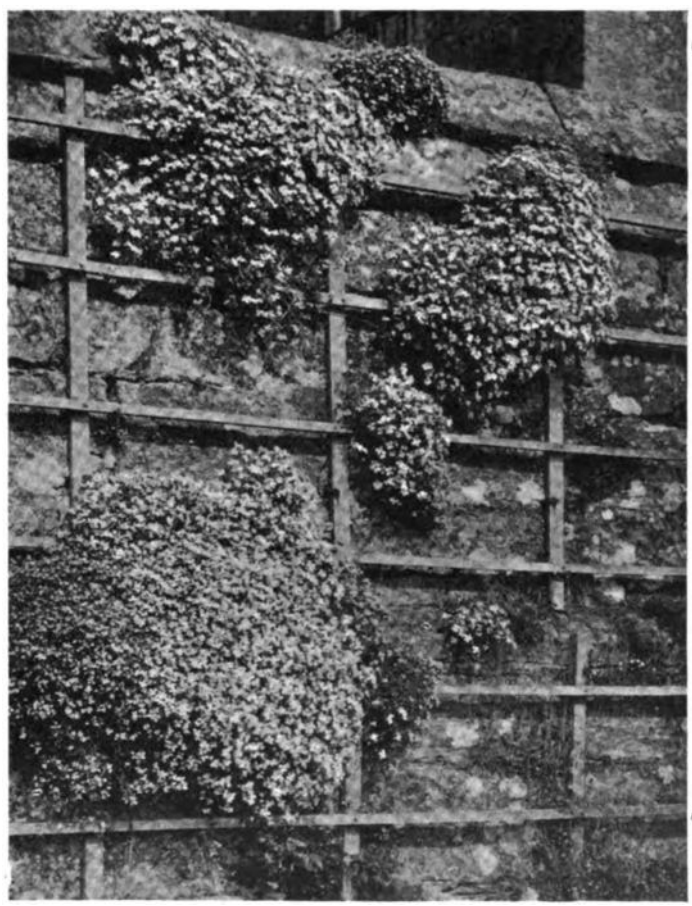
THIS phase of gardening is not so popular as it might be. There are, in many gardens, ugly walls that could be made beautiful by planting aubrietias, alyssum, iberis, snapdragons, etc. However, a certain amount of grouping is desirable, or else spottiness will be the result. I enclose a picture of aubrietias on a wall, in the gardens of Mr. William Robinson, at Gravetye Manor. At the time of my visit, these aubrietias were one of the features of the garden.—H. C.

THE USE OF GARDEN LABELS FOR ALPINES.

I AM afraid I am quite unrepentant on the subject of labelling alpines, even though the weight of the editorial pen is against me (page 249, April 12th). But, after all, it is surely a matter of individual taste, of a personal balancing of advantages and disadvantages. For myself I so object to the disadvantage of conspicuous lettered labels for diminutive alpines that I prefer the admitted disadvantages of numbered labels, *i.e.*, the necessity of carrying a notebook even in wet weather and the necessity of extra scrambling over the rocks to find out the number of a label—a disadvantage shared to some degree by written labels, which are seldom legible from the paths of the bigger rock gardens. That is my personal balancing of advantages and disadvantages: you and Mr. Hillier balance differently. *Quot homines tot sententiæ.*

But in your last criticism of numbered labels you go beyond a question of personal choice and make a statement founded on a misapprehension of fact. You say that the danger of wrong nomenclature would be doubled by reason of two lists, one with numbers, the other with names. But there are not two lists, but one, though there may be duplicate copies of the list. The original list would be complete in itself with numbers on the left-hand sides of the pages and the names filled in opposite the numbers. It is true that the names may vary from time to time, but if you erase the name of a dead plant and replace it with a new name when you use the numbered label again, why should it cause confusion in nomenclature? Surely the fact that a numbered label could be used for another plant would tend to lessen a common cause of confusion in the minds of inexpert visitors when the useless written label of a dead aristocrat is left protruding from an invasive commoner. I have seen this even at Kew.—EDWARD S. LYTTEL.

WHEN I read Mr. Gerald Hillier's very interesting article on this subject in THE GARDEN, March 29th, I said to a friend it was a timely article and one that would prove useful to many lovers of garden plants. Then I read the Rev. E. S. Lyttel's criticism on the article in THE GARDEN, April 12th. I again perused Mr. Hillier's article and liked it better the second time, as I was, perhaps, more critical, and found it to be a practical one. The labels are shown in Fig. 1 grouped to enable the reader to compare and select. Labels in a garden border do not present the same crowded appearance, nor do they in alpine borders where the labels are of the right colour. Personally, I would much prefer a large label than petty economy in a garden. A neat label with name plainly written upon it is rarely noticed because the visitor's attention is at once directed to the plant or plants. But a label bearing a number which is duplicated in a private book is an eyesore and vexing to the visitor. The Rev. Lyttel's system would entail as many labels as Mr. Hillier's with the addition of a book of reference, *very convenient to use on a showery day!* The numbered labels pressed into the soil almost out of sight would draw the visitor on to the borders to find them and, if the plants were robust enough, they would, probably, obscure them altogether in many cases. The Rev. Lyttel's system is a laborious one, and would prove uninteresting to anyone except, it may be, the owner. Therefore, readers who are beginners should not hesitate to adopt Mr. Hillier's stystem, which recommends itself to all, except, it may be, a few who love fads. I have seen some of the largest and most costly rockeries, both private and public, in this country, and the plants on all were labelled plainly, as described by Mr. Hillier. I never have read during the past forty years a weaker argument nor one with less point to it than the one by the Rev. E. S. Lyttel on page 249.—G. G.



AUBRIETIAS ON A WALL AT GRAVETYE.

THE ALPINE LAWN GARDEN.

A CORRESPONDENT of THE GARDEN writes asking me to give a few further details about making an alpine lawn garden in an old stone sink. He asks if I gave the depth—3 to 4ins.—correctly in my recent article on the subject (page 244), and what about drainage, and what soil should be used? Also, should the sink be sunk in the ground in full sun?

Yes, I gave the depth correctly; 3 to 4ins. is about the average depth of the sinks, and I find from experience that this is ample for the plants' needs. The soil can be slightly heaped and undulated, which gives a little extra depth, besides adding interest to the tiny landscape. The stone water-troughs and pig troughs that one can pick up in some districts are, of course, deeper than the sinks, but there is no great advantage, culturally, in this.

Drainage is, of course, absolutely necessary. Sinks have their own sink hole, usually at one end. In putting them in position, and before filling with soil and planting, it is a good plan to test them with water, to make sure that they are set at such a level that all water drains to the hole end and so away. A tilt in the opposite direction is very bad. A big crock over the hole and a handful of smaller ones around are all that are necessary. One hears of "scientific drainage" in these matters, but a tilt to run the water in the right direction and a few crocks to prevent the soil from following it are all the science needed and might be more aptly called common-sense. As to soil, this, too, is a simple matter. A good gritty potting mixture, loam, leaf-mould, sand, grit or broken stone, mixed "to taste." That is all. I have never sunk my sinks in the ground. I like to stand them on something. Low balustrading near the house, and the piers of brick or stone garden steps make good places to put one's sinks and troughs. Failing these—and it is nice to have them near the eye—one may raise them on short lengths of stout logs or build little piers of old bricks for them to stand on; or one may use—if one can get them—old stone stack piers. Always a site should be chosen near the house, for they are, perhaps, the most intimate of all forms of gardening and should be kept near at hand. One should be able—and tempted—at any hour of the day or night to go out and water the sink garden, to enjoy its flowers, or to stab a slug.

Stone sinks and troughs are still quite easy to pick up in any part of the country. Builders' yards are the most fruitful hunting grounds, and sinks are to be had very reasonably. They are constantly being taken out of old houses and replaced by glazed earthen ones. On no account use glazed earthen sinks for gardening in. Not being porous, they are bad for the plants, besides being abominably ugly. And as to concrete, all I can say is, before using it—go and look at the Mappin Terraces.—CLARENCE ELLIOTT.

NOTES FROM CONTRIBUTORS

THE PROPAGATION OF CHOISYA TERNATA BY CUTTINGS.

I HAVE rather a remarkable experience to relate with regard to some cuttings of green shoots which I took of Choisya ternata in May *two years* ago. They were placed in a pot of sandy soil in the shade in an unheated greenhouse. Six cuttings were taken and two only died. The remainder are still quite healthy, with green leaves and buds showing, but there are no roots. At the end of the first twelve months I turned them out and found only callus formed. Also a month ago I turned them out again and still found only callus. The questions which arise in one's mind are: How long is it possible for green shoots to live without roots, and also if at the end of two years' existence in this state there is any chance of roots being formed. I wonder if any of your readers have ever had similar experience with cuttings. I know this sounds rather like a "tall story," but I can vouch for its accuracy, as also can several gardening friends who have seen them. — H. STEWART WACHER.

GENTIANA VERNA.

POSSIBLY no alpine has had more written about it or more notice taken of it than Gentiana verna, and on that account it ought to feel highly flattered with itself, but, on the other hand, it ought to feel thoroughly ashamed at the miserable response it oft-times yields to all this fuss and coddling. Doubtless the reader will already have assumed that the writer is going to give yet another recipe for its cultivation—no such thing! All my days garden lovers have been writing letters and giving instructions to dig holes ever so deep and fill them with sand, soil, stones, sticks, slates, broken bricks, granite chips, lime, peat, loam and anything else that one can possibly imagine, and that, too, in the most weird proportions, coupled with endless ramming and jumping on the composts. The beds to be placed in sunshine and shade, shelter, dampness and drought, together with endless waterings and, very possibly, glass bell-globe coverings, which latter certainly seem most appropriate, for, in a short time, be it sooner or later, the charming little creature sulks and dies, leaving no trace of its abode save a little tuft of rank grass, if it by chance hailed from the Emerald Isle, and who among us has not bought Miss Verna from there? Then with the funereal tally-pin, of course, as headstone, coupled with the appropriate bell glass, one feels prone to drop a silent tear over the departed, the labour expended, and the two and sixpence past and gone. No! what I would dearly like to know is, if there is any garden in the British Isles where the plant does really grow and look happy and contented. I do not mean linger between life and death, seemingly yearning for the latter, with perchance an odd dozen blooms (that I can aspire to myself), but really growing and flourishing year after year, as would clumps of Anemone angulosa or Adonis vernalis, and with an equal length of happy days. If any of your readers could introduce me to such a garden I will spare no efforts to find myself there, take off my hat and carefully study its requirements. I have seen many gardens, but never yet had the good luck to see one where Gentiana verna grew as I would like, and almost doubt if one really exists.

Notwithstanding all the nasty things I have said above about this charming little alpine, is it not just possible that it is a short-lived plant, and ought to be regularly raised from seed, and that the plants we invariably get are nearing the end of their days before we become their owners, while the seed does not ripen and germinate in our somewhat treacherous climate, but requires brighter sunshine and an Alpine atmosphere. I really wonder if this is not the solution to the many disappointments. In the Alps it appears dotted over the fields as though raised by seed, and not in very large, spreading clumps. Those who have raised the plant from seed will be better able to say whether it thrives better and lives longer than can the writer, who has never done so, but merely bought in plants times without number, and always with the same sad results.—FORMAKIN.

CELSIA CRETICA.

THIS plant is often grown in the cool greenhouse or conservatory for decoration; but there is really no need to treat the Cretan mullein, as it is occasionally termed, to indoor conditions, as it is perfectly hardy and far more at home among other hardy plants in the border or shrubbery, where its stately growth and primrose yellow spikes are seen to perfection. Here it is managed in a mixed shrubbery, small groups in flower looking quite handsome peeping up here and there among the other plants during a good part of the summer. We let plants seed and sow themselves, removing or transplanting the young stuff to where it is wanted. This is a simpler and more natural way than sowing in specially prepared conditions and, incidentally, a surer way too, in my experience, to get strong transplantable seedlings. Another point worth noting is that when this plant is grown among shrubs it rarely wants staking, the more or less all-round protection from the bushes preserving its erect habit. In their early days the leafy tufts of this plant closely resemble foxgloves; indeed, its whole habit and height does. Young plants should still be procurable, and can be planted to bloom this summer—as such would have been raised last autumn—C. TURNER, *Ampthill Park*.

DUTCH CROCUSES.

BAD as the weather has been, I have nevertheless had a great deal of pleasure out of my fifty-nine varieties of Dutch crocuses. They fill two long beds of 4ft. wide and are planted in solid blocks of fifty. With the splendid old yellow the exact number is sixty. The surprise to me is that I have to dethrone Dorothea from its proud position as being *the* Dutch crocus and in its stead put Maximilian. I had two beds of 4ft. by 16ft. with no other variety in them, and no one could wish for a more beautiful sight than the solid masses of pearly blue-mauve surrounded on all sides by decently short grass. This spring, of all springs, it may be that I should not say anything against the sun; but, as many have doubtless noticed, King Sol does not improve the complexions of crocuses. He is no respecter of persons. Dorothea, Maximilian and Philomela are treated just as the old purple Albion and purpurea grandiflora, and when under his rays have what for most of us seems a less becoming red tone in their mauves and purples. I have two questions to ask. First, is Dorothea the same variety as that called Maximilian? They are very close to one another if they are not identical. In my trial blocks I could not see any difference, except I *thought* Dorothea was not quite such a large flower, and it did not do quite so well. This might only be that the bulbs of Dorothea were not quite up to the knocker. Another fact that bothers me is that although I have hitherto regarded the names as synonymous, a great raiser of seedlings in Holland, from whom I got the collection, sent me both varieties and charged different prices for them. My second query is, "Does anyone know when the Dutch began to raise seedlings in quantity?" They have been at the game for a very long time. James Justice, who knew the bulb fields of Holland very well, says in his "British Gardener's Director" (1764) "that Mynheers Voerhelms and van Kampen sold 100 bulbs in 12 sorts for one Guilder" and also that on account of the "abundance of their varieties raised and their prices so low," it was only worth while to let them sow themselves. With such a past no one need expect the improvements in Dutch crocuses to be either many or great. My collection not being limited to varieties of any particular age proved such to be the case. The pale striped Mme. Mina is still one of the best striped, but being one of the early ones to flower suffered severely when the 3ins. of snow came. For convenience of reference I am going to take whites, mauves, purples and stripes in turn. The whites were the easiest to judge. Two friends whose opinions I asked and who had no idea of the ones I had selected each gave in the same numbers as first and second, and one of them gave the same as my third choice. These were Kathleen Parlow, the spotless white with large orange stigmata; May, the compact cup-shaped flower with some purple on its stem; and Honorine Jobert, the somewhat small but extremely free white. There was not much difference over the mauves. Maxmilian or Dorothea (for the difference is very little, if any) was an easy first. Then came Lord Duncan, which was decidedly similar but for its much darker stem. Margot was a great favourite, almost a pale bicolor with the three outer petals shaded and tipped white and the three inner a pale flushed lavender. I do not like tall crocuses, and as Margot was tall, it did not appeal to me as otherwise it would have done. The handsome dark striped Fantasy got a bad mark on this account. Philomela was mauve number four. It is several shades deeper in tone than any already mentioned, but when seen in an evening light or when shaded from an afternoon sun it takes some beating. Probably the shade would not suggest "powdery blue" to anyone, but it did to me, and hence my note says "powdery mauve." It is a very blue-mauve in shade. Purples were the teasers. I always say if one is out to make *selections*, at all costs one must avoid making nothing but lists. It has been difficult to settle on the four, which number I made my limit. Hero I put first because of its taking shape, its rich deep shining colour and its being able to rough it. If anyone plants it for a show, the bulbs should be put in rather closer together than usual. It is not as floriferous as one could wish. Purple Beauty, purpurea grandiflora and Albion (purple self) I couple with Hero in the order in which I have given them. Lastly, I come to the striped varieties. Let me say at once that to me "distance lends enchantment to the view" and robes these in a beauty which is not very obvious at close quarters. The pretty palish mauve of Mme. Mina, or the rather darker Minerva, or old Albion, darker still, look well in a mass when you are not too close, but the nearer you are the more the striping shows itself and the less pleasing do they become. Still, as tastes differ, for those who like stripes I should suggest a trial of these with the addition of Oscar, a sort of semi-striped, as the outer petals are almost selfs. It is one of the darkest of all this type. I must draw attention to Distinction, as it stands

Digitized by Google

by itself with regard to its colour among Dutch crocuses. I have seen it described as a red-pink, but to me I can never see that it gets beyond a mauve-pink. It certainly is the pinkest crocus I know, but to make it appear the real thing I would have to put on my rose-tinted spectacles. Another variety that refuses to be catalogued with any other is Bleu Azure, on account of its extreme earliness. It is not the very early Harbinger, as I was unable to secure any corms, and so I have not been able to test the two together. I imagine the last named is the earlier, but Bleu Azure, takes some beating, as the little patch was in full blow some time before any other of the collection. It is a pale edition of purpurea grandiflora and very free. Everyone knows what delicacies crocuses are to mice and how by some mysterious means they are able to tell that 4ins. or 5ins. below this or that spot a crocus lies buried. James Justice, to whom I have already alluded, tells us on page 219 of his "British Gardener's Director" how we may keep them at bay by putting a little dry soot into each hole made for the crocuses "to prevent mice falling upon their roots." I wonder if this is ever tried nowadays in gardens where these destructive little animals are a nuisance.—JOSEPH JACOB.

NOTES FROM FRANCE.

FOR anyone who thinks of Cryptomeria japonica as a giant conifer from Japan, the variety Vilmoriniana must come as a surprise, for instead of growing to a considerable height it only grows at the rate of a few inches a year and has a very bushy and compact habit. The plant was discovered quite by chance last autumn by Mr. Hornibrook, the specialist in dwarf conifers, when paying a visit to the collections of Mme. Ph. de Vilmorin at Verrières-le-Buisson, near Paris, a place, by the way, worth a visit for anyone who has several days to spend in the French capital. There it makes a very striking bush in the rock garden under the name of Juniperus chinensis japonica, a name attached to it when it was introduced from Japan in 1903. Although the nomenclature had been at times questioned, it never occurred to the mind of anybody that it could be a form of cryptomeria so different was the plant from any known form of this genus. It wanted the keen eyes of an expert to determine this, and Mr. Hornibrook is to be congratulated on his discovery. The new sub-species was described in THE GARDEN, January 19th (page 37), and the name of Vilmoriniana given to commemorate the name of the introducer. The illustration given here will give a fair idea of the appearance of this new pigmy conifer. The leaves of Saxifraga (Megasea) ornata (probably a hybrid form of S. ligulata, and very beautiful in the early spring) on the bottom left-hand corner will serve to give the correct proportion. The exact measurements are 75 centimetres in height and as much in width. The habit is upright and stiff. So far this large-sized plant is unique, apart from a few very small plants, one or two of which are in the possession of Mr. Hornibrook. But as cuttings have been made in numbers last season in Verrières it is expected that this interesting new shrub, very ornamental indeed and so different from anything else known in dwarf conifers, will soon be able to find its way into the grounds of all garden lovers.—C. L., *Paris*.

AMERICAN WILD FLOWERS CULTIVATED IN ENGLAND.

LAST year, after visiting in America and seeing how the wild flowers grow which we in England cultivate so carefully in our herbaceous borders, I came to the conclusion that to compete with Nature as a gardener is quite out of the question. It is better to go along with Nature, letting her give you a hint or lift whenever possible instead of so often trying to improve upon her. In the woods and wild spaces of the State of Maine, which is in the north-east corner of the United States of America and known as New England, wild flowers and flowering shrubs abound. They are so numerous that it would be quite impossible to enumerate them all, so that I only mention a few which took my fancy

CRYPTOMERIA JAPONICA VILMORINIANA.

and which flower between May and October. The small scarlet columbine (Aquilegia canadensis) is one of the earliest woodland plants, and is very graceful in form, nodding its brilliant heavy head all ways in the breeze. Its height is from 1ft. to 2ft., and it spreads all over the woods.

In the meadows the orange red hawksweed, which we often sow as an annual, is looked upon as one of the deadliest weeds, but it is most striking grown in masses, and there are few flowers of its colour. So also does Rudbeckia hirta, known to all Americans as Black-eyed Susan. This flower flourishes as profusely in dry grass fields and pastures as does our white ox-eyed daisy, and it would be a great idea to plant many clumps of it in grass to follow bulbs which have been flowering in the spring.

Along the hedgeless roads meadow sweet (Spiræa salicifolia) with its rosy-tinted, spire-like panicle of fleecy flowers is a most fascinating shrub, so is hardhack (Spiræa tomentosa), a beautiful plant, with a flower-spike which is more slender than meadow sweet and of a very much deeper shade of pink. Both these are excellent for picking big branches off, as they last a long time in water.

Mountain laurel (Kalmia latifolia), which grows from 3ft. to 6ft., is very striking, with glossy dark green leaves which are arranged alternately along the branches and often in dense terminal clusters and has quaint pinky white flowers growing in a flat bunch at end of stem. Sheep laurel (Kalmia angustifolia) is a small shrubby species growing from 3ins. to 6ins. high with a beautiful deep pink bloom, and is often known as sheep poison and wicky. All the laurels, unluckily have dangerous properties, the juices of the leaves being very poisonous and, of course, this plant chooses to grow best on land suitable to sheep, where its tempting leaves often prove fatal to these animals.

From June to the end of July Thalictrum polygonum, the tall meadow rue, revels in stretches of swampy land, drifts of its creamy plume-like flowers waving on stems 7ft. and 8ft. high, while its fern-like foliage, resembling large maiden-hair fern, spreads out many feet around it. The scarlet cardinal flower (Lobelia cardinalis) also grows in moist ground, especially along the sides of brooks during August, and is far healthier than any grown in borders in England, although the temperature is well down below zero in the winter. Oswego tea (Monarda didyma), which we generally call bergamot, also grows in much the same places. Of the three lilies of which I saw most one was the wood lily (Lilium philadelphicum), the blooms being deep orange red and spotted with dark brown at the base. Its name rather leads one astray, as it is more often found in sandy or brush-covered land than in woods. The Turk's cap lily (Lilium superbum) is one of the most prolific bloomers, and has brilliant orange flowers, while the Canada lily (Lilium canadense) likes a nice cool meadow to grow in. There it sometimes can be found in hundreds, a beautiful graceful pale yellow bloom. I saw many of these from the train going down to New York from Rockland, while Bouncing Bet (Saponaria officinalis), which was one of the first foreign flowers introduced into America, has become naturalised and grows in masses along the railroad tracks, filling the air with its delicious scent, with here and there big clumps of the evening primrose (Œnothera biennis) standing 6ft. high. Of the glories of the golden rod (Solidago), which is such an enormous family, comprising nearly a hundred species, it is hard to say enough. From July to the end of September it appeared in dry grass fields, some real dwarf kinds, others having had their heads cut off with the hay, flowered in a stunted state, making the meadows look as if powdered with gold dust. In the woods it outgrew everything else, having enormous stiff heads held 6ft. to 8ft. high, but it was much more happy when growing in swamps, and in several places I saw it with several feet of water up its stem swaying and dipping its golden head in the swift current. The silver rod or white golden rod (Solidago bicolor) is very inferior and is not in any way effective. The pearly everlasting (Anaphalis margaritacea), called by the French "Immortelle," which has a grey-white woolly stem and flowers in flat-topped silvery clusters,

Digitized by Google

covers dry hillsides or recently cleared ground, and has a ghostly appearance and immediately makes one think of some cemetery where all the graves have been newly decorated with this well known flower so beloved by the florists for wreaths, etc.

The golden rods are only outdone in beauty by the asters (Michaelmas daisies). Here we have another numerous tribe, and even more variable in height, colour and form, the shades of colour ranging from white to mauves, lilacs, pinks and damson.

In August and September the most beautiful, to my mind, in its lightness and delicacy of colouring, was lilac starwort (Aster elegans), the most attractive shade of real lilac which, when growing in or near the water, is a large handsome flower, but when on dry dusty ground or hillside is not above 1ft. or 2ft. It grew in between rocks on the mountain sides, it covered the roadsides so that on half-closing one's eyes one seemed to be motoring over lilac-coloured roads.

Never can we in England succeed in having such acres of marvellous autumn herbaceous borders as are to be found in America growing along the roadsides, or such intense colouring and varieties of yellows, mauves and whites, backed here and there by an early turned scarlet maple tree whose colouring is so intense that it would make our cherry trees look quite dingy beside it. We cannot exactly get this natural effect into our gardens, but very many who have swampy ground and ponds might plant thalictrums, golden rods and Michaelmas daisies where they have plenty of room to spread and see how much more lovely they look growing naturally rather than in tied-up bundles, as they are so often to be seen in English herbaceous borders.—EVELYN P. VENNING.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Hyacinths after Flowering (D. J. C.).—The hyacinths should be allowed to mature in the position in which they have flowered, when they may be lifted and dried off in an airy shed or outhouse. It is doubtful, however, if they will flower so well another year, though they may give small spikes of flowers. The single jonquils usually flower in May, and they may be early or late, according to the conditions of the weather. It is getting a little late to sow annuals. Mid-March would have been much more suitable for the majority of such things. Sow the seeds of the perennials at once, preferably in a prepared plot of ground in the open in a rather sheltered place. The resulting seedlings will give good sturdy plants for transplanting in autumn.

ROSE GARDEN.

Paraffin Emulsion for Spraying Roses (C. D. L.).—This can be made as follows; Dissolve one quart of soft soap in two quarts of boiling soft water. Remove from the fire, and while still boiling hot add one pint of paraffin and immediately churn the mixture with a small hand syringe. In five minutes a perfect emulsion will be obtained. For use dilute with ten times its volume of water.

Disease on Scotch Briar (K. L. B.).—The fungus on the briar is the rose rust (spring form), Phragmidium subcorticatum. This spreads by means of the spores on the spring form to the foliage, and produces brown and, later, black spots on the lower side of the leaves. The fungus winters on the leaves, and the more completely they can be destroyed in the autumn the better, for it is from these diseased leaves that the spring infection comes. Spraying with Bordeaux mixture or with a rose red solution of potassium permanganate will help to keep the fungus in check. The disease attacks wild roses, and so makes it difficult to keep in thorough check in the garden.

THE GREENHOUSE.

Injury to Pelargonium Cuttings (S. V. I.).—The pelargonium cutting is attacked by the fungus Botrytis cinerea. This is a very common fungus on all sorts of vegetable matter, and the spores are practically ubiquitous. It attacks living plants as a rule (1) after it has been growing for a time on decaying matter in the soil; (2) When they are very sappy or have some unhealed wounds upon them; and (3) at times when they have been exposed to low temperatures. Some varieties are naturally more liable to attack than others, *e.g.*, the white lily is much more frequently attacked than any other lily by this fungus, which is the cause of the lily disease. Treatment and preventive measures in the present case lie in keeping the plants in as well ventilated a situation as possible, removing and burning all dead and decaying matter, keeping the atmosphere as dry as is consistent with the slow, steady growth of the plants, and occasionally spraying with a solution of 1oz. of potassium sulphide in three gallons of water.

Dividing Clivias (G. C.).—Clivias should be divided as soon as possible after flowering. Turn the plant out of the pot and shake away the soil: this will admit of the roots being separated with as little damage as possible. Break away the offsets and place them singly into pots, using a mixture of two parts fibrous loam to one part of leaf-soil. A liberal proportion of sand should be added to keep the soil porous. It will be an advantage to keep the plants moderately warm and close for a month or two. Give sufficient water to keep the soil moist, and the plants should be sprayed overhead two or three times a day during bright weather. With proper treatment the large plant should flower next year.

TREES AND SHRUBS.

Crataegus prunifolia (K. W.).—This is a small tree up to about 20ft. high forming a rounded head of branches usually wider than high. If not cut off the lower branches reach the ground, forming a beautiful mound of twiggy growths.

Micromeles Folgneri (T. B.).—This is a very ornamental tree allied to the pyruses. It is a native of China, and was introduced to this country about 1901 by Mr. Wilson. Of elegant habit, it has pendent branches which are clothed with silvery leaves and bear flattened heads of white flowers. The small fruits differ from those of pyrus, principally by having no calyx lobes to the apex.

Azaleas not Flowering (P. B. D.).—The Azalea indica shoots sent for examination are too weak to produce flower-buds; moreover, the leaves are very dirty, being infested with thrips. Weak growth may have been caused by the cold, sunless weather of last summer, or the plants may not have been fed sufficiently last year. The reason for the insect attack is probably due to the plants being kept in too dry and too warm an atmosphere. Fumigate the plants with tobacco or one of the commercial nicotine preparations fortnightly for a time, or syringe them with a nicotine solution now and then. Give weak manure-water occasionally while the new growth is being made, providing the plants are not repotted.

MISCELLANEOUS.

How to Catch Mice (J. M.).—Our correspondent should procure a few glass jam jars, those about 7ins. deep and with a narrowing neck or top. Bury the jars in the soil, a few feet apart, and in depth so that the top rim will be level with the soil. Three-parts fill the jars with clean water, and smear some fat—that of mutton for preference—under the narrowing shoulder of the jar, inside and about 2ins. or a little under from the top. The mice are fond of fat and, in trying to reach it inside the jars, overbalance and fall into the water, where they quickly drown. They are voles, or field mice, that do the damage.

Protecting Polyanthuses and Primroses from Sparrows (B. Y. J.).—Our correspondent should make use of a few pieces of glass suspended by a string from small sticks driven into the ground at an angle of 30°, the small pieces of glass being about 6ins. above the plants. Pieces of broken mirror glass are the most effective; these frighten away the birds even when the glass is laid on the soil among the plants. Black thread is usually effective, and Sanitas powder, sparingly used on the flowers, renders the latter distasteful to the birds.

About Ponds, Fish and Mosquitoes (G. H. K.).—All newts found in the pond should be destroyed, if possible. They do worry small gold fish, the latter eventually succumbing to their attacks. Undoubtedly the newts are responsible for the loss of the gold fish. With regard to the mosquitoes the surface of the pond water should be kept as free as possible from scum, weeds or similar foreign matter. If gold fish can be kept they would rid the pond of mosquitoes sooner than any other fish would, or any other means that could be adopted.

Topiary Work (Felsted).—It is not usual to use formal cages in topiary work. Generally beginning with young plants or those of a convenient size, the topiarist by constant clipping gradually obtains the desired shapes. Measuring rods and tapes must be used to secure accurate height and width, but for the most part the operator relies on practice and skill in evolving and maintaining the requisite designs.

Seedlings Unsatisfactory (J. W., Chester).—The very moist soil at the time of sowing would not cause the seeds to fail to germinate in boxes under glass. The best way is to level the soil, water and allow it to drain for a few hours. The seeds should be sown evenly and so covered with fine soil the proper depth for each kind of seed. It is not wise to water the covering soil at the time of sowing. There should be an even temperature and moisture. Recently, the nights have been very cold and, no doubt, that is the reason why our correspondent's seedlings are unsatisfactory. They have been chilled. It was wrong to place the boxes of young vegetables, etc., outside during the daytime, as the change was too great, the air being too cold. Both they and the sweet peas would have fared better in the cold frame, the lights being regulated and mats placed on at night. With the advent of warmer weather the seedlings will make better progress.

Application of Basic Slag (Novice).—Basic slag is a valuable manure, as it supplies lime (which counteracts acidity) and phosphates to the soil in a form which plants can use after a time. But it is slowly soluble only, and must be used only in autumn on that account. We should recommend the sowing of the slag at the rate of, say, 3oz. or 4oz. to the square yard of the surface, just before digging the soil in the autumn. It gives the best results on clay soils, or those containing a good deal of moisture.

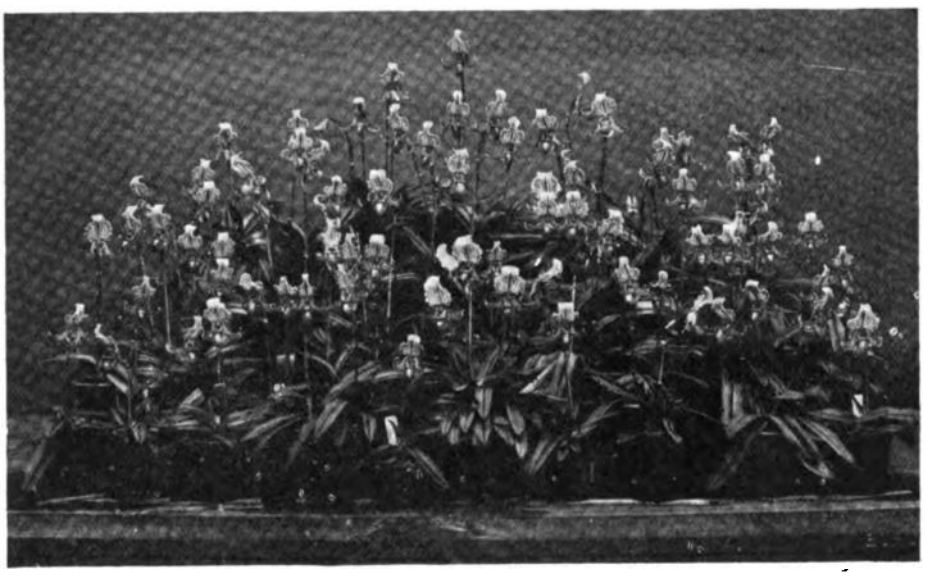
THE CYPRIPEDIUMS

FEW orchids are more easily grown than cypripediums, and for this reason they are admirable plants for an amateur. When visiting different gardens both large and small I have found the popular C. insigne growing under the most diverse conditions, but as a general rule the plants were in good health and annually produced their crop of bloom. The flowers remain in full beauty for several weeks, and as fog resisters they have no equal, a fact that should be noted by all who live in close proximity to large industrial towns.

A beginner could make a pleasing and varied display with varieties of C. insigne alone, if his taste was in that direction, but for preference he should confine himself to the variety known as Sanderæ, the finest of the yellows, and Harefield Hall, the best of the spotted forms. C. Charlesworthi is also good, and the pretty little C. Fairrieanum, also C. Spicerianum and C. villosum. Hybrid cypripediums are almost legion, and here it is difficult to make a selection, but a few stand out above their fellows, and are still held in high esteem by orchid lovers. They embrace Thalia, Leeanum and its varieties Clinkaberryanum, Corona and giganteum, Actæus, Niobe, Priam, Baron Schrœder, and triumphans.

There are a host of others of equal merit, and when an amateur becomes interested he will be anxious to visit a show or nursery and make his own selection.



THE PRETTY LITTLE CYPRIPEDIUM FAIRRIEANUM.

CULTURAL DETAILS.

In many establishments a separate house or division is set apart for cypripediums alone, which, of course, has its advantages, but this is not necessary where only a few plants are grown. Almost any greenhouse will suffice if the temperature during the winter months can be kept at 50° Fahr., with a rise of 5° or 10° by mid-day according to the weather. If sharp frosts exist a slightly lower temperature is better than a lot of fire heat, which renders the atmosphere extremely dry, a condition not conducive to healthy growth, but very favourable for the increase of insect pests. Throughout the greater part of the year a fairly moist atmosphere is necessary, and when the elements are favourable (such as bright, hot days), a light spray overhead once or twice each day will be found beneficial. Blinds will be needed to protect the plants from the direct rays of the sun, and a little ventilation may be given whenever the outside temperature is above 50°, and there is not much wind. Even then the ventilators could be opened an inch or so on the leeward side of the house, the object being to prevent a direct current of air passing over the plants.

REPOTTING THE PLANTS.

When growing cypripediums it should be borne in mind that they enjoy more generous treatment than the majority of orchids, and the better they are treated the finer the flowers. As a general rule a cypripedium will go three years without repotting, providing the soil is right, and it is not over-watered. The compost consists of the best fibrous loam three parts, the remaining portion being made up of Osmunda fibre and partly decayed oak leaves, with just a sprinkling of crushed crocks or sand to keep the whole in a porous condition. With the exception of seedling cypripediums no sphagnum moss need be used. All the fine particles are sifted out, and the plants may be repotted a few weeks after the flowers are cut. Ordinary flower pots are chosen, and these are filled one-fourth of their depth with drainage material. The receptacles should be large enough comfortably to take the roots; the soil is pressed moderately firm and brought up level with the rim of the pot. Small plants may be moved on without any root disturbance, but if necessary large examples may be divided, and each piece given a separate existence, or several may be placed together to form a compact specimen. It should be remembered that only plants of a fair size, and that are well rooted, produce flowers of the best quality. In regard to watering cypripediums an observant cultivator cannot go wrong. Newly potted plants must not be overdone in this direction, but once the roots take possession of the soil they ought never to become really dry at the base. Naturally the greatest quantity is required in the spring and summer months.

T. W. BRISCOE.

THE AUTUMN SNOWFLAKE

FREQUENTLY known as Leucojum autumnale, but also called Acis autumnale, this is one of the most charming of plants.

Surely the Sicilian shepherd, Acis, beloved of Galatea, whose Cyclopean rival, Polyphemus, wreaked vengeance upon him by crushing him under a rock, could have no more fitting memorial than having his name associated with a genus of plants of such exquisite beauty as that to which the subject of this note belongs. It is one of the most exquisite of all bulbous plants which appeal to the lover of miniature flowers, over which he hangs with delight when they are in flower. And this autumn snowflake is undoubtedly one of the most exquisite of these, and is, moreover, the one of its race difficult to obtain in commerce.

If procured in July, too, it will flower the same autumn, and will afford the keenest delight with its delicate chocolate-coloured stems bearing their fascinating drooping flowers of shining white, tinged with pink at the base, about September, and the slender grassy leaves which come after the blooms. I know of no more fairy-like plant in the realm of bulbous flowers, and a group of a dozen or more bulbs on a level part of the rock garden when in bloom affords the keenest delight to all flower-lovers who can appreciate the gems of Flora's treasures in miniature. Unfortunately, there are some cold places where it is hardly safe to plant this autumn snowflake and leave it unprotected in winter until the foliage has ripened naturally, and in some northern gardens the precaution of covering the leaves with glass has had to be adopted. Otherwise it is quite hardy, if planted at a depth of 2ins. or so. A sandy soil and a sheltered sunny place should be chosen for this lovely flower, which came to us from Portugal as far back as 1629.

Patchy and Weedy Lawns

The quickest and cheapest way of renovating impoverished lawns is to dress them with Abol Lawn Sand, at the rate of 4 ozs. to the square yard.

Abol Lawn Sand not only eradicates weeds, daisies and coarse grasses, but it also fertilizes the turf, and improves the colour and texture of the grass.

Trial carton, enough for 5 square yards, 1/4, post free

Sold by Nurserymen, Seedsmen, etc. Sole Proprs. and Mnfrs., Abol Limited, 9, Beltring, Paddock Wood, Kent.

WRITE FOR DESCRIPTIVE FOLDER

Abol

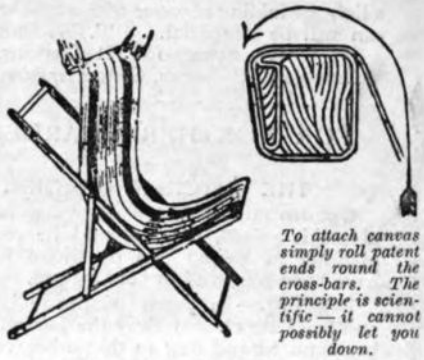
Lawn Sand

Fixed or removed in a moment!



To attach canvas simply roll patent ends round the cross-bars. The principle is scientific — it cannot possibly let you down.

NO MORE DAMP DECK CHAIRS.
Canvas removed or replaced in a couple of seconds.

WILL BE ON VIEW at the BRITISH EMPIRE EXHIBITION, Stand No. T 811 and 811 a/c.

COLLIER'S
Detachable Canvas Deck Chair SEAT 1/6 EACH

COLLIER'S Detachable Chair Canvas (Patent Nos. 187889 and 209572) can be fixed in a couple of seconds to any deck chair frame. For *round railed chairs ask for Model A.* No tacks to tear through the fabric, no trouble. You simply put it there and it stays fixed—safer than the ordinary nailed-on canvas. And for cleaning purposes or reversing the fabric the Collier Chair Canvas is taken off as easily and quickly as it is put on. The pattern being woven right through, both sides are exactly alike.

Stocked by all the Leading Drapery and Furniture Stores and Furnishing Ironmongers.
1/6 1/9, 2/3, and **2/6** each, can also be had in green rot proof canvas.
For list of Local Agents apply to Publicity Manager (Collier's Patent Chair Canvas), Worcester Park, Surrey.

CAN BE ATTACHED WITH EQUAL FACILITY TO METAL RAILS.

A comfortable method for seating large numbers of people for **CRICKET, TENNIS and other CLUBS.**

GARDENERS who treated their garden refuse with ADCO Accelerator last year are now enjoying the fruits of their foresight. They had not to buy in expensive

FARMYARD MANURE

but had a stock of first-class

ORGANIC FERTILIZER

equal to the best stable manure.

A 15/- Bag of ADCO makes 2 tons

of rich plant food. You simply mix ADCO with your green refuse, grass cuttings, dead leaves, etc., as they accumulate. ADCO treats 40 times its weight of refuse.

If your dealer does not stock it, we will send a 1-cwt. bag direct, carriage paid, on receipt of 15/-.

Please mention nearest Goods Station.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Runner Beans.—In every garden runner beans are an important crop, and they repay good cultivation. A trench should be prepared similar to that for celery, with plenty of decayed manure at the bottom, but the top of the trench ought only to be a few inches below the ordinary level. The rows should be at least 6ft. apart, and a distance of 6ins. allowed between the plants. The first and second week in May is a good time to sow the seeds, and when they are coming through the soil a watch should be kept for slugs. A liberal dusting of soot or lime will keep these marauders in check. Prizewinner and Hackwood Park are two useful and reliable kinds.

Vegetable Marrows.—Where no facilities exist for raising plants under glass the seeds may now be sown where it is intended for the plants to fruit. A bottomless box with a piece of glass over the top will form the necessary protection and greatly assist the seeds to germinate. Plants raised a few weeks ago may be planted out in cold frames, and later on the frame may be removed. Admit plenty of air during the day and on mild nights.

Crops in Frames.—At this season the lights may be dispensed with unless there is any likelihood of a frost through the night. Supply the roots with plenty of water, and see that the plants are not overcrowded.

FRUITS UNDER GLASS.

Vines.—Where the vines were started early in the season the berries will soon show signs of ripening, and now it is advisable to look over the bunches for the final thinning. Remove any stoneless berries, and others where they are unduly overcrowded. Continue to stop the lateral growths, and admit air during the forenoon when the weather is favourable for opening the ventilators. The floor and border should be damped down when the house is closed in the afternoon, and the roots kept moist by affording tepid water. A night temperature of 65° Fahr. should be maintained, with a rise of several degrees during the day. In the later houses the bunches will require thinning, and when such work is done the variety of the grape must be taken into consideration. Those with large berries need severe thinning compared with others that are smaller. Gradually tie the shoots down to the wires, and keep a buoyant growing atmosphere by judicious ventilation and damping down. Close the house sufficiently early for the temperature to rise to 85° Fahr. with the sun heat. When the bunches are thinned, feed the roots with diluted liquid manure and some reliable fertiliser.

The Orchard House.—Pot trees should be kept well supplied with water, and when the fruit is set liquid manure afforded in moderation will be beneficial. Where possible, trees producing heavy crops may be top-dressed with rich soil, placing some turfy loam around the edge or rim of the pot. Cherries will probably need thinning, and the growths on all trees should be reduced where necessary. If green or black fly appears, fumigate at once, and afterwards well syringe the trees.

THE FLOWER GARDEN.

Violets.—Owing to the lateness of the season the planting out of the runners has been delayed, but now they ought to be planted without further delay. Select a position shaded from the midday sun, and set the runners 1ft. apart. Until they are established a light sprinkling of water with a rose watering can will be beneficial. T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cucumbers.—Where only one batch of plants is raised, these should be ready for planting in heated pits or where hot-beds have been prepared in cold frames.

Digging.—As crops of broccoli, greens and leeks are cleared away the ground should be manured and dug so that other vegetable plants can be grown thereon.

Kidney Beans.—To have pods ready for picking about the end of July or early in August further sowings should now be made. These plants may be grown on borders or between long lines of green peas. We have found Veitch's Early Favourite a splendid cropping variety.

Onions.—Further plantings of later sown onions should be made on ground that was deeply worked and well manured in the winter and given surface dressings of soot from time to time. The ground should be thoroughly raked, then trodden with the feet or rolled to make firm. The plants raised under glass and brought on in boxes should by now be thoroughly hardened off. They should be set out in lines 12ins. or 15ins. apart according to the space available, and 6ins. or 8ins. allowed between the plants in the lines. If dry weather prevails it may be necessary to water the young plants.

THE FLOWER GARDEN.

Biennials.—Strictly speaking the wallflower is not a biennial, but in gardens it is mostly grown as such. Those who wish to raise young plants should draw out drills 1in. deep and 1ft. apart and sow the seed therein. In seed catalogues there are many fine varieties enumerated. Those who require floriferous plants to carpet beds of spring bulbs should sow seed of forget-me-nots in lines similarly to wallflowers; Perfection Blue is rather a choice variety. Canterbury bell seeds are somewhat small and should be sown in boxes containing medium fine soil and raised under glass.

Chrysanthemums.—Cuttings taken in February and early in March should now be well rooted and sufficiently hardened off to be set out in the borders. Varieties vary in height and those of the Masse type should be grown in the middle or back places of the borders, while the dwarfer kinds such as Craigmillar, Golden Diana and Mytchett White are more suitable to plant near the front, or in small beds.

East Lothian Stocks which have been raised from seed sown last autumn and wintered in cold frames either in boxes or in the soil of the frame, should be set out 6ins. or 8ins. apart in their flowering quarters. The plants should be well watered at the roots a day or two previous to being planted out. Fine double stocks, when well grown, make rather a good show if grouped in masses and each mass all of the same colour.

Lilies of the Valley.—It is often the case that the beds get overgrown and infested with perennial weeds. All that can be done meanwhile is to keep hand weeding until the foliage withers. The whole bed or beds should then be dug up and the roots replanted in a clean sec[illegible] ground.

[illegible] ARMSTRONG
(Gard[illegible] [illegible]lore Nisbett, Esq.),
The [illegible] Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Corydalis thalictrifolia.—This plant is easily raised from seed at this time. It has elegant foliage and yellow flowers, and is a very useful plant for the cool greenhouse or for standing in living-rooms. This corydalis makes a good edging to beds and borders in the conservatory, standing well in semi-shaded places.

Clerodendron ugandense.—This species, with its pretty blue flowers, is easily propagated by means of cuttings, and may be grown as a bush in large pots; but it is seen at its best when planted out and trained up a pillar or rafter in the conservatory. It is also well suited for training on a back wall, and, beyond keeping the shoots thinned out, requires very little pruning.

Jacobinia pauciflora (syn. Gibsonia floribunda).—This is a very old garden plant, which is very useful for flowering during the winter. It is easily propagated by means of cuttings, which root readily in a case with slight bottom heat. It makes a close, well furnished, bushy plant, and grows well in a temperature of about 55° to 60° Fahr. Good plants are produced in one season, but if so desired the old plants can be grown on for several years. If this is done they should be shortened back during early spring and when starting into growth, the plants should be turned out and their balls of soil slightly reduced, so that they can be placed in the same sized pot. When growing freely they should have another shift into suitable sized pots. In the immediate neighbourhood of London this plant suffers very much from fogs, which cause it to drop its leaves and flower buds.

Moschosma riparium.—This beautiful South African plant, with its graceful sprays of small white flowers with black anthers, is very useful for flowering during the winter. If cuttings are inserted at this time, fine large specimens some 3ft. in height can be obtained. The cuttings root readily in a close case with slight bottom heat. The subsequent cultivation presents no difficulty, as it grows well in any good potting compost. During the summer months it grows quite well in an ordinary warm greenhouse. The young plants should be pinched several times, so that well furnished plants are produced. The plants should be potted on as they require it, and really fine specimens can be produced in 8in. pots.

Begonia manicata should be much more generally grown, as it is invaluable for conservatory decoration. Plants raised from cuttings about this time last year, and flowered in 6in. or 7in. pots, should now be transferred to 9in. or 10in. pots. Plants treated in this way should make fine specimens 3ft. or 4ft. in height. The plants, as soon as the flowers show signs of colour, should be removed to an ordinary greenhouse with an average temperature of about 50°. If kept in a warm house the flowers come pale in colour and only last in good condition for a few weeks. Cuttings for a stock of young plants should be inserted at this time, and both the young and old plants grown in a house with an intermediate temperature.

Campanula pyramidalis.—If not already done, seed should now be sown. Young plants in 48-sized pots, and wintered in cold frames, should now have a shift into 6in. or 7in. pots and be stood at the foot of a wall. Plants for flowering this season should now be placed in their flowering pots, which should be 9ins. or 10ins. in size. J. COUTTS.

RHODODENDRONS

AS we are now in the middle of the rhododendron season, it is only fitting that there should be special exhibits of this genus at the fortnightly exhibition of the R.H.S. at Vincent Square. Such being the case, perhaps a few words on this very favourite plant might not be amiss.

I feel rather like the parent who shows off his offspring at the tea-table and then talks to it concisely and thoroughly about bad behaviour once the guests have gone. For rhododendrons have a habit of appearing marvellous when on exhibition, but unless you grow them you never know the heart-burnings and the trials which have to be faced before getting them to grow to perfection. They are inclined to be tricky at the best of times, and in a difficult season like this they are cantankerous to a degree that drives the grower to exasperation. They jib at frost, they jib at drought, they jib at wind, and yet once they have closed in your affection with their hair-like tentacles you are lost. You nurse them like a sick child, and give up golf, home, country and even fishing to their seductions. Even their idiosyncracies have their charm. If they grew like cabbages, half the enthusiasm would go, for there is little amusement to be gained from growing a plant that flourishes like the proverbial bay tree under any treatment you care to give it. The real gardener is only thrilled when there is a battle to be fought and won. He grits his teeth, puts on his thinking cap and wades in. Rhododendrons are fit antagonists.

There is no plant which makes more response to good treatment, particularly in the case of situation and feeding. Half of the failures are due to the former and half to lack of nourishment. As surface-rooting plants they require an unlimited quantity of leaves and rotten wood on which to feed, and this is applied in the form of mulch. The great point to remember, not only with rhododendrons but with all gardening, is to live up to the theory that what is worth growing at all is worth growing well. Rhododendrons are easy plants from which to get some result, but that is not sufficient, they require cultivation, and that takes a little time and a little trouble.

Here are a selection of DON'TS for those who wish to start on the cultivation of this fascinating family:

DON'T grow rhododendrons if you live on a limey soil.

DON'T envy your neighbour if he is successful with a species or hybrid which you cannot grow. The number of species and hybrids in existence is so large that some will be satisfactory for your locality.

DON'T try to grow rhododendrons in situations suitable for annuals or herbaceous plants: they require shade and shelter.

DON'T be disappointed if the flower of a rhododendron which blooms for the first time is not so good as you hoped for. Imagine such a flower multiplied a thousand times.

DON'T grow large-leaved rhododendrons if you live in the north or east: there are many species and hybrids of bush or dwarf form which will satisfy your requirements and are just as lovely as tree rhododendrons.

DON'T imagine that rhododendrons have no personality. They are a widespread race in the northern hemisphere and conditions vary in different countries. It is the duty of a gardener to find out the requirements of a plant. You don't expect a Burman to live all the year round in Yorkshire without special protection or food, then why ignore the requirements of a rhododendron?

DON'T confine yourself to garden hybrids. They are inclined to be too much alike in form and habit. The species and better hybrids vary from dwarfs 2ins. high to giants of 60ft.

DON'T expect a large-growing rhododendron to flower the first year you plant it in your garden.

DON'T expect a rhododendron to grow without care and attention. They require cultivation and food as much as any other plant.

DON'T be alarmed at these don'ts. There are rhododendrons to suit almost every garden. A little care and patience are all that is required.

E. H. M. C.

"THE GARDEN" AT WEMBLEY.

THE GARDEN is represented at "The British Empire Exhibition," and all readers are specially invited to make our Stand a place of call; it is just inside the gate of Harmony of the Palace of Industry, which will be found a very convenient centre. Readers will be afforded an opportunity of looking through, at their leisure, the books produced by *Country Life* on Architecture, Art Furnishing, Gardening, Sport, and many other subjects, such volumes as "Garden Ornament," "Gardens of Italy," as well as smaller practical books, like "The Book of Bungalows" and "Furnishing the House." The Manager in charge of the Stand has instructions to afford THE GARDEN readers every facility and attention, and any information they may require about the Exhibition.

Digitized by Google

CAMPANULAS for the ROCK GARDEN

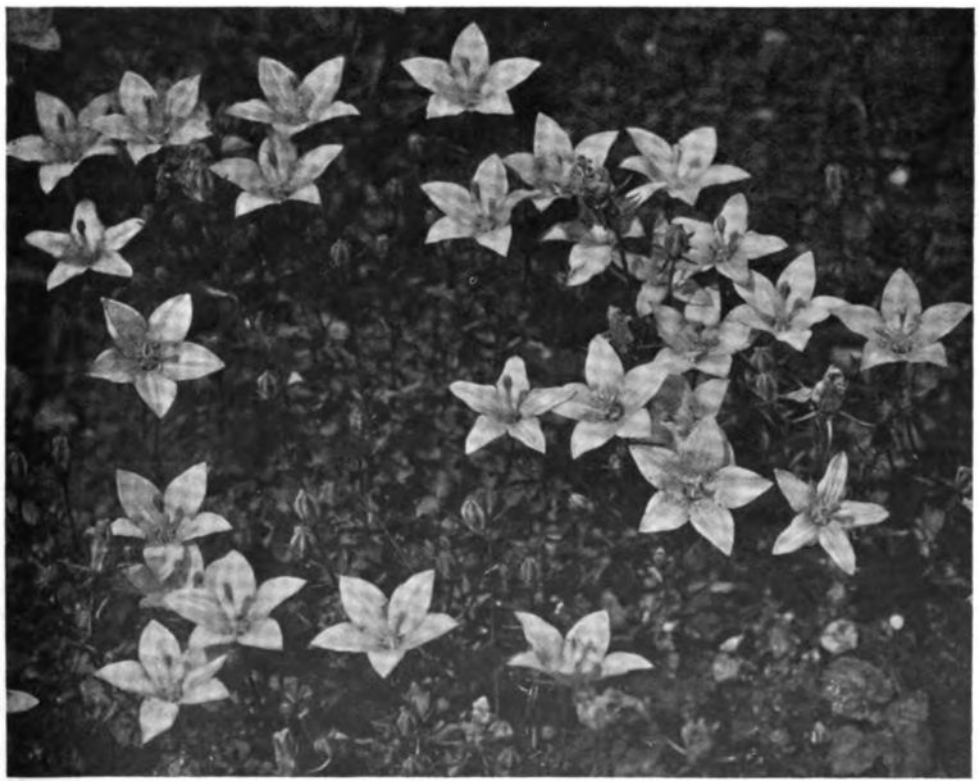
THE campanula family is a very large one, consisting of a number of beautiful plants, many of which are invaluable for the herbaceous border, flower border and wild garden, or for naturalising in the woodland, while a large group are of dwarf habit and compact growth, eminently fitted for use in the rock garden. Many, like CC. garganica, pusilla and Portenschlagiana, are of easy culture, growing in any half-shady positions in moist stony soil; while others, like CC. Allionii, Raineri and Zoysii, require more care and attention. The majority may be accommodated in the ordinary rock garden in pockets and on ledges, provided they are supplied with rich, gritty, well drained soil. The others may be grown under moraine conditions, or in fissures and crevices in the larger rocks, as well as in the joints between them. The campanulas flower generally at a time when the early alpines are over, and thus carry on the succession of bloom for the best part of the summer, large groups of the more easily grown kinds providing a most effective display of colour.

One of the most showy species, and one of the first to come into flower, is C. Allionii (syn. alpestris), which generally blooms at the beginning of May. In the ordinary rock garden soil this plant is not too easy to grow, but in the moraine composed mostly of stone chips with leaf-soil and sand it spreads rapidly by means of its underground runners. In April, from rosettes of somewhat glossy green leaves arise the stalks, about 2ins. high, bearing the buds, which develop into beautiful purple, trumpet-shaped flowers in May, reminding one of a refined Canterbury bell. In colour and in size of the bell it is very variable, there being poor and good forms in cultivation. Many losses in this country are not due to lack of hardiness, but to the depredations of slugs, which are fond of this, as of many other, campanulas. These pests eat out the growing points, and thus cause the death of many promising plants. C. Allionii is easily propagated by division of the underground stems in July, and it can also be raised from seeds, which are produced freely. This plant is found on the Alps of the Dauphiny and Piedmont, growing in heaps of stony debris in full sun. Another choice plant is C. alpina, known as the "Alpine bell-flower." It is nearly allied to C. barbata, but, unlike that plant, C. alpina prefers soil of a calcareous nature. It possesses a fleshy root-stock, and forms a tuft of narrow leaves, from which the stem, only 3ins. or so in height, is produced. The flowers are large and bell-shaped, and vary in colour from pale to deep violet. Each stem bears from six to eight flowers in a raceme in May and June. C. alpina is found at elevations ranging from 6,000ft. to 7,000ft. in the Alps of Austria and Transylvania, among other places, and may be grown in gritty loam. Although perennial in its native habitat, it often behaves like a biennial in this country, dying after flowering. It, however, sets seeds freely and is easily increased in this way.

C. arvatica (syn. C. acutangula) is a charming little species for the moraine. Its habitat is in the Cantabrian Mountains of Northern Spain. Of prostrate habit, the stems are trailing and bear large star-like flowers of a purplish blue colour, while the leaves are small, round and toothed. It flowers in May, and spreads by means of underground stems in the way of C. Allionii. It is quite hardy in well drained, gritty soil in full sun. A favourite in gardens is the well known C. barbata, which is found on most of the mountain chains of Europe, mostly in soil of a non-calcareous nature. The whole plant is hairy, with a tuft of basal leaves, from which arises the stem, about 1ft. high, bearing several large drooping flowers on short stalks. These are pale blue, and bearded inside with long hairs. It is one of the easiest to grow, is a good perennial, and flowers in May and June. There is in cultivation a good white variety, and both are readily raised from seeds. A somewhat difficult plant to grow is C. cenisia, which is found in the glacial moraines and masses of stony debris in the Alps. It is a pretty plant of creeping habit in the way of C. Allionii, with large, wide open flowers of a blue lilac colour produced in May and June. It should be grown in the moraine, in which large stones are embedded, or in a rocky crevice in full sun.

A downy species with silvery grey foliage is C. elatinoides from Lombardy, where it grows in rocky fissures. It does well in the crevices or joints of a sunny wall, sending out simple leafy stems with many dark blue flowers in September. It is very impatient of damp, like the closely allied C. Elatines, which requires identical conditions for successful culture. The latter plant differs in having a branching stem and bears numerous small violet-blue flowers in August and September. Another wall plant is the Italian C. fragilis, of dwarf habit and with branching, pendent shoots. These are clothed with dull green leaves and bear large, wide open, light blue flowers from June onward. One of the most distinct and charming little plants is C. excisa from the Simplon and Alps of Saas, where it grows in heaps of stony debris at an elevation of over 6,000ft. Grown under moraine conditions it spreads freely, running along rocky crevices and between the embedded stones. It has narrow leaves and slender wiry stems which each bear one graceful, drooping, bell-shaped flower of a blue lilac colour. The flower is characterised by having at the base of each lobe of the corolla a hole, as if it had been cut out. This species will not grow in limestone, but a joint or crevice in a rock of non-calcareous nature will suit it admirably. It flowers in June.

An easily grown plant is C. garganica. This species is found in eastern Italy and



A CHARMING LITTLE SPECIES FOR THE MORAINE, CAMPANULA ACUTANGULA.

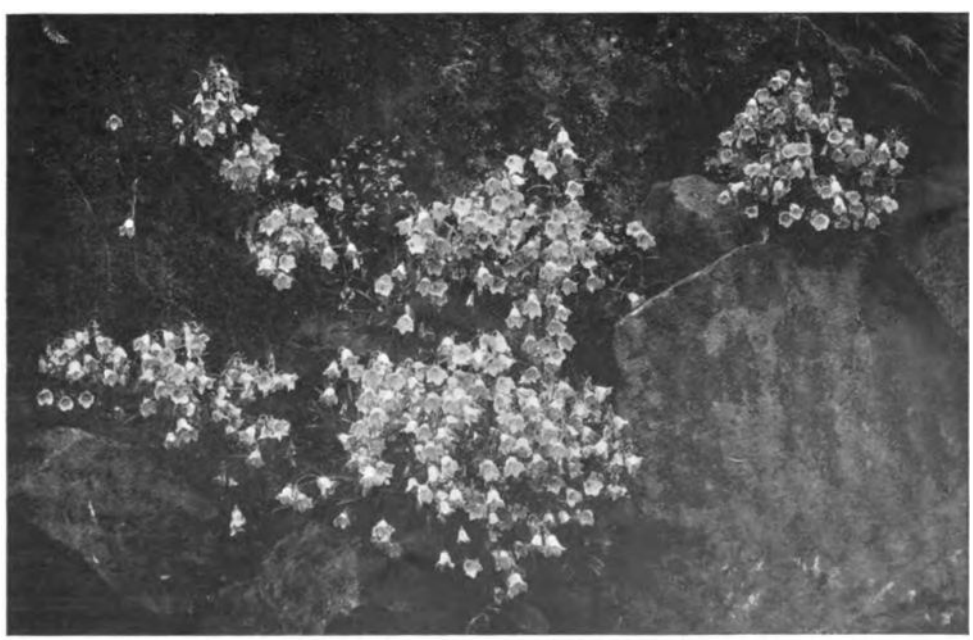
Digitized by Google

Dalmatia, and is one of the most charming of the dwarf kinds. It forms tufts of light green foliage, with many stems clothed with small, rounded, reniform toothed leaves. The light blue flowers are produced very freely from June to August and are of medium size, wide open and looking upward. It grows freely on a sunny ledge in gritty, well drained loamy soil, and is also well adapted for growing in the crevices of sunny walls. It is a very variable species and there are several varieties grown in gardens. C. g. var. hirsuta is a very hairy form which requires a sunny crevice. There are also white forms, and another good variety with large blue flowers having a white centre is known as "W. H. Paine." All may be readily increased by means of division or by cuttings in summer. A very distinct biennial is C. lanata (syn. C. velutina), from the Balkans, where it grows naturally in the fissures of rocks. It makes ornamental rosettes of large grey, silky-hairy leaves, with stout branching stems which bear numerous white, pale yellow or purplish flowers from July onward. It sets seeds in quantity, and self-sown seedlings come up freely in any suitable crevice near the old plant. From the Caucasus we get a very handsome plant in C. mirabilis, with rosettes of shiny green leaves. It is monocarpic, and flowers in two or three years from seed, with a branching stem bearing numerous large bell-shaped flowers of a pale lilac colour in July. It should be grown in a sunny crevice, and prefers limestone.

THE HYBRID CAMPANULA STANSFIELDII. FLOWERS RICH VIOLET PURPLE.

The charming little Dalmatian C. Portenschlagiana (also known as C. muralis) is one of the most useful of the smaller-growing campanulas. Of free-spreading habit in half-shady or sunny positions, this bell-flower will soon cover a good area with its stoloniferous stems, which love to ramble among moisture-holding rocks. In such positions it will produce masses of rich violet flowers from June onwards through the summer months. It varies a good deal, the Bavarian form bearing the largest flowers, and is also more vigorous in habit. It is known as C. P. major. A dwarf tufted plant forming a turf with numerous stolons is C. pulla. It only grows about 3ins. high, with one-flowered stems and drooping, deep violet-coloured flowers in June. This species likes a porous soil rich in humus, but with plenty of small broken stones of a non-calcareous nature. It is a native of the Alps of Austria and Transylvania.

C. pusilla is also known as C. cæspitosa and C. pumila, and is one of the most easily grown. It spreads freely by means of stolons and self-sown seeds, flowering freely from June to October. The flowers are very variable in colour, ranging from rich blue to pale lilac and pure white. There are many named varieties, as well as hybrids of this species. A choice plant is C. Raineri, from the mountains of north-eastern Italy, growing in damp fissures of rocks. It only grows from 2ins. to 3ins. high, with branching stems bearing wide open, violet-blue flowers in July. It is a plant for the moraine or rocky crevice in full sun, in poor gritty soil. C. speciosa is a rare Pyrenean plant in the way of C. alpina, but larger, which spreads by means of underground stolons. From 6ins. to 1ft. high, the stems are stout, branching from the base upward, with large flowers borne singly on long stalks. The blooms vary from light to dark purple, and are produced in June. It grows naturally in limestone cliffs and rocky places in loose stony soil. C. Stansfieldii may be called a large edition of C. Waldsteiniana, and is supposed to be a hybrid between the latter and C. carpatica. The rich violet-purple flowers are borne on thin wiry stems which are clothed with leaves of a yellowish colour. C. Tommasiniana is a pretty species growing about 8ins. high with wiry stems, narrow leaves and light blue or lilac narrow bell-shaped flowers. It comes from the Dolomites and is easily grown on a sunny ledge. Closely allied to this is C. Waldsteiniana only 2ins. in height, with erect stems, silvery grey leaves and pale blue open flowers in June. It is a native of Dalmatia and easily grown in gritty soil. One of the most charming of the family is C. Zoysii, from the Alps of Styria and Transylvania. It grows in the debris of calcareous rocks and is a small tufted species with glabrous



THE ALPINE BELL-FLOWER, CAMPANULA ALPINA.

Digitized by Google

leaves, erect stems 2ins. high, bearing single flowers of rich blue colour. These flowers have a curiously swollen tube and are hairy inside. It may be grown in a moraine, but must be protected from slugs.

There are numerous hybrids in the genus, one of the most interesting being C. kewensis. This came up spontaneously in the rock garden in close proximity to its two parents, C. excisa and C. arvatica. The plant is intermediate in character, having the habit of the former and bearing the open flowers of the latter parent. The wiry branching stems are about 4ins. high, bear narrow sparsely toothed leaves, and produce single flowers on terminal branches. The blooms are rather deeper in colour than those of C. arvatica It is very vigorous in habit and spreads rapidly in stony soil. C. Saxifraga is a fine species from the Caucasus and Armenia. The flowers, which are usually produced in July, are rich violet in colour. It dislikes lime, but thrives in well drained gritty soil.

W. IRVING.

RHODODENDRONS AND AURICULAS AT VINCENT SQUARE

IT is astonishing in this backward season that such a collection of rhododendrons could have been staged at the Royal Horticultural Society's Show of April 29th and 30th at Vincent Square.

RHODODENDRONS.

The chief exhibit of rhododendrons was undoubtedly that of Mr. Lowinsky, who staged a magnificent collection of his famous Don hybrids. These consisted of many vases of cut blooms and about eighteen bushes of flowering plants. It is perhaps unfortunate that not a single plant had a label showing either a name or a number, as it makes description impossible. On the other hand as none of these plants is in commerce this is not such a drawback as it would have been if they were commercially grown. All his blooms showed the fine outstanding trusses of the original Don and what is particularly noticeable is that Mr. Lowinsky is raising flowers of delicate pale mauve of great purity of tone. This is a colour which so far has been uncommon in large-flowered rhododendrons.

Another pale mauve rhododendron with great purity of tone was shown by Messrs. C. B. van Nes under No. 300. We were told that this was a cross between Sir Charles Butler and White Pearl, but the stickiness of the pedicels and the strong sweet scent certainly showed a trace of R. Fortunei. The same firm showed another fine seedling called General Cavendish, large flowers of bright rose and of firm texture. Rhododendrons raised by Messrs. C. B. van Nes are particularly useful in our gardens owing to their extreme hardiness.

Mr. Lionel de Rothschild's exhibit was chiefly noticeable for his lovely form of R. campanulatum, which caused a sensation when shown last year. It is by far the finest form of this species in existence, with flowers of a real mauve. His form of Cornish Cross is also excellent with large flowers opening rich rose fading to a soft pink as they grow older.

Other amateur exhibits were shown by Sir John Ramsden, Mr. Gerald Loder, who showed a very fine spray of R. campylogynum, a fascinating dwarf with mahogany coloured bells, and by the Marquess of Headfort, who showed a series of interesting dwarf rhododendrons in pots.

Messrs. Waterer, Sons and Crisp, besides staging an exhibit of rock plants, had a fine collection of hardy rhododendrons. Their white form of R. punctatum was very charming with its white stamens. Of their hybrids, Alice and Bernard Crisp were the best; they are both fine pinks, but it is a pity that the bad weather was the reason for the poor flowers on the Earl of Athlone, which is one of the very best of the hardy reds. Another hybrid which was unknown to us was Message of Peace, which, as shown, is not up to the usual high standard of this firm; the colour is a poor, washy pink, with a green blotch.

Mr. Reuthe was another exhibitor whose rhododendrons had obviously suffered from the weather. He showed a cross, catawbiense × Thomsoni, a good red with flowers standing well away from the leaves. This should be a useful plant for cold gardens. On his stand were several nice little plants of a good violet dwarf, shown under the name of R. violaceum, although it is doubtful if this rhododendron, of Wilson's collecting, is in cultivation.

Messrs. L. Endtz and Co., staged a fine exhibit of hybrids, among the best being Hugo de Vries, a pink cross, Pink Pearl × Doncaster, Louis Pastem, pink with dark edges and Souvenir de Dr. S. Endtz, which gained an award of merit.

Other exhibits of rhododendrons or azaleas were shown by Messrs. Wallace and Messrs. Rogers. Messrs. Cuthbert showed Azálea mollis seedlings along with lilacs and pyruses.

One of the most charming exhibits was that of Dutch irises and Veronica Hulkeana, shown by the Maytham Gardens. This stand had the real advantage of not being crowded. The irises were shown in white and the veronicas in black bowls, with plenty of space between each plant.

An exhibit that created a great deal of interest and admiration was that from the Hon. Vicary Gibbs of Aldenham. Apart from being a great gardener, Mr. Edwin Beckett knows *how* to arrange his plants. Here were to be seen innumerable alpines, rhododendrons, azaleas, junipers, saxifragas, and primulas. Rocks were employed and such things as Cytisus præcox, Azalea Hinodigiri and maples were interspersed among the other plants. The fragrant Daphne Fioniana (D. neapolitana) and Violas gracilis Black Knight and Clarence Elliott were prominent. We also noted the beautiful Tulipa Clusiana.

DAFFODILS were exceedingly numerous. In the vast collection from Lowdham, Messrs. Pearson and Sons showed Sunset Glow. It is an incomparabilis with a large open red cup with primrose perianth. There were a lot of their well known giant Leedsii's such as Norah Pearson and White Lady.

Messrs. Sutton and Sons had a very tastefully arranged exhibit intermingled with Asparagus Sprengeri.

The Welsh Bulb Fields showed Joker, a giant incomparabilis with a fiery red bowl and yellow perianth. It is somewhat rough but on the whole a fine flower. Here, too, was Jenny Wren, which is a midget Barrii with white perianth.

The Donard Nursery Company's exhibit was good, but too crowded. Here, as in the other exhibits, were many seedlings under number.

On Messrs. Barr's exhibit the beautiful Venetia was again prominent.

Messrs. Bath, Limited, had an exceptionally fine flower in Achievement; it is an incomparabilis. Here too were to be seen Firetail, Red Guard and The Don.

The Rev. G. H. Engleheart sent up a fine lot of Poets. Messrs. H. Chapman, Limited, showed some seedlings, also Silver Salver and one bloom of White Sentinel. Blooms of the latter were shown at Birmingham and there caused a sensation. Mr. W. P. Downes also had a small collection of narcissi.

Mr. R. V. Berkeley sent from Spetchley, Narcissi Spetchley, Sir Francis Drake and Georgina.

Mr. W. F. M. Copeland exhibited some double-flowered narcissi, including Silver Rose. Mr. Baldwin Pinney showed daffodils and violets.

Several exhibits of roses were put up. These were from Messrs. B. R. Cant, Messrs. Frank Cant, Mr. Elisha J. Hicks, Mr. Geo. Prince and the Rev. J. Pemberton.

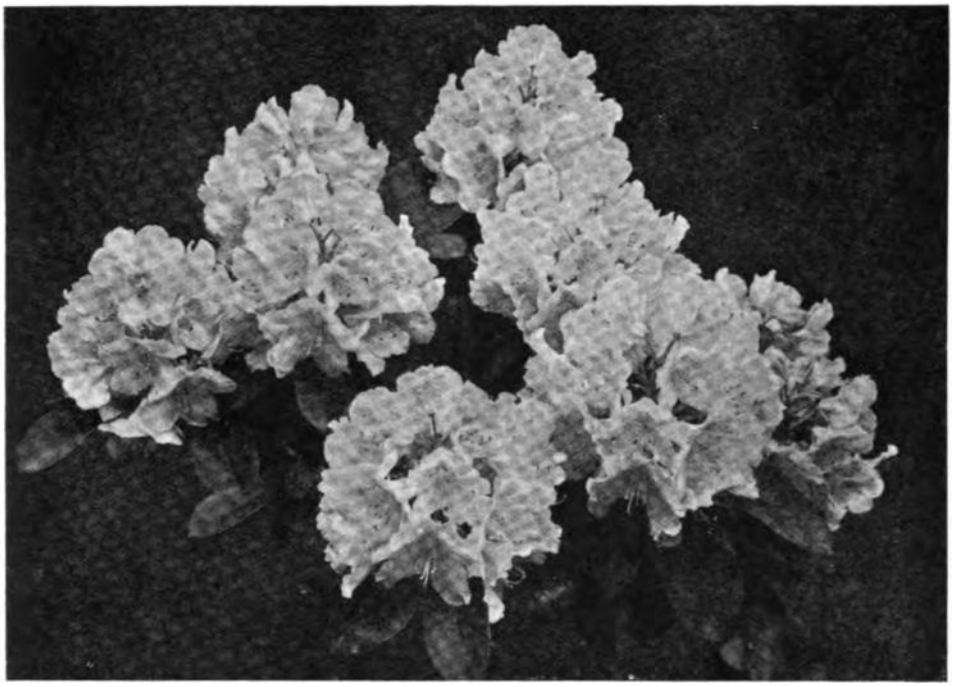
Alpines and other hardy plants were, of course, in great evidence. Mr. F. G. Wood had a fine pan of Campanula Steveni. Here, too, were the brilliant little Verbena chamædrifolia, Viola gracilis alba, his strain of polyanthuses and Mertensia virginica.

St. Brigid anemones were shown by Messrs. Reamsbottom. Alpines and shrubs were exhibited by Mr. G. R. Downer. Violas, aubrietias and æthionemas were shown by Mr. T. Carlile.

Pink seedlings of Primula pulverulenta formed the exhibit put up by Mr. G. H. Dalrymple.

Azaleas and other shrubs were shown by Mr. R. C. Notcutt.

Digitized by Google



THE PINK HYBRID RHODODENDRON HUGO DE VRIES.

Carnations and acacias were again shown by Messrs. Stuart Low Company.

A good lot of Darwin tulips came from Messrs. James Carter and Co.

Messrs. Carter Page and Co. had a varied assortment of alpines and violas.

Schizanthus grandiflorus was shown by Messrs. Godfrey and Son.

Polyanthuses, alpines and the vivid Muscari Heavenly Blue were exhibited by Mr. G. W. Miller.

Messrs. Ladhams showed violas, alpines and shrubs. Pyruses, magnolias, alpines and dahlias were well shown by Messrs. J. Cheal and Sons. Alpines were also shown by Messrs. Maxwell and Beale. Messrs. Tucker and Sons, Messrs. Skelton and Kirby, Messrs. Rogers, Messrs. Pulhams, The Misses Hopkins and Messrs. Bakers. Messrs. Jarman had a fine show of pelargoniums and violas. Polyanthuses comprised the exhibit put up by Mr. J. A. H. Crook.

A large basket of Ficaria gigantea was shown by the Amateurs' Gardening Society, Limited. A good collection of carnations was shown by Messrs. Allwood Bros.

Messrs. Watsons staged Cytisus Dorothy Walpole. Mr. Englemann had a good collection of perpetual-flowering carnations.

PART OF THE ATTRACTIVE EXHIBIT FROM ALDENHAM.

The annual show of the Auricula Society was held in conjunction with the R.H.S. Meeting. Here Mr. Douglas was the principal prize winner and Mr. J. T. Bennett-Poë secured the James Douglas Cup in the amateur's section. Mr. G. W. Miller was also very successful in the nurserymen's classes. Mr. Douglas staged some exceedingly fine plants.

NEW AND RARE PLANTS.

AUBRIETIA GLORIOSA.—A large flowered form with violet flowers of fair quality. Award of merit. Shown by Mr. Maurice Pritchard.

SILENE ACAULIS ELLIOTT'S VARIETY, with soft pink flowers, a charming little plant. Award of merit. Shown by the Hon. Vicary Gibbs.

VIOLA BLACK KNIGHT.—A very fine dark variety with moderate sized flowers of black-purple. Award of merit. Shown by Mr. Thomas Carlile.

RHODODENDRON BRACHYDUM PRIMUM.—A hybrid with long yellow tubes of soft orange yellow. Award of merit. Shown by Mr. J. C. Williams.

RHODODENDRON SOUVENIR DE DR. S. ENDTZ.—A good pink hybrid. Award of merit. Shown by Messrs. Endtz.

HIBBERTIA VOLUBILIS.—A fine climber from New South Wales, with open flat flowers of a good shade of yellow. Award of merit. Shown by Sir William Lawrence.

NARCISSUS DAPHNE.—After several changes we believe the stock is now held by Messrs. Geo. Monro. Daphne is a sport from ornatus. Some flowers are rough, some smooth. First-class certificate for market purposes. Shown by Mr. Geo. Monro.

NARCISSUS WARSPITE.—A fine large incomparabilis with undulating white perianth, large open cup edged red. Award of merit for garden and for cutting. Shown by the Donard Nursery Co.

NARCISSUS ETTRICK.—A beautiful giant Leedsii with deep primrose coronas gradually passing to almost white. Raised by the Brodie of Brodie. Award of merit. Shown by Mr. Herbert Chapman,

NARCISSUS LEMON SQUASH.—A trumpet of a curious pale lemon colour. Shown by Mr. Guy Wilson.

ROSE CLOVELLY.—This rose was described in the report of the National Rose Society's Spring Show on page 285. Award of merit. Shown by Mr. Elisha Hicks.

SCHIZOCODON MACROPHYLLA.—A pink-flowered species. Award of merit. Shown by Mr. G. Reuthe.

PRUNUS SERRULATA KOJINA.—A beautiful white variety with large flowers. Award of merit. Shown by Mr. C. Ingram.

ORCHIDS

FIRST CLASS CERTIFICATES.

Odontioda Ganesa Gerrish's var. Shown by Mr. R. Gerrish.

Cattleya Prince Shimadzu Titanic. Shown by Messrs. Flory and Black.

AWARDS OF MERIT.

Odontioda Joiceyi var. John Cowan. Shown by Mr. J. J. Bolton.

Miltonia Beau Brummell. Shown by Mr. H. T. Pitt.

Odontoglossum Syrinx Var. Helius. Shown by Messrs. J. & A. McBean.

EVERLASTING FLOWERS AND THEIR CULTURE

AMONG the many beautiful flowers grown in our gardens, those known as "everlastings"—or "immortelles," to use a still more old-fashioned term—are worthy of a much larger share of appreciation than is generally accorded to them. Not only do they contribute their full share to the summer and autumn garden, but they eke out the supply of fresh blossoms during the winter months and, when well used, are very different in their effect from the stilted arrangements so common in bygone years.

By "well used," I mean carefully dried, so that the heads stand up stiffly and naturally, and then placed in vases with fresh green leaves that provide a natural setting and thus do away with the barren effect of leafless, shrivelled stems that were such an eyesore in the older arrangements. Nor need there be any monotony, for, after one kind has done duty for a short time, the flowers can be changed for another species: the colour, range and variety in form being so wide that there is no difficulty at all in selecting suitable kinds to harmonise with many different colour schemes.

A GROUP OF "EVERLASTINGS," HELICHRYSUM BRACTEATUM.

Plants that bear "everlasting" flowers fall into two classes—those of perennial nature, such as Gypsophila paniculata, statice, etc., and those of a hardy or half-hardy character. Let us take perennials first, and, of course, gypsophila heads the list, for this is unequalled in its capacity to impart lightness and daintiness to the heavier flowers that are used with it. The best kind of all is the splendid double form—paniculata fl. pl.—that will literally grow anywhere where the soil is light and contains plenty of lime and where the plant receives a generous share of sunlight.

The perennial statices produce their tiny flowers in spreading panicles that are scarcely less useful for "backing up," and latifolia, the Great Sea Lavender, and Wilson's Blue are both varieties that can be cordially recommended. In common with gypsophila, they love a light warm soil and possess similarly thick roots; so that, once planted, they should be left severely alone.

Personally, I appreciate especially the Gladwyn Iris, I. fœtidissima fol. var., the charm of this lying in its splendid seed capsules and the beautiful foliage that associates so charmingly with them. The seed capsules should be left on the plants until they crack and begin to expose the orange-scarlet seeds; then cut and suspend head downwards. Large masses of these, grouped with a few of their own freshly gathered leaves, are splendid for large vases in mid-winter.

Turning to annual flowers, all of those mentioned below are excellent and, at this date, may safely be sown in cold frames (for transplanting) or directly into a sunny border where they are to flower. Acroclinium is obtainable in three varieties—roseum (with yellow disc and rose-coloured florets), album (similar, save that the rays are white) and fl. pl. (a fully double rose form. This is an Australian flower, 1ft. to 18ins. high, with a single flower on each stem, each plant branching freely from the base and bearing a large number of flowers. Ammobium alatum, the Winged Everlasting, bears yellow and white flowers on plants between 1ft. and 2ft. These are produced in succession, so that the plants remain decorative in the border for a considerable time, in addition to their winter value.

The most popular species of all among the annuals is undoubtedly helichrysum, and this should be largely grown, both for the large and handsome flowers and their wide colour range, which opens the door to such an immense field of artistic possibilities in the future. This will give you white, ruby red, violet, scarlet, bronze, mahogany brown, gold, rose, and crimson, and several firms offer the colours separately, so that one may grow exactly what is most required. The peculiar glossy texture of the petals adds not a little to the brilliance and intensity of the colour. The largest and finest strain is that known as monstrosum, in which the flowers are of giant size. The plants branch freely, flower profusely and reach a height of 2½ft. to 3ft. A dwarfer strain, more suitable for small gardens, is nanum, in which the colour range is equally wide, though the plants do not exceed 18ins. Sunlight is life to them, and the warmer and sunnier the border the better the results will be. Helichrysums are not such rapid growers as most of these annual everlastings, and the best results are obtained when sowing is done in March, in boxes in a warm greenhouse, although splendid results may still be obtained by sowing under a cold frame that, when the plants are well up, is lifted off bodily, thus leaving the plants standing in the open air.

Rhodanthe maculatum is obtainable in four varieties: carmine with yellow centre, double carmine, white with yellow centre, and double white. All of these are simply exquisite, very distinct and among the most beautiful of all everlasting flowers. The crinkling papery petals rustle with a most attractive sound at the least breath of wind, and it makes a very striking pot plant, in addition to its value in the open border. The growth is very rapid, and the plants flower with extreme freedom. Although they reach a height of 1ft., the growth is so slender that they require but little space, and 3ins. from plant to plant is ample. Everyone is familiar with the masses of Statice Bonduelli and their handsome pale yellow sprays, so common on the trays of the street hawkers in summer. This is another very easy half-hardy species, but needs to be sown early and in heat to ensure success. The mauve and pink Statice sinuata is hardier and may still be sown in the open border for late flowering. Waitzia aurea grows about 18ins. in height and bears masses of golden yellow flowers in late summer and autumn. Xeranthemum—the true Immortelle—is very popular and may be obtained either in mixture or in double white and rose, while there is also a violet form known as imperialis. This may be sown outside now, and should give an excellent account of itself.

With all varieties, successful drying is an important item, and upon this depends much of their utility for winter decoration. The flowers should never be allowed to become fully expanded upon the plants themselves, a remark which applies with special force to the double forms. Just when the outer petals begin to show signs of unfolding is the correct time, and a good length of the stem should be taken.

H. W. CANNING-WRIGHT.

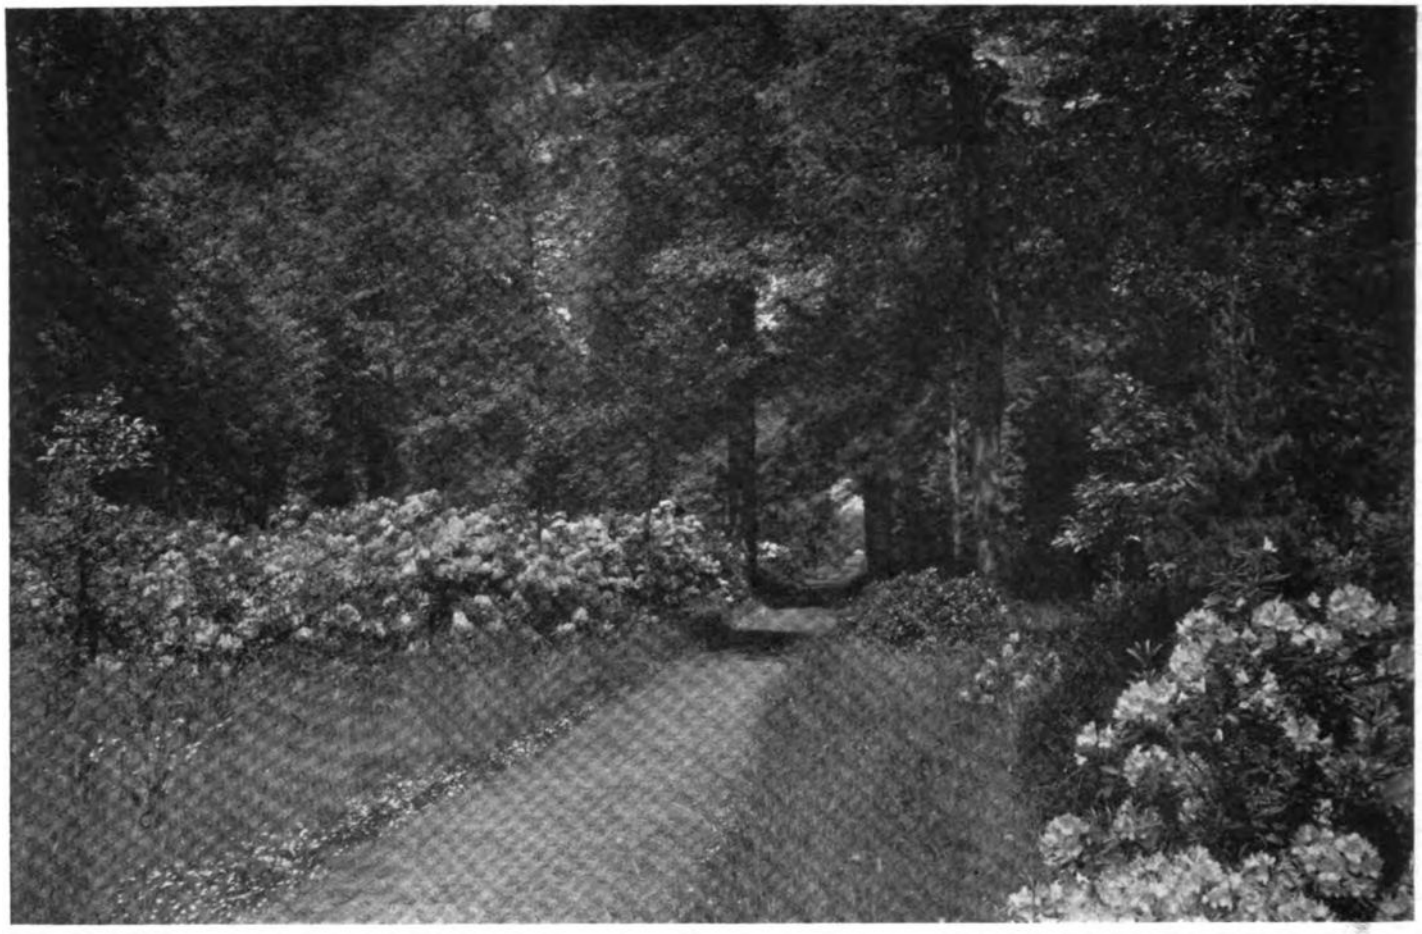
THE GARDENS AT ALDENHAM



THE RHODODENDRON WALK AT ALDENHAM.

NEARLY two thousand years ago there came to the shores of the "Western Isles" a large party of adventurers, in the form of the invading Roman legions, under Julius Cæsar, and an evidence of their occupation and activities, in the shape of the old North Road, now named Watling Street, running from their camp at Londinium (London) to the one at Verulam (St. Albans) still exists. The travellers of those early days, having topped the long rise of the road from their camp by the river, reached, at a point about midway between the two places, the commencement of a stretch of what was undoubtedly undulating forest country. Now, again, adventurers from all parts of the world—a different world from that known by the Romans, and one that fulfils the legendary Druidical prophecy to Boadicea, Queen of the Iceni, immortalised by the poet in the words "Regions Cæsar never knew, thy posterity shall sway"—are journeying to Britain.

The scene along the old North Road has, however, changed, and at the top of the rise from the village of Elstree (twelve miles direct from the Marble Arch) a long stretch of fairly open country meets the eye, and situated at the beginning of it lies the estate of Aldenham Park, owned by Lord Aldenham, in the gardens of which has been gathered together through the activities of the resident, his brother, the Hon. Vicary Gibbs, the most wonderful private collection of hardy trees and shrubs in the world.

Visitors from the Colonies and other places abroad who are making their way to the Wembley Exhibition will, on reaching the Exhibition grounds, be at a point roughly about six miles in a cross-country line from these world-famous gardens. It was only about thirty years ago when a real and comprehensive start was made on the collection, and yet in that space of time an air of permanence has been imparted to the gardens such as one would hardly expect to be attained in double that period. In them are set out in most attractive fashion the treasures gleaned from practically every country and clime of the globe. Thousands of fine specimens are to be seen, and the introductions of intrepid explorers like Messrs. E. H. Wilson, R. Farrer, G. Forrest, etc., from the almost unknown regions of China, are to be found growing happily side by side with plants from Canada, America (through the United States, Mexico and the southern portion of that great continent), Europe, Africa, Australia, New Zealand, India and other parts of Asia; and, from wherever our visitors in this year of grace, 1924, may travel, they can probably find a number of plants reminiscent of their own location beyond the Four Seas.

For examples, in one spot two large specimens of the eucalyptus (cider tree) of Tasmania and South Australia rear their heads; near by can be seen a large bush of Hymenanthera crassifolia from New Zealand, and an Amelanchier canadensis of the Canadian regions in close proximity. American visitors would be interested in the wonderful collection of the beautiful American cratægus, of which Aldenham possesses about seven hundred species and varieties grouped together. So the tale of the collection runs on; and, besides the hard-wooded forms

Digitized by Google

of plant life, there is also a very big collection of alpine and rock plants; while two of the greatest attractions of the gardens are the large collection of Michaelmas daisies, the majority of which were raised at Aldenham (they number somewhere about 150 distinct varieties), and the enormous collection of phloxes (so lovely in July and August), mostly, again, Aldenham-raised.

Fine examples of avenue planting are to be seen in various directions, full use of this interesting feature having been made, and a variety of subjects chosen for the work, such as oak, elm, lime, maple, birch, etc. The water gardens, through which runs a stream, set in, after most careful thought, a region that was originally a quiet grass paddock but is now a most ornamental quarter, with its carefully planted shrubberies, through which the stream wends its way to the bathing pool and the moats. The latter, appertaining to the original residence of old times, were allowed to silt and fill in, but the late Lord Aldenham had them excavated and placed into good order, and they are now a most pleasant feature, their edges planted with suitable subjects, and their waters carrying their burden of aquatic plants, as does also the ornamental water in another direction, known as the Wrestler's Pond.

Much care and attention have been paid in recent years to the grouping of plant families, and among those so dealt with are the bamboos—which have a large garden devoted to their culture — the oaks, flowering crabs, American thorns, elms and the yews, of which latter group there is a most complete collection of known species and varieties. Berberis, too, have been grouped, and of this family there are to be seen no fewer than 160 species and varieties under name, and about another sixty or seventy so modern of introduction that they are still under the collectors' numbers, not yet having been determined for nomenclature. The oaks, just mentioned, form a group from various parts of the world, just on 200 strong in species and varieties. This will give a little idea of what the Aldenham collection is like, it being roughly estimated that there are now something between 8,000 and 10,000 species,

ONE OF THE LILY POOLS, WHICH IS SET TO ADVANTAGE WITH A BACKGROUND OF FINE TREES.

A FINE TREE OF CORNUS CONTROVERSA.

varieties and forms, including a certain number of florists' varieties, of trees and shrubs alone, an enormous number, the size of which is due in a large measure to the really extraordinary number of new introductions in the past ten to fifteen years, sent home by those wonderful collectors in China.

Long vistas, too, exist through the woodland portions, to which every care and attention have been given, and the journey through this part, on round the lake in the park, etc., easily fills a long day, until the visitor comes to the conclusion that, probably, it would have been better to select a month to wander round in order to see all the many attractions of Aldenham.

No notes on these gardens would be complete without reference to the vegetables grown there, for which, again, Aldenham and the name of the head-gardener (Mr. E. Beckett) are almost synonymous terms in the horticultural world, the highest awards at the large exhibitions all over the British Islands having been gained by the edible produce of Aldenham.

A PERSPECTIVE VIEW OF THE GARDENS.

A great success, considering that the soil of the estate consists of heavy London clay There are a large number of really fine trained fruit trees on walls at Aldenham, which illustrate this very useful mode of culture.

The gardens, thanks to the courtesy and kindness of the Hon. Vicary Gibbs, are opened to the public on each Saturday afternoon during the months of July, August and September, and the whole of August Bank Holiday, and many hundreds of visitors avail themselves of the privilege. Further than this, special permission, upon application being made, is invariably granted to the keen student and enthusiast in matters horticultural, for Mr. Gibbs is always most pleased for plant lovers to see his efforts. In view of the many visitors from abroad that will be attracted to this country this year owing to the Empire Exhibition at Wembley, through the kindness of the Hon. Vicary Gibbs we shall be glad to make arrangements for visitors who may be unable to visit the gardens on the public days to have a chance of viewing this famous garden. For many years past there have been numbers of visitors from the Colonies and other places abroad to Aldenham, and they have spread the fame of these gardens far and wide upon their return to their native habitats.

THE MIDLAND DAFFODIL SHOW

BY THE REV. JOSEPH JACOB.

TO my great regret I was unable to get to London this year to pay my respects to Mistress Daffodil. There were great searchings of heart among those who were responsible for her court in Vincent Square as to what would happen after the cold and unpropitious March, but the S.O.S. call was heard in Ireland and Cornwall, and in one or two other climate-favoured spots in the South, with the result that there was a goodly muster of bloom on April 15th, of which I am told the outstanding features were the splendid shapely perianths with which Mr. P. D. Williams had surrounded his red cups.

At our informal meeting after our daffodil dinner at Birmingham, someone asked "What are raisers of seedlings trying to get?" No doubt, for one thing, better perianths for our red cups and bowls. However the association of these coloured coronas with wild, untamed perianths may tickle the fancy of the "market men" and the arrangers of cut flowers in vases, they are blemishes when compared with the ideal flower which, at present, has no more substantial existence than in the fond imagination of the daffodil "curious."

This untoward spring showed its sinister influence at Birmingham. "Poets" were as infrequent in the competitive classes as currants in a penny bun; and there were no flowers from our time-honoured supporter, Mr. Joseph Mallender, and no group—not one bloom even—from our prehistoric supporters, the Pearsons of Lowdham: for long before there was a Midland Society they had got into the way of exhibiting daffodils at Birmingham (page 10 of the Annual Report for 1908). They began in 1893, but the Midland Society did not come into being until 1899.

If the season was unpropitious, the weather on the two days of the Show (April 24th and 25th), was just about right—dull, with but little sun, and fairly warm. Our venue is the big range of glass at the Botanical Gardens at Edgbaston, so it will be readily understood that a blazing sun is, in more ways than one, not exactly what the blooms relish. Their complexions suffer. Delicate refinements and grades of colouring are obliterated in strong sunlight, and too much heat promotes too much perspiration, which soon exhausts the old blooms and damages the new.

"Where they do agree on the stage, their unanimity is wonderful."

I had many misgivings. The first item in the 1924 Schedule was "The Leamington Cup" for "*the best flower in the Show*," to be judged by the Floral Committee. "Now," I said to myself, "we are in for it"; but *mirabile dictu*, when it fell to my lot to put the motion that "The Cup be given to the flower marked 22LY in the first prize group of the Bourne Cup Class," ten out of the eleven of us voted for it. 22LY is now Rewa. Dr. Lower of Presteigne, its raiser and exhibitor, thus named it for the sake of his old association with a ship of this name as ship's surgeon. It is a flower with a perfect perianth—pure white, smooth and with that "good" look which we know so well in other things. It has a large cup of Bernardino colouring suffused with and edged by a narrow band of pale orange. It carries itself well. In a word, it is a grand flower. I did not measure it, but it would probably have a diameter of about 3¼ins. to 3½ins.

"WHEN DOCTORS DIFFER."

It fell to me to be one of the judges of the "single bloom" classes. Immediately we started on the yellow trumpets I found that my yoke-fellow and I were as far apart as the poles in our ideas of what we were to look for in the flowers. Was it to be their suitabliity for garden decoration, or their excellence on the show tiers? The Royal Horticultural Society has acknowledged that there is a distinction by the regulations of its Floral Committee as to the granting of awards. The standpoint of all judges at a daffodil *show* surely ought to be that of the "show." This point is not sufficiently considered by those who act in that capacity. The question, in the special case to which I have referred, was: Should the first prize go to a large but somewhat rough variety, Golden Harvest, or to an exquisitely refined flower which, I found after judging, was staged by Dr. Lower? In the beautiful smoothness and quality of its perianth it was reminiscent of his Royalist, which Mr. Guy Wilson has described as "the most perfect show yellow Ajax yet seen." I may add that two experts whom we called in and by whose decision we agreed to abide, with one consent put Dr. Lower's flower first.

GROUPS.

There were eight non-competitive groups of various sizes. Of these the Donard Nursery Co. and Messrs. Barr and Sons received gold medals. Mr. J. L. Richardson gained a silver-gilt; Messrs. Bath, W. F. M. Copeland, Cartwright and Goodwin, and Guy L. Wilson, had silver medals; and Messrs. Hewitt and Co. a bronze.

As may be imagined, these helped the show very much. There were no end of good things for the public to see and buy. However, as the end of these displays is to sell to visitors, I sometimes feel that if a fair proportion of quite cheap varieties were included it might be a better bait than having nearly all expensive ones. The ordinary public do not want to start with a Royalist at £18 a bulb, when they can get an Emperor for 3d.

THE REPORTERS' TRIALS.

How many exhibits were staged for the big—that is the swagger—classes at the London Show, I do not know. We Birmingham folk are not a little proud of the number that were staged at ours. There were six groups staged for the Bourne Cup, which was won by Dr. Lower; five were staged for the Cartwright Cup, also won by Dr. Lower; and six lots of six blooms each for the White Daffodil Trophy, which was won by Mr. Guy L. Wilson. These entries mean that the Doctor and Mr. Wilson had to fight hard for their honours and that there was a fine display of the very best and newest varieties to be seen. Yes! to be seen, but not described. Such a very large proportion of the very "latest out" are shown under numbers or letters—not names. Time and again I have said I must "do" that, only to find that "that" was 2XW or some such combination, and I do not think for several reasons it is any good giving such a one a detailed description. It is unfortunate that it is so and I can only ask you to take it from me that in the three above mentioned classes, together with the smaller ones, Seedlings and New Varieties, there were many fine blooms. Could not all blooms in competitive classes be named?

I hope, in the next issue, with the Editor's permission, to say something about ten or a dozen varieties that caught my eye.

NEW DAFFODILS.

TENEDOS comes first as it received a first-class certificate. It is in every sense of the word a "great" flower. It was raised by Mr. Engleheart, and I have read that the Brodie of Brodie considers it one of the plums of his unique collection. The flower has a diameter of at least 5ins. when well grown, a rather long straight-shaped cup which opens a primrose yellow, as one would expect on looking at the bottom of the corona. The perianth segments are narrow and pointed, and so are a break-away from the old orthodoxy.

BEERSHEBA.—A white trumpet variety raised by Mr. Engleheart from White Knight, but, unlike that variety or any of the older groups of whites, it has a good stem. It has a diameter of 4½ins. and the purity of the flower is very remarkable. The perianth is placed at right angles to the corona and has pointed segments. Will this be one of the flowers along with White Lady that will hand the name of Engleheart down to future generations?

WHITE NILE.—A giant Leedsii, raised by the Brodie of Brodie. The delicious green base as you look down the corona proclaims its whiteness. Its flat, good looking perianth proclaims its high quality, even if it is but 3½ins. to 3¾ins. in diameter. I am coming to the opinion that a daffodil may be too big, even if it has all its members in proper proportion and is also of good quality. "You are wrong," said a man who has an eye on the mercenary side of seedling raising, "You cannot have a flower too big for the market." Well! well!

MASTER ROBERT is a large, smooth, rich yellow trumpet variety with a wide bold edge to the corona and a diameter of 4⅝ins. It is a good variety, but hardly a Grand National winner.

MOIRA O'NEILL.—A very pale bicolor trumpet. The perianth is flat and shapely and has a diameter of 4½ins. The bold recurved top of the pale lemon corona gives the flower a stately and important look.

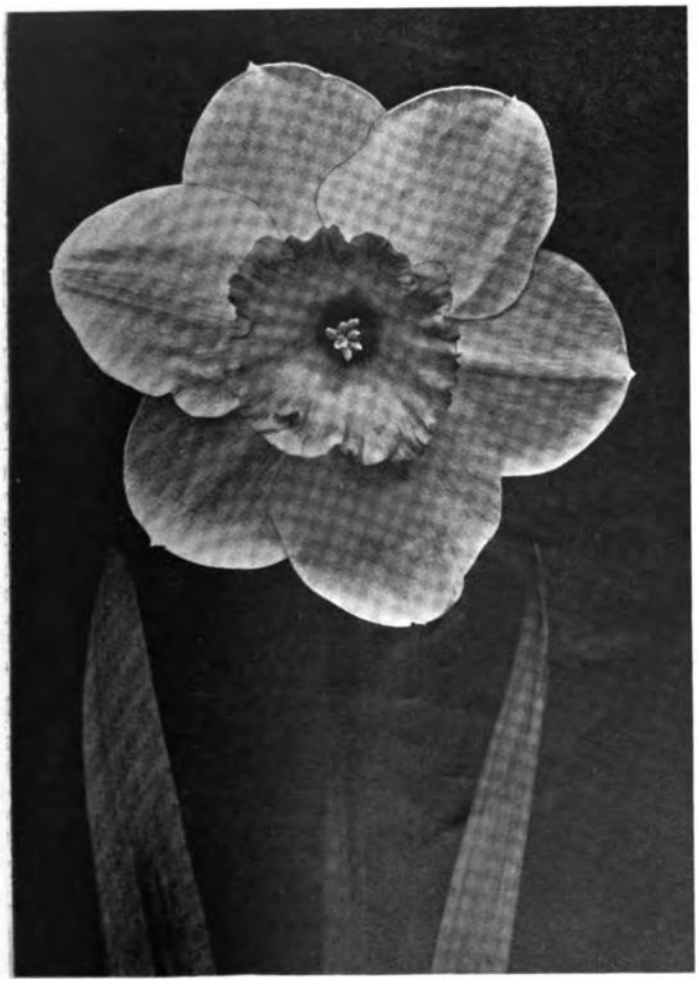
CRUCIBLE.—This is a white perianthed Barrii. The flat cup has a wide red edge. As a whole the flower has a peculiarly fresh and clean look.

CICELY.—A giant Leedsii with a narrow long corona and a clean cut perianth with pointed segments. It should make a good garden plant and be useful for showing, as it is out of the ordinary in its general appearance. It was sent by Mr. Alex. M. Wilson and was a pleasant reminder that he is still able to get about his daffodils. I am so glad.

MAGICIAN.—The large flat orange red corona is the striking feature of Magician. This has a diameter of 1½ins. and superposed as it is on a pure white somewhat reflexing perianth made a flower which fully earned its award.

GOLDEN HARVEST.—A Dutchman that gained a F.C.C. at Haarlem in 1923. It is a rich yellow trumpet and ought to make a good garden plant.

IRENE COPELAND.—One, of course, of Mr. W. F. M. Copeland's raising. A very full flower of many white segments with pale maize snippets among them. it is reminiscent of Parkinson's picture of "John Tradescants great Rose Daffodil." Mr. Copeland is very bucked up after the London Show. He thinks "doubles" are coming to the front.



JUDGED TO BE THE BEST FLOWER IN THE SHOW – NARCISSUS REWA.

THE ROYAL GARDENS, KEW.

His Majesty's Stationery Office has just published an illustrated guide to the Royal Botanic Gardens, Kew. It is an excellent little booklet and should prove of inestimable value to visitors to the Gardens. In addition to some excellent views of the Gardens, a map is included which should be quite easy to follow. The guide is obtainable at the Gardens and the price is 1s.

For the first time since the war no charge is being made for admission, except on students' days (Tuesdays and Fridays), when 6d. is charged. The Gardens, which are about 300 acres in extent, are easily reached from all parts of London. There will be a great influx of tourists from abroad for the purpose of visiting the Wembley Exhibition, and they should not fail to make a pilgrimage to Kew. The hours of admission are from 10 a.m. till dusk, which allows plenty of time for examination of plants.

THE EFFECTS OF WINTER ON A WEST SOMERSET GARDEN

BY N. G. HADDEN.

A WINTER which begins in November and goes on well into April is so uncommon an occurrence in the usually genial West Country that some notes on its effect on some of the more tender plants may be worth mentioning. Although no very severe frost has been recorded (not more than 10° Fahr. on the screen), several degrees night after night, accompanied by bitter winds, soon make many plants look unhappy. The excessive rainfall of the early part of the winter rendered young shoots tender and little able to resist frost, while it also caused a heavy casualty list among the mesembryanthemums and other delicate succulents. On the whole, however, there have been surprisingly few plants killed outright, though many have been either cut to the ground or badly browned. All fuchsias have suffered considerably, all the choicer species (*e.g.*, Cottinghamii, venusta, cordifolia and even macrostemma conica) are killed down to ground level, but are gradually breaking from the base now. The two New Zealand fuchsias (F. excorticata and the little F. procumbens) have escaped damage—the former species, indeed, is already hanging its flower buds from the almost leafless twigs. Calceolaria violacea looks sad, all last season's growth being killed, so that we cannot expect to enjoy many of its quaint little gaping mouthed flowers this year. C. alba has come through better than I dared hope, though I have only a small plant with little hard wood as yet: it is such a distinct and refined species that it is curious it is so seldom grown, even under glass. Its small white flowers are exceedingly attractive, even if they are formed uncommonly like a tiny human skull! The strong-growing C. integrifolia stands a lot of frost when once it has made hard wood, and is then a very handsome little shrub with masses of yellow flowers. Clematis indivisa on a south wall is looking quite happy and its large flowers are already beginning to expand and change from green to white. It has only been planted out for two winters, but has already run up above the wall and is rambling through the branches of an old ivy which gives it welcome shelter. C. calycina has been flowering steadily since the New Year, but it is not sufficiently showy to appeal to most people, despite the beauty of its fern-like bronzy foliage. Like most of the wild clematis species, it requires a good deal of space to show itself to advantage; it is more suited for climbing over some worthless tree than for precious wall space.

Cestrum (Habrothamnus) elegans has lost all its leaves but is now breaking to the very tips of the branches; this was planted out two years ago from a small pot, and is now a fine shrub 8ft. high. Its large trusses of ruby red flowers are so freely borne over so long a period that it is a magnificent plant for districts where it will succeed outdoors. I should like to try the orange C. aurantiacum outdoors also, but fear it is less hardy and more difficult to obtain.

Bowkeria triphylla has had the tips of its shoots nipped by east winds, but is otherwise uninjured; it is interesting as being one of the very few South African shrubs that are at all hardy in English gardens. Its flowers are like white calceolarias, but they are not very freely produced till the plant is a fair size—luckily, it grows rapidly.

On a wall facing east, but given the shelter of a wattle hurdle in severe weather, it is good to find a young plant of Tecoma jasminoides looking full of health and vigour. Alongside it is a plant of Cantua buxifolia, which has shed a good many leaves and certainly hates cold winters; it is a quick grower, but does not appear to flower very freely while young. The buds are liable to drop off if they are formed too early in spring, so a check to their development may prove a blessing in disguise; the beautiful rosy tubular flowers are not unlike those of Abelia floribunda on a larger scale. Just beginning to send its thread-like twining shoots among the twiggy branches of the cantua, Sollya Drummondii has come through the perils of winter unscathed; this plant was only put out last autumn, but it appears as though it may prove as satisfactory a doer as the more familiar S. heterophylla. The flowers of S. Drummondii are smaller but of a much more intense blue, comparable, indeed, to Gentiana verna, while they hang from almost invisible foot-stalks. Another Australian climber which appears unhurt is Kennedya Comptoniana, but this is still a very small piece, and I have not yet seen its large purple pea-flowers. The South American "blue pea" (Lathyrus pubescens) has come through perfectly, planted against an east wall, and has proved itself a most satisfactory plant in every respect, quite the best of the perennial peas that I know. The flowers are of a particularly attractive shade of lavender-blue—nearer blue than anything in sweet peas, but not the true blue of the little annual chickling pea.

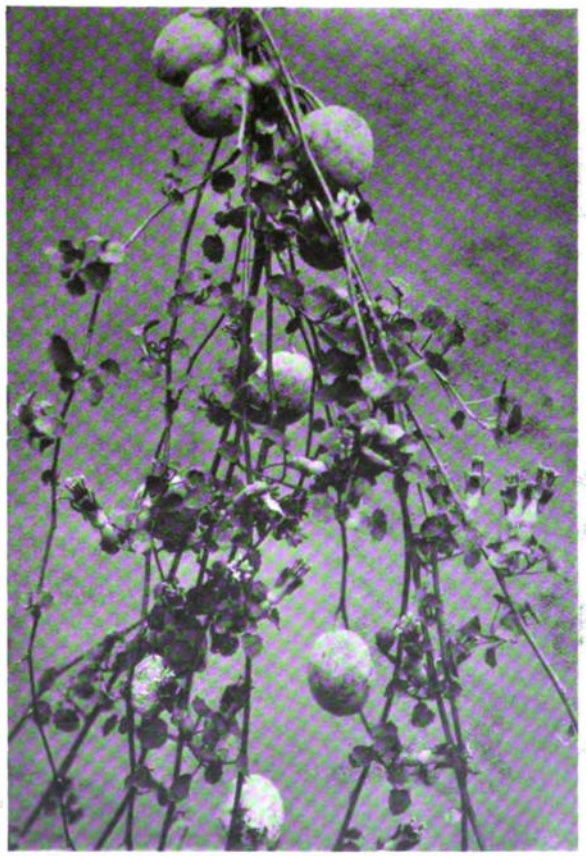
Leonotis Leonurus looks about as dead as Queen Anne, but there is still hope that it will come from the base. Last winter it scarcely shed a leaf, and is well worth a trial in mild districts for the sake of its whorls of gorgeous orange-red salvia-flowers which come late in the autumn. Beside it is a small plant of Lagerstrœmia indica, which only arrived here from Japan fourteen months ago; it foolishly continued to make young growth so late that the November frosts cut them back very severely. Still, the plant is quite alive and will soon come into leaf again; its rosy blossoms come in profusion in late autumn, but only if the wood has been thoroughly ripened by a hot summer.

I am watching a 5ft. high Buddleia Farreri with great interest; it has not suffered from the winter, but I do not know yet if it is going to flower. The great "grey flannel" leaves are so distinct that it seems worth growing for their sake alone, but I should like to have the flowers as well.

Buddleia auriculata is, as usual, quite uninjured: in fact, it makes such rampant growth in these parts that it has to be drastically restrained from smothering its neighbours.

I have never seen B. asiatica in the open in England, but it is reported to grow in Cornwall; it is quite distinct from B. auriculata, though frequently confused with it.

Acacia falcata (a home-raised seedling now about 10ft. high) is a mass of bud and has once more proved itself the



THE NEW ZEALAND FUCHSIA PROCUMBENS HAS ESCAPED DAMAGE.

Digitized by Google

hardiest species grown in this district. The delicate foliage of A. dealbata is much more easily damaged by wind, though the plants flower abundantly when well sheltered. Small plants of A. armata, screened from the east by other shrubs, are laden with buds, but others in a more exposed position are badly browned. A. Baileyana is unharmed, but my plants are too young to flower as yet. Cordyline australis of various ages are all untouched, but some two year old seedlings of C. indivisa (the broad-leaved form) are slightly nipped.

Prostanthera rotundifolia has come through the trials of the long winter nobly; for the first two or three seasons here the young plants were badly cut by slight frosts, but now they appear to have become acclimatised and are already becoming transformed into 8ft. pyramids of violet blossoms. I am pleased to read that this fine shrub has recently received public recognition, though doubtless the specimens sent from Kew to the Royal Horticultural Society's Show were grown under glass.

Perhaps our greatest disappointment this spring has been Viburnum Carlesii, which had set over forty flower buds in the early winter, but every one went blind. I do not know whether to cast the blame on the frosts or the rains or the Evil Eye; anyhow, the plant seems in robust health, and its foliage is developing rapidly. The newer V. fragrans is too small a plant to flower here yet, but if it lives up to its reputation of being superior to V. Carlesii it must, indeed, be a precious treasure.

The evergreen V. odoratissimum (Awafuki) has suffered slightly from cold winds, but will soon recover when more genial weather comes along. V. tomentosum Mariesii and plicatum are well laden with buds; and all lilacs, deutzias and philadelphuses (even young plants of P. Falconeri) afford a similar promise of a treat in store. All the varieties of the common myrtle are slightly nipped, but this often happens and seems to make little difference to their flowering when August comes round. Myrtus (Eugenia) apiculata and M. Ugni stand frost better, in spite of the fact that the latter species makes its young growth very early in the year; its strawberry-flavoured fruits make such excellent jelly that it is worth growing on that account alone. By the way, can the fruit of the common myrtle be put to any economic use? It is nearly as sour as a sloe, and suggests the possibility of "myrtle gin."

In a particularly snug corner Embothrium coccineum looks rather less miserable than usual; it makes a few feeble shoots annually, but has never flowered here. I am inclined to think that this most gorgeous of flowering trees resents coddling and prefers an open situation, provided, of course, that the district is a mild one. It is also rather difficult to obtain a really healthy young plant to begin with, but everyone who has been in Cornwall when the embothriums are in bloom must admit that it is worth every effort to attain success. The evergreen Eucryphia cordifolia has come through untouched, but a small plant of E. pinnatifolia perished—not from cold, I think, but the natural cussedness of this wayward but lovely shrub. Fortunately, Tricuspidaria lanceolata (Crinodendron Hookeri of former days) is much more easily satisfied and rarely suffers from frost in this district, although it carries its buds all through the winter. As it grows quickly, is easily raised from cuttings and is quite unique in flower, this is one of the very best shrubs for localities where it will thrive in the open, but apparently it will not grow at Kew away from a wall.

Abutilon megapotamicum on a wall (also a small plant in the open) has suffered no injury, but the large-flowered yellow variety has lost most of its big soft leaves, but is not permanently crippled. Callistemons, both scarlet and yellow, have only lost a few of the most forward buds. Metrosideros lucida made young growth late in the autumn, all of which was killed by the first frost, though the older wood is undamaged.

The beauty of Lithospermum rosmarinifolium (best of a lovely genus) has been quite spoilt this winter by the flowers and young shoots being so frequently frosted; the leaves also have acquired a yellow tint as a protest against east winds. The ideal site for this splendid little shrub would be in a dry wall facing due south and well screened from the east.

In the front of a warm border, Damnacanthus indicus—a quaint and spiny shrublet 4ins. tall—has come through the last five or six winters unhurt; although it flowers freely it has only once produced its small scarlet berries.

The Madeiran Clethra arborea is badly browned at the tip of every shoot, but this is not surprising, as it sometimes gets killed to the ground even in Cornwall. My little piece came as a cutting from a famous Cornish garden, where this shrub is a grand sight when in flower in August.

BUDDLEIA AURICULATA MAKES RAMPANT GROWTH IN WEST SOMERSET.

Cyclamen persicum, the true species from Tunis and a few seedlings of a cultivated strain, were planted out in sheltered corners last summer as an experiment; all have survived and some are just about to flower. Cinerarias (large-flowered and stellata varieties) generally come through our winters outdoors and sow themselves abundantly among shrubs, but the frosts of last November destroyed most of them, and only a few in the shelter of evergreens have survived. That noble foliage shrub, Senecio Petasites, has suffered severely, losing practically all its leaves, which are its principal claim to admission to a choice collection.

Those rhododendrons which are generally known as "greenhouse varieties" do not show any damage, though their flower buds are a good deal later than usual in swelling. R. sesterianum and Lady Alice Fitzwilliam have come through the last three winters unscathed, although two years ago their branches were bowed to the ground by snow on April 1st. R. ciliatum has already flowered well and remains in bloom for four or five weeks. Erica Veitchii has been a mass of flower since early in February and is certainly the grandest of the tree heaths on lime-free soils. The eucalypti look rather weather-beaten, but only one out of my half-dozen species is seriously hurt, *i.e.*, E. calophylla. EE. Beauchampiana, Stuartiana, Globulus, resinifera and coccifera are none the worse and are already making fresh shoots. One side of a plant of New Zealand pink broom (Notospartium Carmichaeliæ) has been browned, but the more protected side is green and healthy.

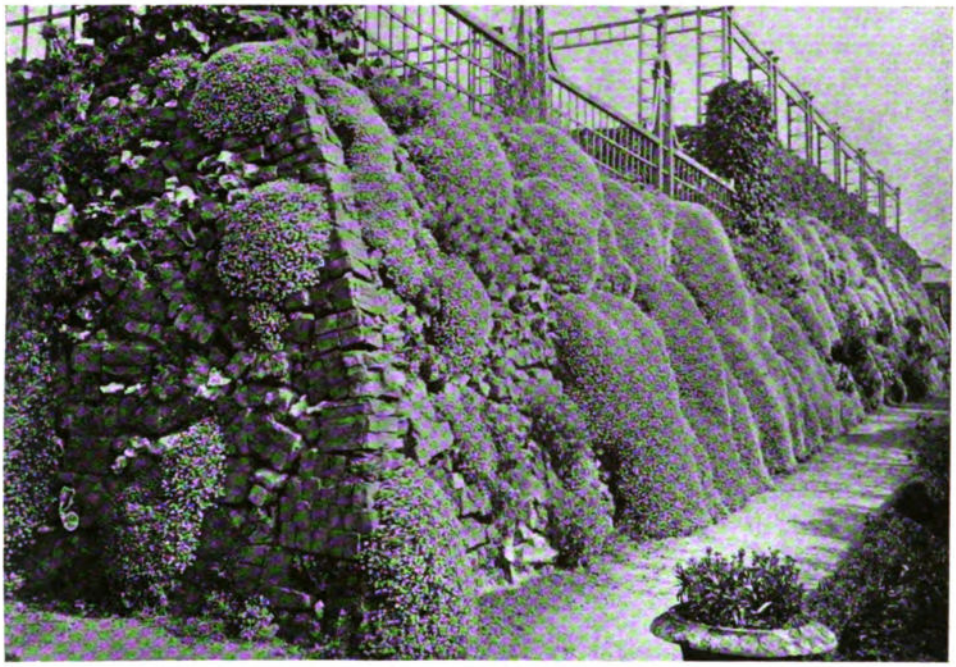
NOTES FROM CONTRIBUTORS



A WONDERFUL PROFUSION OF AUBRIETIAS IN A READER'S GARDEN.

AUBRIETIAS ON A WALL.

I ENCLOSE a photograph taken last Easter Monday of one of our rock-walls here. The aubrietias have been particularly beautiful this year, as the illustration shows.—(Miss) M. HAWKINS, *Kent*.

THE BREAKING OF TULIPS.

THE notion that the breaking of tulips might be caused by the action of some remote disease has not been entirely excluded from the considerations of the Tulip Society, its scientific members regretting their lack of time and opportunity for the necessary investigation, though the apparent vigour and healthy growth of the plants of the broken or rectified tulip rendered the suspicion of disease not very obvious.

In the absence of scientific evidence as the result of well ordered research and judging only by the light of one's experience, the proposition is not one that can be readily assented to, though there are many phenomena that might lend countenance to the idea that tulip bulbs in store in cabinet or on tray may be subjects of infection by visitations of sucking insects. Properly grown, and with due regard to suitability of soil and climate, the progeny of broken tulips can be kept going: vigorous plant, good bloom and sound bulbs following in due succession over a long series of years, though in an experience of thirty or forty years some evidence of "old age" may be noted in several varieties, especially a reluctance to give offsets alongside a bulb of blooming size.

An American friend informs me, "The disease aspect of breaking in tulips has not been definitely investigated."

Professor Griffiths says, "Breaking in other plants is caused by mosaic, and the phenomena are very similar in tobacco and in tulips. The patterns obtained, while not so spectacular in the ornamental tobacco, are quite similar indeed."

Another American scientist has been trying to transmit the tulip mosaic. He says, "Experiments in artificial breaking of tulips have so far not been very extensive and no results have been published. My own results are as yet largely negative. I have pulped up broken bulbs and inoculated healthy bulbs with juices thus obtained without result. I have planted broken and mother bulbs side by side and had a number of them come broken the second year. I have some bulbs which are growing at present which have been inoculated at an early stage of growth which may show results this year."

I understand that at Billingham, Washington, Dr. Griffiths has not had broken tulips among the Darwin and Cottage varieties grown on the experimental acre of the U.S. Department of Agriculture under his direction. "Fortunately," we are told, "the aphids have never been numerous" in their bulb fields.

It is known that aphids transmit mosaic disease from plant to plant in the case of the potato, but scientific results of investigations into the cause of breaking in tulips have not yet been made known either by American or Dutch scientists. In Holland, as in America, some investigation has been made, hitherto with only negative results. Perhaps we may hope for definite knowledge as to the cause of breaking and the cause of mosaic disease in the near future; in the meantime there is nothing to show that breaking in tulips is not a natural result.

It may, perhaps, be deduced that tulips, along with other plants, are subject to attacks of mosaic disease, but it remains to be established that "it is mosaic" that causes the breaking, for tulips may break without having mosaic; research has not yet identified that disease in the bulbs of broken tulips. —CHAS. W. NEEDHAM.

AN ANCIENT APPLE TREE.

I ENCLOSE a photograph of an espalier-trained apple tree growing in West Sussex. The length of the branch from the trunk to the tip is 26ft. The length of the corresponding branch on the right-hand side of the trunk is 22ft., but it used to be longer. It is obvious that the tree used to have a tier of horizontal branches, which have, however, disappeared, except the top one. I know of two other gardens in the district where there are three ancient espalier-trained apple trees, but I have not noticed that apple trees at the present time are trained in this manner. This, however, may be due to my want of observation and want of interest in the subject. The tree is over 100 years old. The girth of the trunk at ground level is 3ft. 9ins., and the girth at 18ins. up the trunk us 3ft. 6ins.; the trunk being much thicker in between these two points of measurement, where the lower branches used to spring out from. —W. M. C.

[Such a large espalier-trained apple tree must be distinctly rare. We should be grateful if our readers could tell us of trees equalling or excelling this one in size. Espalier-trained trees are fairly common.—ED.]

AN ESPALIER TRAINED APPLE TREE WHICH IS SAID TO BE ONE HUNDRED YEARS OLD.

CORRESPONDENCE

PLANTS IN EAST AFRICA.

AS readers of THE GARDEN are invited in the Editor's Post Bag to send any notes on the flowers usually grown in English gardens which are likely to succeed in Uganda, perhaps the following hints may be useful. Those who desire to establish a garden there and grow the old familiar flowers of the homeland should purchase a copy of *South African Gardening and Country Life*, a monthly journal devoted to the interests of horticulture and outdoor life in that great country. It is obtainable in Johannesburg, and in the same city (P.O. Box 1,141) Madeleine's Floral Farms publish an excellent list which includes all the latest novelties in named varieties of antirrhinums, asters, clarkias, Phlox Drummondii, zinnias, sweet peas and a whole host of the annuals so familiar on this side. It must be remembered that the South African seasons are complementary to ours in the Northern Hemisphere, which is at the outset rather confusing; but *South African Gardening* (familiarly known as "S.A.G.") gives a sowing calendar each month for flowers and vegetables, and the time for sowing is given for five different zones. Zone I embraces Rhodesia. Full particulars are given as to how various plants should be grown, the time for sowing, the time when they should germinate, when they should be transplanted (if required) and when the flowering plants should blossom.

The Winton Nurseries, Bonnie Vale, C.P., publish a capital catalogue and deliver plants free throughout the Union, and they will give the fullest information needful to those who reside in any particular district. A new settler will probably be surprised at the up-to-dateness of the nurseries, and will find that the newest varieties of roses, lilies, perpetual-flowering carnations, irises, chrysanthemums, dahlias, delphiniums and many other favourites can be as readily obtained as in the Old Country.

In the Editor's Post Bag (page 274) we read that there are thousands of plants in Korea which have never been grown in our gardens and the same remark is true of South Africa. The present writer has recently received seed of gladioli from the banks of the Zambesi, and has sent out in exchange some seed of the various meconopsis.

It will be curious if an enquiry from Nairobi addressed to THE GARDEN in England should be the means of directing the writer to the source of information to be found in *South African Gardening*, the editor of which journal is a Fellow of our Royal Horticultural Society.

I have two brothers and two sisters in various parts of the colony and frequently send them seeds, and I have sent out a good many plants, including the newest roses from Messrs. Cant, irises from Messrs. Wallace, perpetual carnations from Mr. Engelmann, and chrysanthemums from Messrs. Keith Luxford. The roses and Engelmann's carnations did particularly well, sent out in cold storage. In a very hot district like Nairobi I should try half-hardy annuals and things that are raised in heat here. Unfortunately, it occasionally happens that monkeys have a game with the cucumbers and lions kill a buck in a rose-bed. There are also very bad storms of wind and hail and floods to contend with. Gardening is a quieter occupation on this side!

Roses may certainly be grown there, for an account recently appeared in the Press of how a favourite setter was killed by one blow from a leopard "in a rose garden." The same writer (late of the East African Surveys) states that a few days ago the East African mail brought details of a night visit paid by two hungry lions to a plot behind the house which he recently occupied. They slaughtered and partly devoured a couple of draught oxen alongside a tennis court. On another occasion there came the sound of a wild stampede just before dawn, and a large buck was found lying with a broken neck in the centre of the lawn. Two more were discovered tangled in the fencing wire, and the spoor of a pursuing lion was traced across the flower beds.

Such visits must be very trying to the gardener and, however anxious he may be to make his garden resemble an English one, he may at any time receive some such unpleasant reminder that the conditions are widely different, in spite of the lawn, with its beds filled with English flowers and its rose garden. In East Herts we receive an occasional visit from a fox, and on one occasion a hunted stag took refuge in a conservatory that belonged to a relative of mine, and there she kept it till all hounds had left her garden and horses no longer trampled over her usually well kept lawn. Fortunately, we do not include lions among our garden pests in this country—H. H. WARNER, *Hoddesdon*.

NOTES FROM FRANCE.

I AM Scottish, but live in France. In the centre of France, south-east of Paris, where the climate is hard till the spring sun shines and where corn, beet and roses grow richly in the heavy sandy clay loam. "Terre battante," as it is known here. My home is the ancient Cochet Nursery Garden. Cochet was the father of rose growers. Maman Cochet first saw light here. *Le Journal des Roses* was edited in this house throughout a century or more. I came to it in 1920 and found it in tangle and disarray, neglected before and during the war. The grounds were full of barley and haricot beans. To-day it is April 25th, 1924. The winter has been harsh and bitter. Raging winds have swept this plateau, in spite of its ring of grey walls. Yet, ten days ago a quick, all-embracing warmth succeeded the horror and is still with us. The whole property is snow-clad with fruit blossom: pears, plums, apples—only the peach is over, scattering pink petals. In front of the house is a blazing clump of rose-red. It is a seedling of Rhododendron Aucklandii, coming enthusiastically into being in spite of adverse prophecies and almost as beautiful in another way is a small caucasicum, Cunningham's Sulphur with yellow blossoms. I brought these plants in 1922, much to their delight, from England. Spiræa Van Houttei, Prunus triloba and Viburnum Carlesii are all in full fettle, close together, and illumining imagination for future group-schemes. The gooseberry bushes are hidden by a drift of Rhododendron Loder's White late in blossom for the season. But above all description is the beauty of the poplar wood. This had evidently been a neglected collection of trees intended for sale and planted far too close together. Through it I cut glades, and after fierce battles with the slugs and snails in possession I achieved a vista of loveliness this day through aisles of grey trunks breaking into green that nothing can surpass. Gigantic daffodils, despised in Vincent Square but Emperors of this fine situation, vie with the palest parchment cream narcissi with orange crinkled lips. This forest of tinted yellows, waves above purple-shaded St. Brigid anemones and nods across a few inches of grass to Munstead polyanthuses, white and yellow tulips, ahd forget-me-nots, the whole lot unexpectedly hedge-high. But beyond these what was meant to happen has happened—how rare a thing in life or gardens—a glorious assemblage of reds. Gesneriana tulips and Keizerscroon, Blood Red wallflowers, and Anemone fulgens growing impertinently beyond all repression, and here and there accidentals of white forget-me-nots and Muscari Heavenly Blue that I had forgotten all about these two years. This *parterre* mingling with the yellow and purple and dipping into distant shadows of light green, the gay *cinquecento* recalled to life by a jazz tune—the world yesterday and the world to-day—and being so entirely beautiful and satisfying all in the same moment, a simple combination in an original setting, just when everyone had said, "You won't get all this to grow at once in France," caused me to write and tell you about it.—MILLICENT HAWES (Millicent Duchess of Sutherland).

NOTES FROM BRITTANY.

ENCOURAGED by the Editor I venture to send a few notes on my garden on the north coast of Brittany. Although only a few hundred yards from the sea it is somewhat sheltered by high stone walls and where they can have shelter all flowers do well in this poor-looking grey soil, that seems to be mainly composed of chips of granite.

Just now the best effect is made by immense drifts of Virginian stock, self sown in autumn, in all its delightful chintzy shades of lilac and pink. These form a most harmonious setting for large groups of the St. Bavo anemones, to my mind the best of the family for garden effect. They have slightly pointed petals and come in all lovely shades of salmon, mauve, scarlet, crimson and violet; they grow and sow themselves like weeds and flower very early, but for a considerable time as there seems to be an endless succession of flower buds. The leaves, too, are exceedingly pretty. Once planted you will not find it easy to get rid of them.—F. BLOIS, *St. Briac*.

THE SPURGE LAUREL.

WHILE I have always believed the flowers of that dismal shrub, Daphne Laureola, to be scentless, it has just occurred to me that it does not do to be too sure about such things. A few days ago, on passing a flowering bush of Daphne pontica, I was surprised to find that not a vestige of perfume was being given off by its yellowy green clusters. It is well known that the blossoms of this very sweet old daphne are more fragrant under certain conditions (which I cannot define) than under others. But I now find that I have had to know and grow the plant for over thirty years before discovering the fact that it sometimes has no scent at all! This may, I trust, afford some interest, if not a little comfort, to some of those who have lately been contributing their experiences under the above heading.—A. T. JOHNSON.

ZONAL PELARGONIUMS.

IF any of your readers grow the old single pelargoniums, such as were sent out by Messrs. Pearson in the seventies and eighties of the last century, I should be glad to hear from them. I refer to such varieties as The Rev. Atkinson, sent out in 1875; Havelock, David Thomson, Lady Sheffield (1876); Mrs. Leavers, Lizzie Brooks (1877); Titania, Sophie Berkins, Burier (1878); Mrs. Strutt, H. H. Crichton, Aphrodite (1879); Miss Hamilton, Eceria, Beatrix, Edith Pearson, Atala, Dr. Orton (1880); Rose, Mrs. Gordon, Constance, Metis (1881); Kate Farmer, Jas. MacIntosh, Bianca (1882). I should much like to procure any of these if they are still in existence.—J. E. HALL, *The Grange, Leamington Spa*.

NOTES FROM THE UNITED STATES

I AM interested in the series of articles by Mr. R. G. Hatton. I have grown many bush and cordon trees in the past and now that I have additional ground on which to work, I am attempting to repeat over here what I used to do in England, by planting several dozen one year whips this spring; apples, pears and plums as well as various other fruits that may respond to dwarf training. Among the plums I have several varieties both native and Japanese which, according to catalogue descriptions are worthy of being planted. During the four years I have resided here, I have never bought a plum even approaching the poor flavoured Victoria as found in the British Isles. The California plums (Sugar Plums) that come East are magnificent in appearance and beautifully packed. They are almost as big as eggs, but the flavour! I have found some in a basket to be so tasteless that I have hurled them in the ash bin. Even the best have been about as well flavoured as a pumpkin.

California Barlett (Williams) pears are first-class and in the season we can get them in New York at two or three cents each, as large and as fine as the French importations I used to pay 2d. for in pre-war days. As for grapes, the wonderful Californians—bunches as big as English hot-house and really good in flavour—can be had for weeks on end at 8 to 15 cents a pound.

Regarding the trees I am planting, some of the apples are on the Paradise or Doucine, others on the free stock. It took me some time to find someone working on Paradise and the one year trees cost me a dollar apiece against 25 cents for those on the free stock. I understand that dwarfing stocks have been dropped because they were often infested with crown gall and that, having to be imported, the cost runs too high to make them a paying proposition. I have the notion, however, that nurserymen prefer not to fuss with dwarf trees and certainly not to train them for the benefit of small gardeners.

The main idea all along has been mass production; the nurserymen have more or less ignored the small garden. Since the war, however, they have woken up to the fact that there are myriads of small gardens, although in most cases they are all bending their efforts on the production of evergreens; to me it seems as if evergreen madness prevailed, for vast numbers of home gardens contain nothing more than a border of conifers around the house and a lawn. Some day the owners will wonder whether it will be advisable to chop the evergreens out or shift their houses, for the tree sellers are not averse to over-planting and often use subjects that are apt to grow too large for their position. Personally, not being an evergreen crank I have not one in my garden, and precious little grass either. I was told my energy for intensively working my ground and filling it with flowers would evaporate, but if I believed it were necessary to confine myself to mowing grass and watching evergreens, with perhaps an odd bed or two of peonies, irises, dahlias and gladioli, which is the limit of many, I certainly would put the whole plot down to chickens.

I note M. Ch. Leray of Paris has a letter on Stevia serrata, but from his remarks and the illustration on page 114, I venture to state that he is referring to S. paniculata. In America the former is an important florist flower, being most valuable for mixing with other flowers. The plants are raised mostly from seed, being lifted before the frost, as one touch of frost is fatal to all Stevias. Standardised Plant Names lists Stevia serrata as Piquevia serrata and P. trinervia. Bailey's Encyclopedia also states that Stevia serrata as grown by florists is Piquevia trinervia. Stevia serrata is quoted by Johnson as flesh-coloured, with saw-edged leaves, while S. paniculata is described as white and panicled, and this accurately describes the form referred to by your Paris correspondent. This is also the form which is sold in America as S. serrata. It certainly is not sufficiently serrated to be termed saw-leaved. Personally, I am willing to accept the dictum of Johnson as revised by Hemsley and Fraser, and Kew's confirmation of my own impression years ago is an added testimony. So far as true S. serrata is concerned, I am inclined to believe that it does not exist in cultivation in America or anywhere else.—T. A. WESTON, *New Jersey*.

[Owing to the lack of the actual material we are unable to express an opinion of our correspondent's statements.—ED.]

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Daffodils Unsatisfactory (M. H. A., Tiverton).—The daffodil bulbs are sound, but very small and starved. Keep the leaves green as long as possible and replant in good (but not freshly manured) soil. Two years, perhaps longer, must elapse before good flowers can be expected.

TREES AND SHRUBS.

Pruning Jasminum officinale (A. B., Finchley).—There is no definite rule with regard to the pruning of this climber. It is frequently done when clearing up the garden in late autumn, thinning the tangle of growths by removing some of the older pieces and loosely tying in the long trails. Should the plant be in an exposed position, cutting out is usually deferred until March, the mass of growths giving some protection to the older stems if the young shoots are damaged.

Corchorus japonicus (A. B.).—A more generally favoured name for this beautiful shrub is the Double Jew's Mallow, Kerria japonica flore pleno. Cut away all the old wood which can be spared, to encourage new growth. The flowers are borne on the young wood of the previous year.

FRUIT GARDEN.

Apple Wood for Inspection (B. I. D.).—The apple trees are badly attacked by the woolly aphis, and probably by the canker fungus as well. It is too late now to spray them with caustic wash, but that is the best winter treatment. From now onwards they ought to be painted with methylated spirit or linseed oil wherever the white woolly matter that protects the aphis makes its appearance, working the brush well into the wounds and among the galls the pest makes.

Artificial Pollination of Apples (G. N. E.).—To carry out the cross-pollination of apples with any large area outdoors is very difficult and tedious, as to be sure of doing it pollen must be transferred by means of a brush from one tree to another. Pollination, as a rule, occurs naturally; but effective cross-pollination in apples means taking pollen from the flowers of another variety altogether. The only feasible method would appear to be the removal of branches from one variety to the tree it is destined to pollinate, and the use of a rabbit's tail alternately on the flowers of the branch and of the tree.

MISCELLANEOUS.

Papaw Fruit (W. F. D., Dorset).—The papaw (Carica Papaya) is a common tropical fruit which may be eaten when ripe as a dessert, cooked when young and green as a vegetable, or pickled in the green state. Papain, the dried milk or juice of the fruit, is of value for medicinal purposes, and the leaves have the singular property of rendering tough meat tender if it is wrapped in them. It may be noted that yams are the tubers of various species of Dioscorea, and that the sweet potato, which is also of tropical origin, is the tuber of Ipomœa Batatas.

Superphosphate (F. K. W., Surrey).—The manure is superphosphate, and under that name may be obtained of any dealer in horticultural or agricultural manures. Its full name is superphosphate of lime. If our correspondent's vendor has sent sulphate of lime, a totally different thing, an error has been made.

Aucuba japonica (E. M. G., Boldre).—This Japanese evergreen shrub, represented in gardens by a number of forms bearing either green or variegated leaves, contains the glucoside aucubin and is noted in several works dealing with poisonous plants, although no records have been traced giving specific cases of injury to domestic animals. On the other hand, the leaves of the cherry laurel, Prunus Laurocerasus, which contain a substance yielding prussic acid, have caused the poisoning of numerous cattle and sheep on the Continent, but are, apparently, less harmful in this country.

Names of Plants.—A. T., Kent.—Prunus tomentosa.——H. E. B., Bath.—Acer opulifolium, Italian maple.——W. S. M.—Magnolia Soulangiana.

NEW SPRAYING MACHINES

LESS THAN HALF PRICE.

An Exceptional Opportunity.

No garden, however small, is complete without a Sprayer, in fact a Sprayer is absolutely essential to obtain best results. During the War we supplied a considerable number of our well known Four Oaks Knapsack Sprayers—Rubber Diaphragm type—to the Government, and we have just re-purchased a small quantity back again, **which have never been used.** They are made of copper but painted Service grey colour They have various special additions to the ordinary machines, and the price to-day would be **£5** each. We guarantee them to be in perfect working order as new. We will send one machine carefully packed, carriage paid, on receipt of **50/-**, but cash **must** accompany **all** orders. We would supply **2** machines for **90/-**, carriage paid.

Please mention this paper when ordering.

The RITO Smile.

RITO

for the Greenhouse and Garden

Aughsey Arms, Bridetown, Cannock.

"What about **RITO?** The query to those who have used it answers itself. What have been the results? Well, **I used it for Sweet Peas, Carnations, and for general Floral culture with amazing results.** In the vegetables, I was even more successful. In Cabbages the results surpassed anything I have used before. **I took first prize at Cannock Show,** a show of no mean order which it has been named as a second Shrewsbury. I would say to all gardeners I have used it and proved it. Do likewise and you will never regret it." (Signed) H. Hemingsley.

Of all Dealers.—**Prices:** 7 *lb.* 1/9, 14 *lb.* 3/3, 28 *lb.* 6/3, 56 *lb.* 12/-, 1 *cwt.* 23/-, *or direct from the manufacturers: The Molassine Co., Ltd. (G. Dept.), Greenwich, S.E.*10.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Early Potatoes.—Any night we may experience a little frost, so it will be advisable to keep an eye upon the early crop of potatoes. Those well advanced may be protected with a few evergreen branches, but for the bulk a little soil drawn over the growths will suffice.

Brussels Sprouts.—If seeds were sown early in the year and the seedlings pricked off, the plants will now be ready for transferring to their final quarters. These plants need good ground and plenty of space fully to develop, so for the strong-growing kinds a distance of 2½ft. between the rows and 2ft. in the lines should be allowed.

FRUITS UNDER GLASS.

Melons.—Early melons will soon approach the ripening stage, and, when the fruits finish swelling, feeding of the roots should cease, the atmosphere be kept on the dry side and more air admitted. So long as the foliage is healthy the roots should be kept more or less moist, as many fruits are spoilt through lack of water during the finishing stages. Later plants will be growing freely, and when the fruits are set the roots should be top-dressed with good fibrous loam. Keep them well supplied with water, syringe the foliage twice each day, and maintain a more or less moist atmosphere. A little air during the middle of the day will be needed. If a succession is desired, seeds may be sown to produce plants to take the place of others that are ripening their fruits.

Melons in Frames.—Melons can be successfully grown in frames or unheated pits, but better results are obtained if a small hot-bed of manure and leaves is employed so as to give the roots a good start. A bushel of loam should be placed in the centre of each light, and one plant on each mound of soil will be ample. Place the frame in a sunny position, and the light should be closed about 3.30 p.m. after sprinkling the interior with tepid water.

THE FLOWER GARDEN.

Wallflowers play an important part in spring bedding, and this year, in spite of the cold east winds, have given a good account of themselves. A bed of the early-flowering varieties, such as Yellow Phœnix, ought certainly to be grown, and during a mild winter they produce quite a number of flowers. Other fine sorts are Fire King, Orange Bedder, Blood Red and Cloth of Gold. Sow the seeds thinly in lines 1ft. apart, and if the soil is dry give the drills a thorough watering before sowing the seeds. When the seedlings are large enough transplant them 1ft. apart, and when established pinch out the centre, no more stopping being required. Choose an open site and keep the soil hoed to prevent the plants being overrun with weeds.

Polyanthuses.—Seedlings raised early in the season should be transplanted as soon as possible, selecting a partially shaded piece of ground. Old plants having passed the flowering stage may have their seed-pods removed, the roots divided into single crowns, and then set out in lines 1ft. apart. They will be found useful in the autumn for planting along woodland walks if not required for the beds. For a few weeks the roots will need water if the weather is dry.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbages and Cauliflowers.—Plants in their early stages are often attacked by slugs, and so one has always to be on the look-out, especially in dull, damp weather. Where slugs are troublesome lime or soot should be dusted around each plant and the applications renewed after heavy rains.

General Work will include the staking of peas as succession rows of plants advance in growth, and the further sowings of beet-roots, carrots, French beans, peas and garden Swede turnips. The lettuce and radish crops, to be sown at intervals as requirements demand, should be grown on top of the raised ground which has been thrown up between the celery trenches. A little thinning should be done among the early carrots, while later thinnings may be used for culinary purposes. Occasional applications of salt should be sprinkled over the asparagus beds during showery weather.

Leeks.—Where sowings were made early in the year, either in boxes or frames, the young plants will be sufficiently advanced now to plant out. Leeks will grow in almost any soil or situation, although, like other vegetables, they respond to good treatment. Well manured and deeply worked soil is therefore necessary to produce a good crop. Fairly deep drills should be drawn out with a triangle hoe at 12ins. apart, and the leeks set about half that distance from each other in the drills. The usual method of planting is to make nice round holes with a dibber from 4ins. to 6ins. deep, the depth varying according to the strength and length of the plants. Drop a plant into each hole, then push in just a little soil from the top of each hole to cover the roots of each leek as the planting proceeds.

THE FLOWER GARDEN.

Anchusa italica Dropmore Var.—All who love to have blue-flowered plants on the herbaceous borders should certainly include the alkanets. Anchusa myosotidiflora should be quite handsome at present with its myriads of blue myosotis-like flowers. The Dropmore variety, however, is really grand when in flower, especially when several plants are grown together. The plants like a rich and deeply worked soil, and young plants which have been wintered in pots in a cold frame or partly covered up with fine ashes out of doors should be set out forthwith. A good stock of plants can easily be raised from seeds or root cuttings.

Hardy Annuals.—Stations marked on herbaceous or shrubbery borders for seed sowing should be raked fine and, before sowing, sufficient surface soil should be collected from each station to cover the seed. Pass this soil through a sieve or ¼in. riddle over the seed as soon as it is sown, then gently firm with the back of the spade. The old and easily remembered rule regarding seed sowing is worth repeating, which is, the smaller the seed the less covering of soil it needs. Clarkia, cornflower, collinsia, godetia, Limnanthes Douglasii, linaria, linum, nemophila, Matthiola bicornis and viscaria are a few well known and easily grown hardy annuals. Linum grandiflorum rubrum is quite effective when grown in small patches between border chrysanthemums, such as Nina Blick or Abercorn Beauty.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Coleus thyrsoideus.—This beautiful blue-flowered plant is indispensable for flowering during the winter. It may be raised either from seed or cuttings. If the former method is adopted the seed should be sown during this month. Cuttings may be inserted about the middle of June, while plants for furnishing the stages may be propagated as late as the beginning of September. Seeds germinate readily in an intermediate house, while cuttings will root in a close case with slight bottom heat. During its growing season this plant is best kept in a warm greenhouse and when growing freely requires liberal feeding, or else it soon loses its bottom leaves. Large specimens for standing in the beds should be potted on into 8in. pots. Plants for the stages should be flowered in 6in. pots, while later rooted plants may be flowered in 48-sized pots. This plant requires careful watering at all times.

Coleus barbatus has pretty pale blue flowers and is a very desirable plant for the autumn. It should be propagated by means of cuttings at this time. During the summer it should be grown in an intermediate temperature and when in flower placed at the warmest end of the greenhouse, as the flowers are apt to damp off. The many varieties of coleus with coloured foliage are still very popular for greenhouse decoration, and well coloured plants in small pots are very useful for indoor decoration. They root so readily in a warm case and grow so quickly that it is easy to keep up a succession of useful plants for this purpose. Large specimens are very useful for the conservatory during late summer and early autumn and for this purpose they should be potted on into 8in. or 10in. pots. To obtain well furnished specimens the shoots should be frequently pinched. The plants may be trained either as bushes or in pyramid form.

Cinerarias are popular plants for greenhouse decoration, and this is, no doubt, due to the fact that many fine strains of intermediate varieties are now obtainable in beautiful shades of blue, as well as rose. These plants have largely taken the place of the so-called florists' varieties with large regular-shaped flowers, which are less useful for decorative purposes. Seed may be sown from now onwards until the beginning of July, as by this means a long succession can be maintained. The seed may be sown in an ordinary greenhouse, and during all stages of their cultivation the subsequent plants require perfectly cool treatment, with moist atmospheric conditions. During the summer they may be grown in cold frames, or better still, in low pits. They may be flowered in 48-sized pots and in this size are very useful for decorative purposes. Larger specimens for conservatory furnishing are best grown on into 6in. or 7in. pots. If little or no leaf soil is used in the potting compost, much hardier and sturdier plants will be produced. When they have well filled their pots with roots they enjoy liberal feeding. In bright weather they will require shading during the hottest part of the day. These plants are very subject to attacks by green fly, which should be prevented by frequent light fumigations. Towards the end of September the plants should be removed to an airy greenhouse where they can be safeguarded from frost.

ON VIEWING A GARDEN

AT this time of year, when the world and his wife are scattered around the country, many gardens are visited and looked at and examined from every point of view. Now, this is not quite such an easy operation as might be imagined. For friends who have the same enthusiasms it is comparatively simple. They make a bee-line for the latest acquisition or some stubborn plant, and examine it and discuss it together for hours. I am reminded of Mark Twain's story of the blue jay which tried to fill up a knot hole in a roof with acorns; he collected his friends and discussed the question for hours on end. This kind of garden discussion is in keeping with the enthusiasm of those who have reached out beyond the stage of beginners. I have an unfortunate friend who obediently followed me in a tour round some of the Cornish gardens. His bitter complaint was that we passed everything in full flower and centred our attention on some stick which had few leaves and no possibility of flowering within the next decade. He dubbed such plants as nudissimums. That is one way of seeing a garden.

At the other extreme are a class who say that they would love to see the garden and then keep their eyes firmly fixed upon the path and discuss racing and clothes and anything else that may enter their heads, provided that it has nothing to do with gardening.

Between the two extremes are the largest class of men and women, who like flowers and pretty effects but are usually shy and nervous about showing their ignorance. They make banal remarks on the plants and ask questions and make guesses at the names until the person showing them round catches their nervousness, which is infectious, and by slow degrees they drop the subject of gardens and wander off along some bypath. This is unfortunate, for in all probability the visitors are just as enthusiastic as the owner or the gardener, but a little tact and skill are wanted in developing the conversation along the right lines. It is little use showing and impressing a visitor with a fine collection of rock plants if the visitor is only interested in trees. The owner should sometimes remember that he can always see the part of the garden which is most interesting to him, while the visitor may only have the opportunity of seeing his particular branch of the hobby on this one occasion.

On the other hand, I have every feeling of sympathy for the owner of the garden. If I visit a strange garden for the first time, I know that I am being carefully examined to see in what direction my gardening enthusiasm lies. Owners of gardens have to be shrewd judges of character, for there is nothing more boring than showing an unwilling visitor round a garden. The best plan is to state boldly and clearly where your tastes lie. In that way an immense amount of trouble is saved and what might have been a dull afternoon may be very pleasantly spent. I know of several large gardens where distinctly different routes are laid out for showing the garden to visitors according to their taste and knowledge. The first class is shown everything, and the showing takes the best part of a day. The nurseries are not included in the itinerary of the second class; the third is only shown full grown plants, and so on. This is a good method.

There is one disease to which even the most enthusiastic are addicted, and that is horticultural indigestion. If a succession of gardens is visited, there comes a time when we are satiated with gardens and looking at beautiful things. Our mind is filled with a whirl of memories of special plants and varieties of complicated names. There is no cure for this complaint except a rest in some place where there are no flowers, but there is a preventive. I have found it a good plan to carry about a notebook with me in which I take copious notes. When I leave, the notebook is closed and I pigeonhole all that I have seen for future reference, but in the next garden I visit I eschew mental comparisons as far as possible. In this way I can open my notebook at some future date and at a glance my memory is refreshed. I am no longer bothered by trying to memorise a bookful of information and names.

Remember that all keen gardeners are enthusiasts at heart, but, although each may have his own particular hobby, gardening is a subject which should be taken as a whole.

NOTES ON PRIMULAS

BY DR. MACWATT.

AS we stand in our gardens in early spring and see the flowers, so aptly called Nature's miracles, unfolding on every hand, our senses are thrilled with exquisite delight, and we gaze with joy on the growing stems, the spreading green leaves, and the opening buds. At this season Nature appears to sing with a voice eloquent of triumph and full of joyful welcome: triumph over the dark and dreary days of winter—vanquished but recent!—and welcome to the gentler rains and warm sunshine of the approaching months! Almost as we watch we may see the development of life. Under the genial influence of their spring environment the little buds add cell to cell and strength to strength, until at last they emerge as the perfect flower, and Nature is again supreme with a perfection of form and colour which our intelligence can only vaguely comprehend and our most skilful art only faintly imitate.

Earliest and most beautiful among the spring flowers are the primulas. All the temperate zone of the earth is their domain. The meadows, woods and hedgerows of our own country, the wild precipices of the Alps, the unexplored recesses of the dark Caucasus, the Himalayas crowned with perpetual snow, the lofty plateaux of Western China, and the slopes of the vast mountain ranges of North America are glorified and gladdened by their presence. There is no more beautiful or interesting tribe in the whole vegetable kingdom. They possess a charm peculiarly their own, a charm which increases the more closely they are studied, which no familiarity can ever diminish. And not only are they the loveliest of plants, but their beauty lies open to the most casual glance, and appeals to all sorts and conditions of men.

While members of the primula family have been cultivated from time immemorial and may, indeed, be reckoned among the oldest of our garden flowers, the last quarter century has greatly multiplied the numbers of species in cultivation. Most of the newer species come from Western China and for these we are indebted to the labours of Wilson, Forrest, Kingdon Ward, Purdom, and other collectors in that distant region. Mention should also be made of the services of Messrs. Bees, Limited, who have done much in the way of introducing new species to public notice. Some of these novelties are rapidly becoming popular, and are to-day among our best known spring flowers; others, either owing to their scarcity, the difficulties attached to their cultivation, or because their attractions are not such as to cause us to fall in love with them at first sight, are as yet comparatively unknown. It is principally, though not solely, to direct attention to some of these less familiar primulas that this article has been written.

The Common Primrose (Primula acaulis) and its neighbours the Cowslip (P. veris) and Oxlip (P. elatior), are known to everyone. It may not however be generally understood that the parent of the coloured primroses of our gardens is the Caucasian form of the common primrose (P. Sibthorpii), an early-flowering lilac variety, while the origin of the polyanthus is probably a hybrid between the primrose and the cowslip.

Many beautiful varieties of double primroses and polyanthuses are now in commerce and the appearance of new, handsome and vigorous varieties may be confidently looked forward to, as anyone who likes to take a little trouble can raise new varieties on Mendelian lines; in the third generation double flowers are produced from single varieties fertilised by pollen from doubles.

P. Juliæ is a Caucasian primula which is almost too well known to need description. It is the parent of numerous natural crosses with the primrose, cowslip and oxlip; several of which I have exhibited at the Chelsea Shows.

P. Palinuri, the so-called Cape cowslip or Italian primrose, has been in cultivation a long time. Its native habitat is chinks in the rocks in the Apennines above Cape Palinuro. Its tall erect flower stem, crowned with drooping golden-yellow flowers which exhale a strong cowslip-perfume, rises from amid vigorous foliage. It is a variety of rapid growth and fairly hardy in this country, but is seen to most advantage, especially in cold districts, when it is given the shelter of a cold house or frame.

Two beautiful hybrids are Linda Pope and Marven. The first named is probably a hybrid between P. marginata and an Alpine auricula. P. marginata is an abundant species on the Cottian and Maritime Alps and manifests in cultivation its preference for an elevated situation, being best grown on raised rockwork where its rhizomes can find their natural position. In colour it ranges from rich violet to white, and is easily grown if it gets a chance as above described. Linda Pope excels in beauty its supposed parent. Its deeply serrated leaves are densely covered with white farina. It is easy of cultivation. P. Marven is a hybrid between P. marginata and P. venusta, which is itself a natural hybrid between P. Auricula and P. carniolica. The latter is easily grown on good soil, and in its general appearance resembles a purple auricula. P. Marven is a garden cross, is dark violet with a white eye, and flowers in April. It may be characterised as a good doer.

PRIMULA SECUNDIFLORA, FROM A PHOTOGRAPH TAKEN BY MR. FORREST IN YUNNAN.

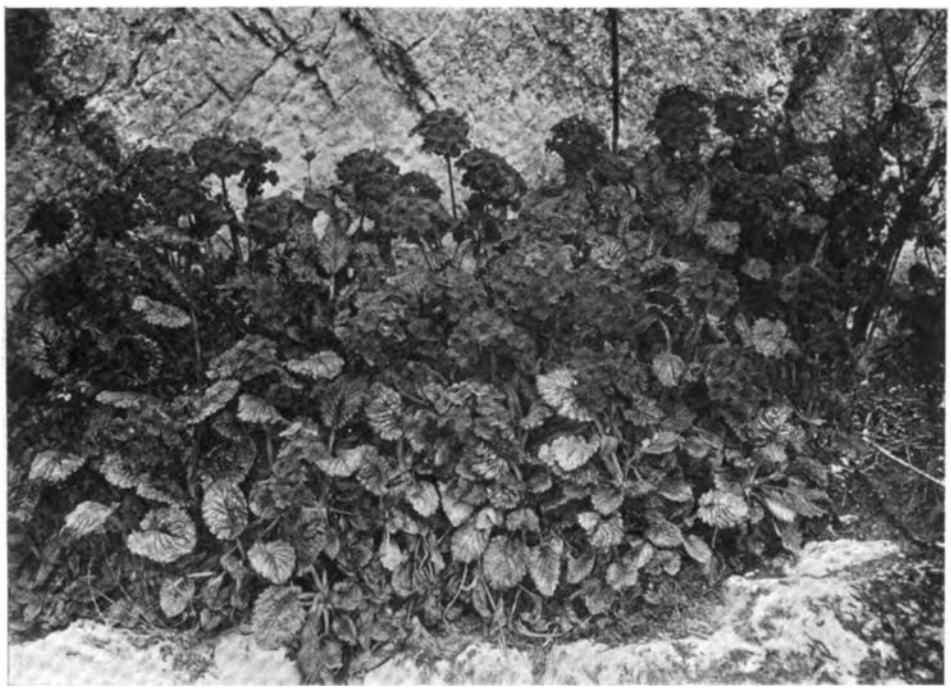
CHINESE PRIMULAS.

Our gardens have been enriched, especially in recent years, by the introduction of a great number of beautiful primulas from Southern China. Among these may be mentioned P. secundiflora, introduced by Messrs. Bees, Limited, in 1908, from seed gathered by Forrest. It carries an umbel of drooping flowers of a deep crimson colour, the outside of the corolla being a little paler, while the calyx is ruddy and banded with white meal. In its native haunts in Northwest Yunnan it grows at a great altitude and it therefore might be expected to be quite hardy, but, unfortunately, it has a decided tendency to rot off at the neck after flowering. As it seeds freely, however, there

Digitized by Google

is no difficulty in renewing one's stock and the same may be said of P. vittata, a plant introduced by Messrs. Veitch, and which in practice it is scarcely possible to distinguish from P. secundiflora.

P. Veitchii is a hardy, free-flowering species which grows well in ordinary soils and bears abundance of magenta flowers in whorls on stems 12ins. to 18ins. long. It much resembles P. lichiangensis, from which it is distinguished by the reddish hairs underneath its leaves. In P. lichiangensis the flowers are larger and more drooping than in P. Veitchii and the anthers are purple instead of yellow. P. Lapala appears to be simply a variety of P. lichiangensis, with the underside of the leaves thickly covered with white hairs. P. obconica is too well known to require description.



ANOTHER OF MR. FORREST'S YUNNAN PHOTOGRAPHS, A FINE CLUMP OF P. RUFA.

P. SINO-LISTERI, A RELATION OF P. OBCONICA WITHOUT IRRITANT LEAVES.

P. Sino-listeri is a plant of great interest, and possesses the advantage of being devoid of those irritant hairs which prove a source of annoyance to many people in P. obconica. It should be hardy in the South of England, but in less favoured districts requires much the same treatment as P. obconica. It forms fine tufts of green orbicular leaves, and carries scapes —usually two-tiered—of white, lilac or pink flowers. P. werringtonensis is the western woodland form of P. obconica. It has rose coloured flowers with a greenish yellow eye. It makes a good plant when grown in shade in a cold frame.

P. heucherifolia, a very fine hardy garden plant, much resembles a Cortusa. It was introduced into cultivation by Miss Willmott under the name of P. Gagnepainii. It has soft crinkled leaves and bears an elegant head of bell-shaped flowers of a pleasing rich purple hue. P. septemloba also resembles a Cortusa. P. geranifolia, a Himalayan form of this last, differs mainly in possessing larger and more open flowers. All the three species are alike in possessing geranium-like leaves. PP. geranifolia and septemloba should be grown in a cold house except in the most favoured districts; P. heucherifolia is hardy in the open.

P. pycnoloba is one of the most singular of the whole family and has been appropriately named "The Hooded Primula." The lobes of the calyx are large and shaggy; from them emerges the trumpet-like corolla, white with the mouth tinged with red. The glossy-green leaves are cordate in outline. Resenting pot culture, it should be planted in open soil, but will require the protection of glass except in the Southern Counties.

P. Forrestii is another very distinct primula. It is of under-shrub habit with stout stems, surmounted by dense tufts of leaves, the closeness of which is increased by the retention of desiccated old leaves. Its flowers are deep yellow and delightfully fragrant. Unfortunately, this very characteristic plant is not quite hardy in the North. P. rufa much resembles it, but appears to be a shade hardier; its distinguishing feature is that it has more rusty-brown hairs on its leaves. If planted outside these primulas should be placed in the crevices of almost perpendicular rockwork with a shady exposure, damp being their chief enemy. P. redolens is a pinky-white form of P. Forrestii and is more robust than the type.

P. Littoniana is one of the best known of Messrs. Bees' introductions, and deserves its popularity, as it is a most striking species. It is like a red hot poker, with scarlet bracts and calyces and lavender-lilac flowers in a dense spike, carried on a scape which may be anything from 6ins. to 24ins. in length. The erect leaves are clothed with downy hairs and the scape is mealy. There are two forms; var. robusta is the larger but inferior in colour to the dwarfer variety. This primula thrives in rich soil, but is rather susceptible to damp.

P. Watsonii has little to recommend it as a garden plant; its blackish-purple flowers being rather unattractive.

(To be continued.)

RARE AND NOTEWORTHY PLANTS

BY E. H. WILSON,
OF THE ARNOLD ARBORETUM.

CORNUS OFFICINALIS.

CORNUS OFFICINALIS is the Oriental relative of the familiar Cornelian cherry (C. Mas). It is a native of central and southern Korea, and is said also to grow wild in the Chinese province of Chekiang. In Japan it has long been cultivated, and its fruits are considered by the people of the Orient to possess valuable medicinal properties. As I saw it wild in Korea, C. officinalis is a tree about 35ft. in height, with a trunk 4ft. in girth, and an erect-spreading, rather irregular crown. It is perfectly hardy in the Arnold Arboretum, where small plants are now, in mid-April, flowering freely. The fruits are bright red, thinner and more oblong than those of the better known C. Mas. In the colder parts of the British Isles and especially the East Coast, this Cornel ought to be generally grown. At present it seems little known and quite rare in western gardens, though named and figured in 1839 by Siebold and Zuccarini in their "Flora Japonica," Vol. I, page 100, t. 50. I have been unable to find out the exact date of its introduction into Europe. However, this seems to have been about 1870, for Lavallée enumerates it as growing in his arboretum at Segrez in 1877.

The barks of trees often afford good and obvious distinguishing characters when those of flower and foliage are lacking or obscure. C. officinalis is a very good case in point. In flower and leaf this and the Cornelian cherry (C. Mas) are well-nigh indistinguishable—at any rate, they are so much alike that only a skilled observer notes the difference. The bracts enclosing the flowers are less concave and more sharply pointed, the pedicels are longer, the sepals a little larger and more acute, the petals narrower and more pointed and less

A FLOWERING BRANCH OF C. OFFICINALIS.

re-curved in C. officinalis; but these differences are all relative and inconstant. When grown side by side the flowers of C. officinalis are seen to be of a brighter yellow and the inflorescence rather more lax. The barks, however, are totally different. That of C. Mas is close in texture, dark grey, blackish in appearance, and is adherent firmly on the branches for many years, becoming rough, scaly and flaking off in small patches and showing a grey undersurface on the trunk and old branches. In C. officinalis the bark is red-brown, splitting and peeling the second or third year into translucent papery shreds, which cling to the branches and, with the light showing through, present a pleasing appearance; on the trunk it is grey, soft and spongy in texture, and, flaking off, exposes a pale brown undersurface.

These two early spring-flowering cornels are characterised by having their small yellow flowers in an umbel subtended by an involucre of four opposite and decussate bracts borne on leafless branches. They belong to a little group composed of four species whose distribution is interesting. The well known Cornelian cherry (C. Mas) is native of Europe; another species (C. sessilis) is a shrub with oblong blue-black fruits and is confined to the regions of North America west of the Rocky Mountains; another (C. chinensis), which is a large tree characterised by its small black fruits, is confined to the mountains of central and western China; the fourth is C. officinalis.

Before the advent of the Japanese and Chinese witch hazels, the Cornelian cherry was greatly appreciated in European gardens as the first of spring-flowering shrubs to open its blossoms. In New England it has been very generally planted and, owing probably to the greater summer heat enjoyed here, it fruits abundantly. In the early spring, when its naked twigs are starred with yellow and in the autumn, when laden with its scarlet fruits, the tree is pleasant to look upon. The American species is not hardy with us, and I fear that of China is not in cultivation, though I sent seeds to the Arnold Arboretum in 1907 and 1908 and again in 1910.

A TREE, TWENTY FIVE FEET IN HEIGHT, OF CORNUS OFFICINALIS IN CENTRAL KOREA.

THE CULTIVATION OF CINERARIAS

THE cineraria is no longer the plant that it used to be, nor are its uses limited merely to the decoration of the stages in the conservatory and occasional use in the house. The introduction of the stellata and cactus-flowered types has made it one of the very best flowers for cutting during the winter, where light, graceful arrangements are the aim. The smaller and narrower petals of these, too, have had a moderating effect upon the colour, so that the blues are less brilliant, the crimsons less vivid, the purples less intense, a great point where used indoors and especially under artificial light. This is not all, however, for a number of other softer shades are also found in these smaller-flowered types, that are delightful from every point of view.

Though we have emphasised their value so greatly as a house flower, this does not mean that they are less effective from the garden point of view. They require more space than the dwarfer and more compact large-flowered type—the height is anything from 2½ft. to 4ft.—but, in large conservatories bold groups of the small-flowered hybrids are extremely pleasing. One has but to visit the Chelsea Show of the R.H.S. to appreciate their capabilities in this direction, but both space and height are essential to their successful display.

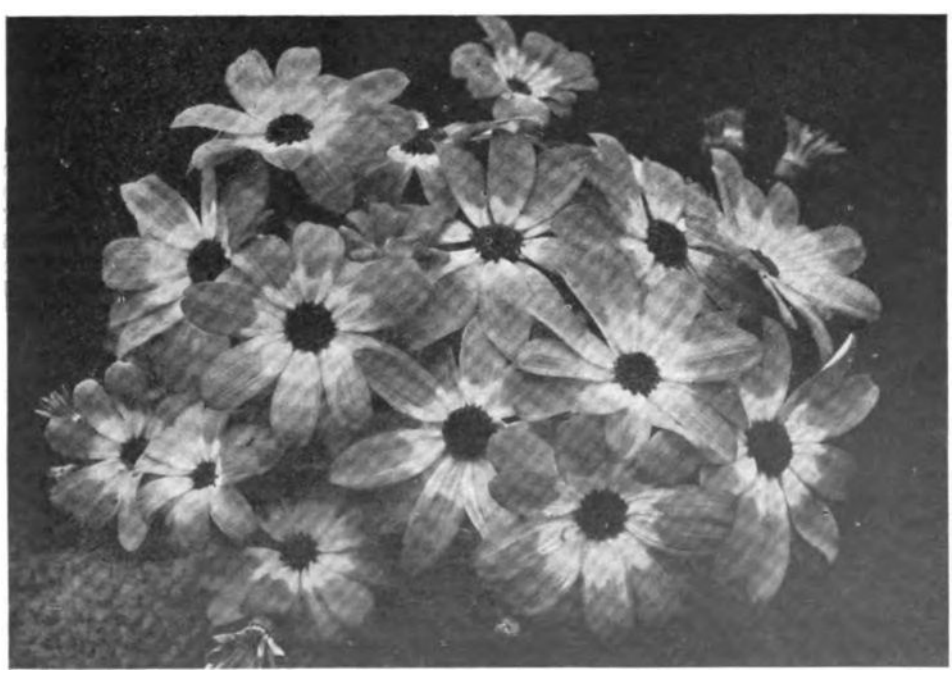
For smaller buildings or where it is desired to produce a solid phalanx of colour of dazzling brilliance, any good strain of English or French origin may be relied upon to give you abundance of material. The English strains are—as a rule—dwarfer, 10ins. to 1ft., while the French attain 15ins., but both will give you a gorgeous display of broad-petalled flowers of large size and gay and brilliant colouring. The blues are often especially sought after and some firms make a speciality of these and offer the seeds in separate packets from the mixed strain. A very striking though not new form is that known as Matador, in which the colour varies from bright scarlet to coppery brown, some examples coming almost a mahogany colour.

Where a long display of flower is desired, more than one sowing of seed will be necessary, but, for general purposes, one is sufficient—made during May. The seed germinates very freely, so that overcrowding should be avoided by sowing really thinly at the outset. Shallow wooden seed boxes do quite well for this and any ordinary light soil will serve, provided only that the surface is made fairly fine. Cover lightly with soil and see that the surface is kept shaded from hot sunshine and evenly moist. The foliage of the small plants is very thin in its texture and readily scorched if—by chance—the soil should become dry and the sun reach them, so care should be taken on this point.

A FINE WHITE FLOWERED CINERARIA.

When three or four leaves have been formed, the young plants are ready for pricking off and this should be done into small pots. Be sure that the pots are perfectly clean and use several pieces of crock at the bottom of each, before the soil is put in. The latter should consist of a good fibrous loam, to which a moderate amount of leaf mould and a good dash of sand have been added. Mix these well together and fill lightly into the pots, then lift and place one seedling in each and press down firmly. The cinerarias make an immense mass of fibrous roots and, to keep the plants dwarf, the soil should be well firmed—otherwise they are very apt to run up too tall.

When pricking off the seedlings from the boxes, examine the reverse side of the foliage for this will give you a useful indication of the most likely colour of the flowers. The reverse side is densely felted with short hairs, sometimes blue, sometimes crimson, sometimes white and so on, this is the hue that those flowers are most likely to be. Selection from these then enables you to obviate a preponderance of any particular colour, a valuable point when mixed seedlings are being handled. Owing to their immense mass of fibrous roots, the little plants establish again very quickly and the sooner they can be transferred to cold frames, the better they will succeed.



MAROON AND WHITE CINERARIAS ARE USEFUL UNDER ARTIFICIAL LIGHT.

Once beyond the seedling stage there are three items upon which to concentrate, in order to ensure success—a cool moist atmosphere, even moisture at the roots and cleanliness from their arch enemy, greenfly. These are not difficult matters, but deviation from them quickly spells the ruin of the plants. In cold frames that face north and have an ash bottom, coolness and moisture are not difficult to provide and the young plants soon make such rapid progress that a shift into pots of a larger size will be necessary. Do not delay this, for they should not be allowed to become pot bound until the flowering size, 6in. or 7in., pot is reached.

The leaf-mining maggot is sometimes very destructive to the appearance of the foliage, but this pest can be entirely eliminated by thoroughly spraying the foliage several times with a

Digitized by Google

nicotine wash which makes the leaves so distasteful to the female that she refrains from depositing her eggs.

For final potting, fibrous yellow loam should predominate in the compost; though a small amount of old manure from beneath a hot-bed is an advantage, with sufficient coarse sand (according to the nature of the loam), to ensure porosity. Retain the plants in the frames as late in the autumn as possible, remembering their love of a cool temperature, but, as the colder days draw on, be careful that too much water is not given or the soil will become sodden. Greenfly must be watched for at all stages, though this seldom proves troublesome while the plants are in the frames, but, at the first signs of its appearance, fumigate lightly and repeat this again if the first has not been effective. When their retention in the frames no longer becomes safe, bring the plants into the coolest house that you have. They do best of all in one where heat is only used to exclude frost, but—in any case—redouble your look-out for greenfly. Nothing is more annoying that to possess a fine lot of plants and then see your labour of months frustrated by these insidious pests. Avoid crowding the plants, sufficient space for the large leaves must be allowed and no single degree of heat beyond that really necessary should ever be employed. Open stages are not good and, wherever possible, the plants should be stood upon either an ash or shingle bed.

Where early flowers are required, the most forward plants should be chosen and introduced into a slightly warmer atmosphere. A very little extra warmth will soon make them grow rapidly and as the centre of the plant (in the stellata and cactus-flowered strains), begins to spindle up, a firm, thin supporting stake should be inserted for its support. Feeding may be done upon generous lines, so far as frequency is concerned, but one must always use this very weak. Water first in the usual way with plain water, then apply just a small quantity of liquid manure really weak and as varied in character as possible. As the spring days lengthen and the sunlight becomes more and more powerful, additional care must be taken to keep the plants cool and lightly shaded when the sun is brightest. Neglect of this considerably shortens the life of the plants, for the leaves and stems will droop and—although they may, to some measure, recover—they never attain their full freshness.

Cinerarias lend themselves especially well to artistic grouping with other plants and those who have a good batch of the various sections can have a most interesting hour, while grouping their plants for display so that the heights and colours present a harmonious whole. In conclusion never forget, please, that their arch enemy is greenfly. This, however, is within the cultivator's control and has no terrors for those who regularly fumigate. H. W. CANNING-WRIGHT.

COMMENTS ON GLADIOLI

IT would be a pretty safe venture to wager that a dozen gladioli bulbs are flowered each year in America to every one in this country. And, *per capita*, Canada and New Zealand, and probably also Australia, have more admirers than we have of this most gorgeous of all the irid family. Why British gardeners have been so slow to welcome the great reawakening to popularity of the gladiolus is not easy to explain, unless, indeed, we accept national conservatism—something of an inborn trait, I fear—as the cause. But evidences are clear and articulate that the renaissance has come, and it is not likely that a flower with such appealing powers will readily fall back into neglect or decay.

I am a true flower lover, of catholic tastes. Before me, as I write, is a vase of sweet and winsome Leedsii narcissi flowers, cool in colour tone and exquisite in form, beautiful enough to take the soul of a Siamese coal-heaver (I put it this way because there are, perhaps, fewer regular readers of THE GARDEN in Siam than in any other country!). I have known the allurements of the May-flowering and the species tulips, the grace and the gaud alike of the lily, the rose and the carnation. I have philandered with the ixia and the auricula, the scandent clematis and the minutest rock plants from the high mountains. But no flower has so enwrapped my fancy, nor granted me so many definite and particular pleasures as the gladiolus. Like most folks, I first embarked on the gladiolus ocean by pottering along the coast line in such little boats as Halley, brenchleyensis and Schwaben; but these have long since ceased to amuse me, for they do not voyage very far, and one wants more modern appliances to set out on the real big-discovery trips to the distant fairylands. In "Inland Voyage" "R. L. S." tells us it is better to journey than to arrive, and there is a deal of truth in that. And so in gladiolus growing it is infinitely better that we should not know whither our experiments lead us than to have accomplished the last possible development of the flower.

There will be great enjoyment for many years to come for all who take delight in cultivating the acknowledged queen of summer-flowering bulbs. The individual flower will take on new forms, also the placement on the spike, while the possibilities of colour blends still to be made are, like the number of the stars, incomprehensible. There are already known some seventy-five distinct species of gladioli, practically all of which, with favourable opportunity, would hybridise together; while the whole genus is composed of some 160 species, some of which in recent years have been assigned to kindred families such as Antholyza, Tritonia, Acidanthera and Watsonia. Now, of this great multitude hardly more than twenty species have been utilised to build up the modern garden gladiolus, so the fancy can easily run riot in anticipation of what is still to be achieved. The great majority of the species come from South Africa, though a few are of European and Asian origin, such as atroviolaceus from Syria, byzantinus and caucasicus from Turkey and Asia Minor respectively, communis from the northern shores of the Mediterranean, and imbricatus from southern Russia. It is very difficult to obtain bulbs of many of the species which promise well for hybridising.

Dr. I. B. Pole Evans, Chief of the Botanical Survey of South Africa, has very kindly sent us bulbs collected from the mountain ranges of the Transvaal, particularly the Drakenburg, and though he has given us many useful hints regarding the particular soil in which they are found growing, etc., we have not yet succeeded in flowering any of these. Dr. Pole Evans came over to see us one afternoon when he was home last September, and I was able to show him a strong plant of G. crassifolius which he had sent in April of last year, and which seemed to be on the point of thrusting up its flower spike. To my great disappointment, however, the foliage began to turn yellow a day or two after, and the plant went to rest. It is now (May 5th) just spearing its way through the soil again, and I am hopeful that it has at length realised that summer is not December, January and February in these latitudes, as it has been accustomed to all its life under the Southern Cross. Last year it did not peep above ground till well into July, so it is certainly mending its ways. I shall take full use of this and of G. Ludwigii calvatus, which also shows a disposition to grow, for crossing with some of the garden varieties, if the opportunity serves. We have already managed to secure crosses between G. tristis, the scented variety, and some of our own seedlings, both large-flowered and primulinus hybrids, and I hope next year will show if any great developments may be expected from such a union. The trouble hitherto with this particular cross has been to get flowers on which to operate when tristis was in bloom, the latter flowering, as it does, in April.

While this work of intercrossing species with species, or species with garden hybrids, is perhaps best left to professional growers, there is also an immense field still open even to amateurs with limited opportunities at their command, by crossing the named sorts which they are growing for flower and producing new hybrids of their own. Amateurs often send us flowers from their gardens, raised from seed supplied by us, and many of these would do great credit to them if shown in a group at Vincent Square. In one parcel received from a customer last year we picked out at least three that would have sold very well if named and described in a catalogue. If we could only get the element of scent into the flowers that we already value for colour and form alone, what a stimulus the cult of the gladiolus would have! J. L. GIBSON.

NOTES FROM GRAVETYE MANOR

THE CHARMING WHITE SNOW GLORY, CHIONODOXA LUCILIÆ ALBA.

IT is not always possible to develop Nature's best pictures inside the garden proper, owing to the limitations of space and freedom of planting; but once we embark upon the ever-inviting woodlands we relieve ourselves of any such disadvantages and plant with a free and lavish hand such flowers as are known to appreciate the leafy surface obtaining in these woody lands.

Near the house is a typical Sussex woodland, over the rides of which have been strewn daffodils and other spring flowers in their thousands, not densely crowded together but planted in loose, spreading, picturesque drifts, with plenty of bare surface which gives the necessary relief and enhances the natural beauty of the surroundings. Surely the bulbs—which, I understand, have been planted for over thirty years—were strewn broadcast and put in where they fell, and the result is certainly gratifying, for these spring woodland scenes are very beautiful.

Although the rides and their margins were the first to be planted in this way, these drifts of colour are by no means confined to them, and in many instances they are to be seen streaming away into the distance and losing themselves among the leafless underwood, or blooming conspicuously over a mound half a mile away with the ground about them a carpet of primroses and rapidly developing bluebells.

In order to enhance the beauty of these woodland pictures and improve the vision of distant effects the lower branches of the picturesque old oaks are removed, and thus, with the ever changing shadows playing upon their lichen-covered trunks a woodland picture of considerable grace and charm is revealed.

CHIONODOXA LUCILIÆ ALBA.

This precious early-flowering plant was found by Mr. George Mann when searching the mountains around Smyrna for species of crocus, and to that great traveller gardeners of to-day are indebted for its introduction to this country. To those unacquainted with this charming White Snow Glory the illustration given here will convey much that is desirable. Its pure white, fragrant flowers are borne profusely on stems a foot in height, several stems appearing from a single bulb. It is here seen forming a broad edging to a bed of roses, and has been left undisturbed for several years.

The soil is on the heavy side, but with a free addition of sand and ashes has proved to be very suitable for the culture of this pretty plant.

I have often counted from ten to fifteen flowers on a single stem, and these, as they age, become suffused with pale blue.

Equally valuable as a cut flower as for garden decoration is this Snow Glory, and there should be a great demand for it as bulbs become more plentiful.

I would strongly commend this plant to lovers of alpine flowers for use among carpets of Viola gracilis in the rock garden.

THE DISTINCT AND INTERESTING HELLEBORUS CORSICUS.

THE CORSICAN HELLEBORE (HELLEBORUS CORSICUS).

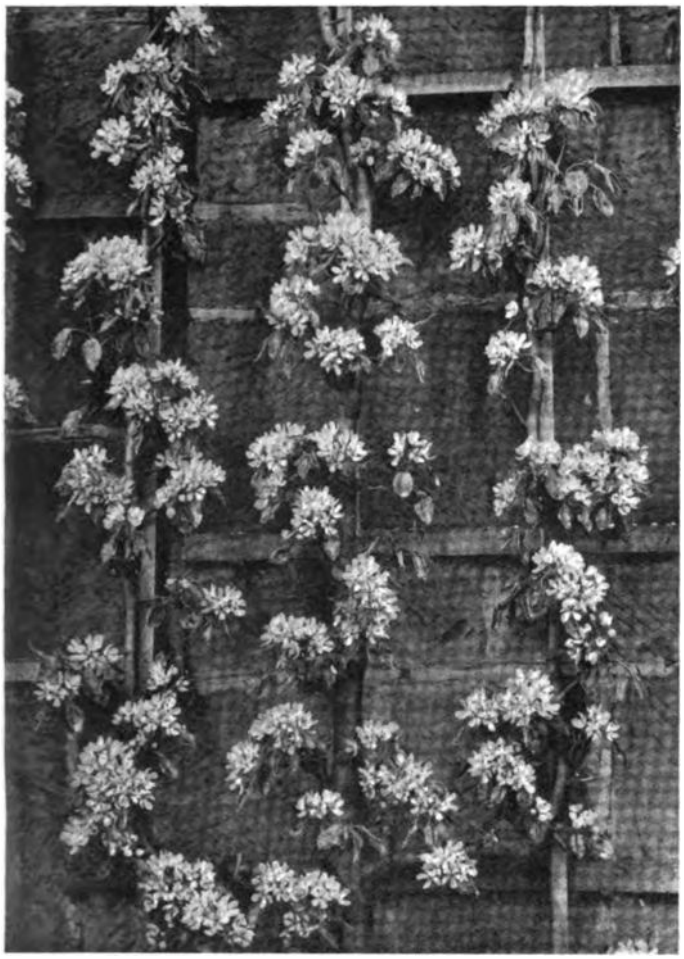
Worthy of attention on the part of gardeners is this distinct and interesting hellebore, which is too rarely met with in present-day gardens. It is not fastidious, either as to soil or position, although a warm and sheltered site which does not become dust-dry at any time and is shaded from the midday sun is much to its liking. Established plants often attain from 2ft. to 3ft. in height and diameter and, even when not in bloom, are features of unusual interest.

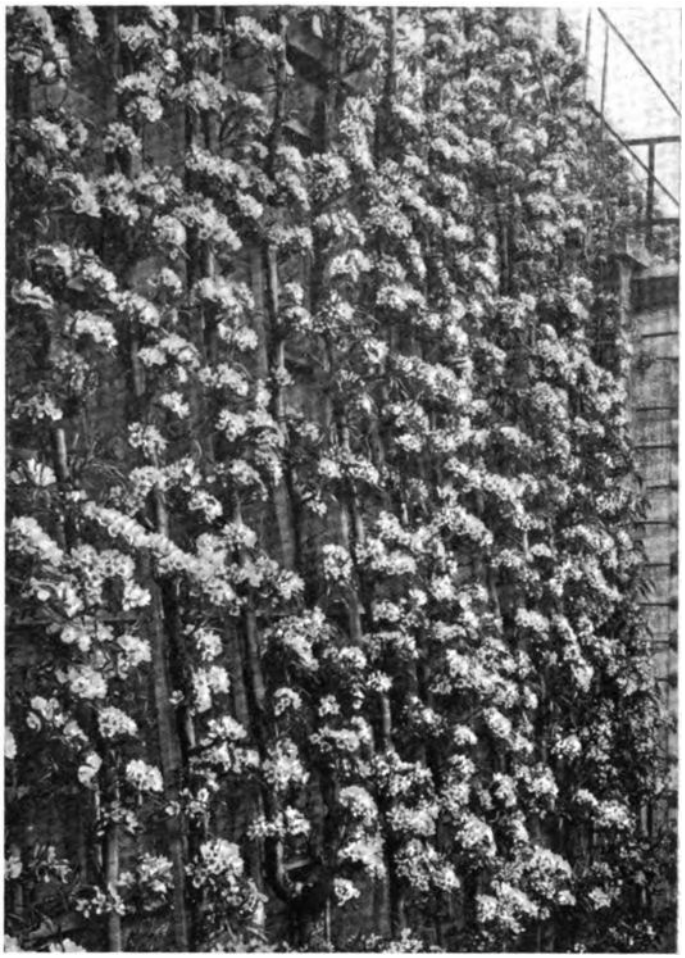
The leaves are large, glossy green above, glaucous beneath, and armed like the holly, remaining upon the plants both winter and summer. Very pretty are the fresh young growths which spring from the base of the plants each year, both the young stems and leaves at that time being tinted with greenish blue. The charming flowers are of a soft pea green, and are borne in large clusters—often a foot in length.

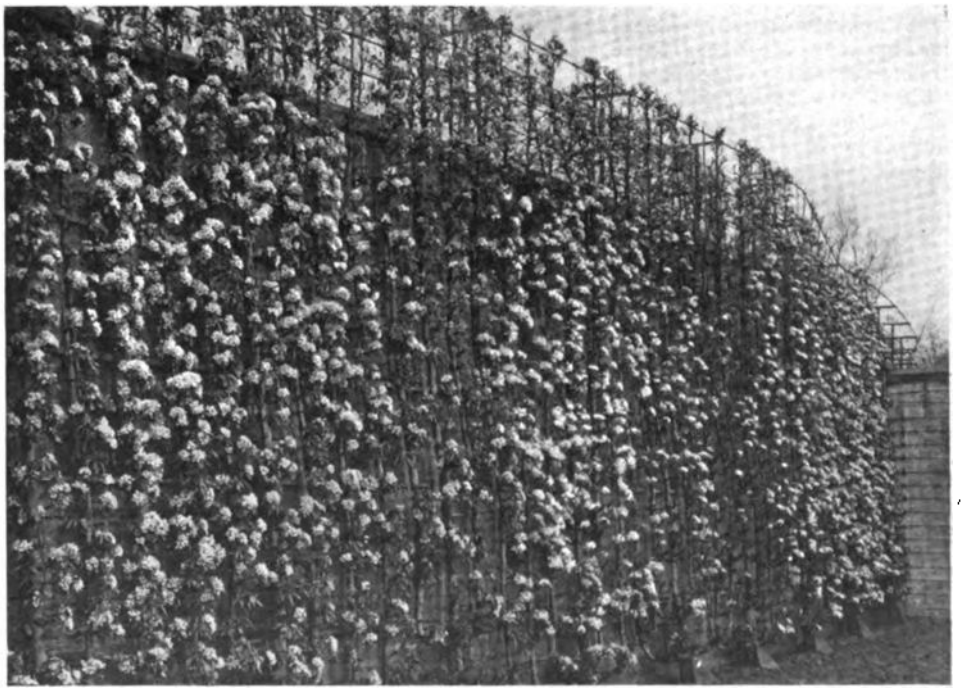
The plant here shown has been growing in its present position—which is a cool and partially shaded slope, facing south—for nine years, and receives little attention.

E. MARKHAM.

Digitized by Google







These three illustrations show better than any words how trained pear trees are grown by Mr. William Robinson. The portion of wall in the photograph is a segment of a large circle, and the pear trees are planted both inside and out. It is interesting to note that there is a variation of five degrees in the temperature between the inside and the outside. The blossom is particularly fine considering the present bad season.

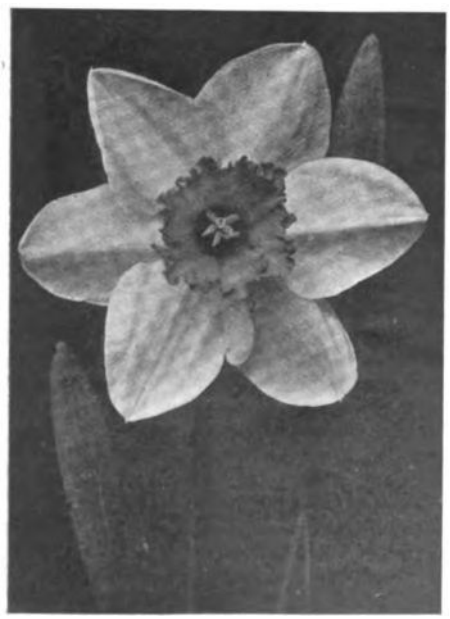
ON SOME FLOWERS SEEN AT BIRMINGHAM

THE large yellow perianthed incomps. Fortune and Helios were both there (see page 322). I had not seen them for a long time, so in a large degree they were both fresh to me. I was very disappointed with Fortune. When I remarked on its coarse appearance I was told, "Oh! it is so early," or "It's a grand flower for market." Well, it is not my taste. That is all. Take away the blinding red from the corona, and what is left?

Were I to be offered a bulb of either Fortune or Helios, it would be Helios every time. As a flower it is quite large enough to please me. Its corona has not the same redness, but it is of a sufficiently deep blood orange to be a foil to the round yellow perianth, while the gentle recurve of its edge is ample to impart a graceful appearance to the whole flower. Somebody told me that Helios was not a good grower, meaning, I expect, that it is a bit particular, like King Alfred. I should very much like to know if it is so. One swallow does not make a summer, or we would not have had the vile afternoons that we had recently—very cold, very stormy and very wet. We call it regular plum, that is, in our local lingo, damson, bloom weather.

In the class for the giant Leedsiis were two very lovely flowers, by name White Sentinel and Mitylene. They were raised by the Brodie of Brodie, whose output of A1 flowers is amazing. I think I was told that they were own brothers, in other words, that they came from the same seed pod. Anyhow, they might have done, there is such a strong family likeness between them. Mitylene has a flat, smooth, flawless perianth, round, white, overlapping, and *just* inclined to be hooded, with a diameter of 4ins. The cup is a very pale lemon, with a diameter of 1½ins. I put it down as one of the flowers of the Show, and with it I couple White Sentinel. This differs from its brother in having the edges of the perianth gracefully and yet symmetrically incurved; and it has rather a longer cup. It would be a puzzle, if I were judging them together, which to place first. It is the question of Almira or Horace over again.



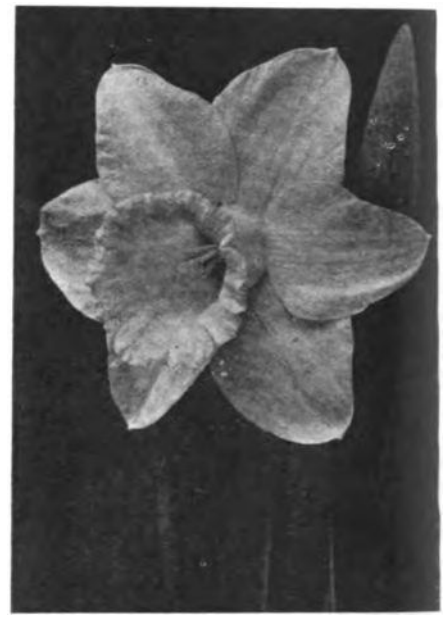
NARCISSUS CASCOB.

I was told the other day of a lady secretary of a daffodil show whose brilliant inspiration will solve the perplexities of all judges. The idea is on a par with the advice that the famous Curé d'Ars gave to the lady who, having had a bad carriage accident, asked him what she could do to avoid another. "Madame," said he, "the way is easy. Never ride in one."

So this lady seeretary had a show, the motto of which was "No prizes, no judges and no jealousy." I will leave White Sentinel and Mitylene there.

Who knows Cascob? Who knows what it is? Cascob is a very taking and vivacious flower which took my fancy immensely, but which will never, perhaps, be famous enough to confer immortality on the small village after which it is named. The flower was raised by Dr. Lower, and, in prosaic language, is an incomparabilis with a white perianth whose diameter is 4⅜ins. The large cup, in shape and colouring, features that of Festive, but both the yellow and orange-red are of intenser shades. Many people say the end of all highly coloured coronas is the market hall. I hope, however, that a thought will be given to their use for *gentle* forcing under glass. They are, many of them, admirably adapted for this purpose. This reminds me, I have two bits of news. A young man from Holland told me that the price of Lady Moore is advancing rapidly. There is quite a little flutter about it, as its splendid forcing qualities are being more and more recognised, and every trader must have some bulbs. He also told me that there are still some Queen of the West in the world. Nothing has given me greater pleasure to hear for a long time. Apart from its own intrinsic loveliness, it calls to mind my old Dutch friend who raised it, and my good English friend who distributed it. The unwelcome eelworm might have devoured many varieties without our being much worse off, but it was another matter when it was Queen of the West. But just think: Queen of the West *redivivus*.

Carmel, of which a picture is given, is a bloom built on strictly "show" lines. If my vote had not been given for Lower's Rewa (see last week's GARDEN) it might have been cast for Brodie's Carmel as the flower of the Show. Somehow, I would never get to love it as I did the charming Queen of the West, but I take off my hat to the "geometrical evenness," both of its pure white perianth and its clear yellow trumpet with its small neat brim. It is all right being a judge if all before you were Carmels, Royalists, White Emperors and White Knights. There is no difficulty then to exercise [illegible] cold neutrality of an impa[illegible] I must mention Fairy Circle; it is so unlike all that I have hitherto written about. It is a very small all-white flower, save for the narrow wire edge of pink round its perfectly flat corona. Several others occur to me as I write—Lavender of Mr. P. D. Williams and Sweet Seventeen of Messrs. Bath. Fairy Circle I think I like better than either. It really is fairy-like. It only measures 2ins. across. These tinies always attract me, but they do not seem quite in their place among the giants to which we are now accustomed. Classes for bantams have been dropped at Birmingham, as they were not very successful. Perhaps one day there will be enough good small fry to make it possible to resuscitate them. Need I say that the old White Knight was often to be seen on the tiers, but in varying degrees of excellence. One bloom measured a good 4ins. in diameter, while not far away there was a second which was only 3¾ins. This is a great difference. I mention it because of a point which was brought up at our Floral Committee meeting. A certain variety was put up for an award by two different people. The blooms of one (X) were distinctly better than those of (Y) the other. As a matter of fact, the variety got an award. The point was, should both X and Y be mentioned in connection with it, or only X, who had the best flowers? The Floral Committee and the Narcissus Committee of the Royal Horticultural Society only judge flowers *as flowers*; their duty is not to judge between the flowers of one grower or exhibitor and those of another. It is a bit of good luck for Y if he is carried on X's back, and I do not see how it can be helped. That these awards are given to the flower and not to the grower is a principle from which committees must not depart unless their functions are legally changed.



NARCISSUS CARMEL.

JOSEPH JACOB.

THE TRURO SHOW

IT has been said that people who live in Cornwall, garden because they have nothing else to do. If this be true, the Truro Spring Flower Show, which was opened on May 6th, is witness to the fact that Cornishmen are, at any rate, not idle.

There are, of course, other flower shows, bigger flower shows, and flower shows of equal interest elsewhere, but there is no other which is quite like that at Truro. Originally started as a bulb show, it has become more a show for flowering shrubs, the date of the annual fixture having been altered to admit of this, and those who would see the rewards of gardening in the far West will be well repaid by a visit to the Spring Flower Show.

This is said to be an exceptionally bad year for rhododendrons and other shrubs, due, perhaps, to the drought of some two years ago, a heavy blooming year in 1923, followed by a winter exacting in its demands upon the plants and protracted in its duration. If, however, this year's show be 25 per cent. below standard, as is stated, the exhibits indicated the wealth of plants that the Cornish gardens must have, rather than the severity of the winter through which they have passed.

Rhododendrons are, of course, a feature of this annual display and the seemingly unending strain of new species still finding its way from China to this country finds expression in the exhibits from the gardens of Mr. J. C. Williams, Mr. E. J. P. Magor and others in Cornwall whose interests so far as the garden is concerned are chiefly centred on the cultivation and hybridisation of this genus.

Among the outstanding features of the show was an exhibit staged by Mr. J. C. Williams, but not entered for competition, consisting of a selection of rhododendrons, both species and hybrids, raised at Caerhays. These included neriiflorum which, for intensity of colour, was outshone by some sprays of hæmatodes, which in size of leaf testified to their exceptional cultivation, the daphne-like ledoides, mollecomum, leptothrium and orbicular—the last-named of which must rank among the best for form as well as for colour.

Another noticeable specimen included in this exhibit was a hybrid between Soulei and campylocarpum, which in its form bears resemblance to the former and in its pale sulphur colour claims relationship to campylocarpum.

Another exhibit, not staged for competition, which calls for special mention, was that sent from Tresco (Isles of Scilly). And what a pity it is that echiums at the end of a long journey in a basket retain so little of that intoxicating glory that they show before being cut. However, with the aid of Miss Dorien Smith's paint brush, those of us who have not seen these plants growing, were given an opportunity to judge of their lordly proportions, as well as the glory of their colour; for two pictures of the echiums in Tresco gardens made a delightful complement to a very exceptional exhibit —exceptional, not only in the rarity and beauty of the exhibits, but in the wide range from which they have been collected. Among them were included: Bomarea acutifolia from Guatemala, Diosma gracilis, Dryandra formosa, three arctotis from South Africa, Hibbertia montana from West Australia, and Beschorneria yuccoides from Mexico.

Of the classes staged for competition and dealing firstly with shrubs other than rhododendrons, which were judged by Lord Headfort and Mr. Armitage Moore, the first prize in Class I for a group of twelve outdoor shrubs or climbers rightly went to the Rev. A. T. Boscawen for an exhibit including Mutisia Clematis, Dracocephalum arboreum, Corokia Cotoneaster, Chorizema Lowii, Telopea oreades, Diosma uniflora and a remarkably fine vase of Erica melanthera.

Class II was won by Mr. R. Barclay Fox (Penjerrick), with Erica australis, Embothrium coccineum and Andromeda formosa. The last named was shown by several competitors and in each case to advantage, so that it stood out as one of the best plants grown in Cornwall.

Other exhibits among the shrubs calling for especial mention were Staphylea holocarpa, shown by Mr. P. D. Williams of Lanarth, which was awarded first prize in Class IX, and which was perhaps the most interesting exhibit in the show. Edwardsia tetraptera, staged by the Rev. A. T. Boscawen; Banksia verticilata (Mrs. Vereker), and so on.

Of rhododendrons probably the most discussed was a hybrid shown by Mr. E. J. P. Magor, under the name of Brachbooth, and, in passing, one is tempted to express the wish that this diligent hybridiser would christen the fruits of his labours on some other principle. This hybrid between brachyanthum and Boothi is of a bright lemon colour, which comes as something new. This exhibitor also staged a truss of Carneum in the class for three vases of highly scented types. This, though not among the most spectacular, is attractive both in shape of flower and leaf.

The big classes for twelve distinct species and twelve distinct hybrids were won by Mr. A. M. Williams (Warrington Park) and Mr. J. C. Williams (Caerhays) respectively; the former showing twelve of the mountain varieties. The Caerhays exhibit, including a wide range of colour in blooms which in size and shape show the skill and care with which the selection of parents has been made.

Mr. R. B. Fox staged a vase of Lindlyana in the sweet-scented class, which calls for special mention, while the class for a spray of any variety was won by Mr. P. D. Williams with a seedling of his own raising under the name of Garnet.

Perhaps one of the features of this year's show was the large number of mountain forms shown in the rhododendron classes. In these Mr. A. M. Williams was a prominent exhibitor, blooms calling for special mention shown by him included sphæranthum, cephalanthum, saluenense, Martinianum (is this a "mountain form"?) and rupicolum.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Growing Water Lilies in a Shallow Tank (D. M. H.).—Unless the water is changed very frequently, or there is a constant inflow and outflow, however small, of fresh water, in a tank 6ft. by 3ft., it would not remain sweet. Nor is there any other means of keeping stagnant water clean and clear. Water lilies, to thrive satisfactorily, require at least 18ins. of water above their roots. The water hawthorn, Aponogeton distachyon, a floating aquatic, would succeed as well as any in such shallow water. Some turfy loam should be laid at the bottom and the roots held in position by placing several bricks conveniently. The planting may be done this month.

The Treatment of Anemones (Mrs. G.).—The anemones requite a good soil that has been well prepared. It should be on the light side, with a richer sub-soil. If our correspondent lifts the corms in due course and uses some well rotted manure mixed with the portion of soil below the top 4ins., and re-plants in October, there may be another brilliant display of blossom, but from old corms there is a risk of partial failure. It is advisable to sow some seeds every year in a sunny position, in deeply dug ground with a fine surface. Rub the seeds in sand in the hand, cover with half an inch of soil, and be careful about watering. The young plants will flower in due course, and the best can be marked for future planting.

TREES AND SHRUBS.

Lonicera nitida Hedge (E. P.).—The value and treatment of this comparatively new introduction from China as a plant for permanent evergreen hedges is more or less experimental. In the early stages of growth the shrub is very promising, but whether it will stand the annual pruning to which we subject the privet, yew, holly and box has yet to be proved. At present the vigorous young growths will be best shortened back with secateurs to keep the plants in a formal shape for the hedge. As Lonicera nitida is a small-leaved evergreen, it should stand clipping twice or three times during the season with shears, as is done with privet. The shape should approximate the growth of a privet hedge, probably a little wider in proportion to the height, as the lonicera is naturally very bushy in growth. An article by Mr. H. Avray Tipping on Lonicera nitida as a hedge plant appeared in THE GARDEN, February 2, page 57.

Cuttings (S. M. L.).—Cupressus macrocarpa can be increased by cuttings during August and September. Dibble the cuttings in a prepared bed of sandy soil with the shelter of a west wall, fence or hedge in patches of a

Digitized by Google

suitable size to cover with a cloche or hand-light. The large-leaved rhododendrons are seldom propagated by cuttings, the best means of increasing these is by layering and grafting. The small-leaved species and varieties can be propagated during the same period and in the same way as recommended for the cupressus.

FRUITS UNDER GLASS.

Vines Unsatisfactory (C. H. B.).—Undoubtedly our correspondent did wrong in using the soot, sulphur and paraffin solution. He should have applied Gishurst Compound as in previous years; it is a good remedy for mealy bug. The tar on the hot-water pipes would help to complete the damage. Paraffin is very penetrating, and some would reach the embryo buds, even if applied to the bark around them. New shoots may grow from the spurs and rods in a few weeks' time, but they will not bear bunches of grapes, and should be retained, stopped and trained for next year's crop.

THE FRUIT GARDEN.

Pear Foliage Attacked (F. L., Warminster).—The pear leaves are attacked by the pear leaf blister mite, but it is not this which is causing the leaves to turn black. Something in the cultivation, and possibly the spraying which our correspondent has given them, is the cause of the trouble. Bordeaux mixture is quite useless against the attacks of the pear leaf blister mite and, indeed, against any other mite. Bordeaux mixture is an excellent fungicide, but is useless against attacks of animals of any description. The only thing at all useful against the pear leaf blister mite is spraying the trees in November, while they are quite dormant with a caustic winter wash. A simple wash made with 1lb. of caustic soda in 10 gallons of water is useful, but the Oregon wash, lime-sulphur-salt-soda, is much better.

MISCELLANEOUS.

Leaf-soil and Its Use (J. R. S.).—Leaf-soil from birch and oak leaves is the best for use in a garden where leaf-soil generally is beneficial. For mixing with potting composts, for greenhouse plants, it is of great value.

How to Destroy Ants (J. W. C., South France).—The best way to deal with the ants is to trace them to their nests and after dusk, when they are at home, pour into the nest—having made a hole for the purpose—a teaspoonful of carbon bisulphide. This is a very inflammable and highly odoriferous substance, which must on no account be brought near a flame.

Locust Beans (Y. R. T.).—The locust or Carob bean, known also as St. John's Bread, is furnished by Ceratonia Siliqua, a tree of 15ft. to 25ft., native of the Mediterranean region. Large quantities of the pods are annually exported from Cyprus for use as a food for stock, being crushed and mixed with coarse fodder or other ingredients for the purpose. In Cyprus a kind of molasses and sugar-candy is also prepared from them, and upon distillation they will yield from 18 to 25 per cent. of spirit.

Ferns for Identification (Angus Coupar).—No. 1, Aspidium angulare var.—There are numerous named varieties of this fern in cultivation, but many are so much alike it is difficult to distinguish one from another. Although hardy in the British Isles, it may be grown successfully in a pot in a cool greenhouse, using a compost consisting of two parts sandy loam to one part of peat or leaf-soil. After repotting in March the plant should be kept in a moderately close atmosphere for a time. We do not know the name "Grimmondii." No. 2, Asplenium bulbiferum.—This is strictly a greenhouse fern, therefore the minimum temperature should not fall below 45° Fahr. during the winter months. A similar compost as recommended for the aspidium will suit its requirements. No. 3.—We are unable to name the other fern from our correspondent's description. Please send a frond.

Various Questions (T. W.).—Tubers of early potatoes planted in March would result in a crop ready for lifting in June and early July. Those of late varieties would not be mature enough to lift before August, September and October, even if planted on the same date as the early ones. Peas are very similar in the matter of maturing; but the seeds of late sorts often decay in the soil if sown when round-seeded early varieties are. The early varieties, too, fill their pods better late in summer. The branches of old fuchsias should be cut back so as to form a well balanced plant; those of younger ones only require to have the ends of shoots cut off. Forty-five degrees will not be too low for dahlia tubers when started. When growing, 50° to 55° Fahr. will be necessary. After the cuttings are taken the old stools may be planted in June. The chrysanthemum does not require a high temperature at any stage of growth.

THE VEGETABLE GARDEN IN MAY

THE second fortnight of last month we considered as the most busy two weeks of the whole year, and, having passed through that period with a greater, or lesser, measure of success, we have now arrived at the month which can certainly be designated the most worrying of the year. This sentiment all growers of vegetables will undoubtedly agree with, from the small cottage garden enthusiast to the professional private growers and the market raisers. Lengthening hours of daylight are bringing with them more sunshine and higher day temperatures, but what of the nights? Some quite sultry, perhaps several following, and then, when our senses have been lulled into false security, suddenly along comes a nasty little snap of late frost, and, where those proper precautions against such happenings have been neglected, who shall measure the damage that has probably occurred? Blackened young potato haulm or scorched young foliage of other things perhaps meets the eye, and what saddened feelings the careless one must experience, and what mental thrashings he administers to himself. The moral of this is, "Be prepared!" for those frosts have always to be reckoned on, even if they do not materialise.

Another point to watch carefully is the possibility of surface dryness of the soil through extra hot sunshine, which would probably cause distress to young crops. Thorough work with the Dutch hoe is what is required at this season, for that will help to conserve the necessary moisture, at the same time keeping the soil in fine tilth and defeating the aims of the various weed plants that are so anxious to prove a nuisance.

Watering, too, will require consideration, for even in this apparently simple task there is a right as well as a wrong way to set about it. Do not leave this to the last thing before nightfall, so that foliage is well wetted, perhaps, when the frost arrives, for it certainly will tend to harmful effect.

ASPARAGUS.—Though possibly all the seedlings are not yet "up," where sown as suggested in the last notes yet some thinning may be desirable. The final aim should be to have a bed of plants about a foot apart each way, so thin in stages until this is attained. Keep free from weeds, and let this same remark apply to the permanent beds.

BEANS, BROAD.—The previous sowings, the results of which will now be apparent, should be tended by hoe and watering-can, (when warm weather rules), and as height is attained, means of support should be provided. For maintaining succession a further sowing is required now.

BEANS, FRENCH.—If pot-sown plants were raised in April, as suggested, plant them in cold frames to grow on to pod-bearing for earlier supplies than will be got from the open. Early in the morning the lights of the frames should be propped up and the plants syringed. This question of ventilation is very important, especially in hot sunny spells. Shut early in the afternoon. Where 4ft. frames are used they can carry lengthwise two rows of the plants.

BEANS, RUNNER.—Nowadays it is considered best to raise scarlet runners in boxes under glass, sowing the seed early in May and putting the resulting plants into the open ground at the end of the month. More even and better results are thus obtained, and the seed can be germinated in a cool house or frame.

BEET.—When the main sowing of globe beet is well through, the thinning of the rows should be commenced, doing this in two or three operations rather than in one drastic thinning later on. Aim to leave the best and strongest plants in position, about 8ins. apart. After thinning operations, hoe well and carefully around the plants.

BROCCOLI.—Any plants raised in March should be planted out into position on a well prepared piece of ground. Seed can be sown in a skeleton frame, where protection from birds can be afforded, to give plants for later yield.

CARROTS.—If sown as suggested in the last notes they can now be thinned as advised above for beet, aiming to leave at the final thinning about 6ins. from plant to plant. The removed plants are generally welcomed by the housekeeper for flavouring, etc. A dressing of soot is an advantage to this crop. Where grown in pits and frames from earlier sowing the same idea should be utilised, and the plants thinned as required for use while still small.

CAULIFLOWERS.—After hoeing well through the beds of those previously

Digitized by Google

planted, water well, and then apply a mulch to keep the ground properly moist, and feed occasionally with liquid manure. Any plants left over should be planted out as they attain sufficient size, and, to maintain the supplies, make a sowing during the first half of the month as noted for broccoli, carefully protecting with netting.

CELERY.—Plant another batch in hot-bed frames as detailed last time, and get the trenches ready for the reception of plants raised from a February sowing. Plant as soon as convenient thereafter, handling the plants carefully with as little root disturbance as possible in order to prevent any check to the growth. Give plenty of water, as celery can hardly have too much of this.

LETTUCE.—Carry on with successional sowings of sufficient size only to meet demands, and thin out as soon as large enough. The thinnings can be replanted yet awhile to yield supplies. Water well and hoe around the young plants. Watch out for slugs in damp weather and protect seed from birds as they are very fond of it.

MARROWS.—Those young plants of March raising, growing in frames as per previous recommendation, should now be fruiting and will want plenty of water. Hand-fertilise the flowers, ventilate freely, pegging down the vine to prevent it interfering with free air circulation, and remove any weak side growths towards the same end.

PEAS.—Here again crops should have commenced on the planted-out vines, and laterals should be taken off and the points stopped when stake-top is reached. To attain continuation of the supplies through August and September, three or four sowings, at intervals, of late varieties should be made. Once again, beware of mice and birds, or—result: no peas in autumn!

SPINACH.—The very useful New Zealand sort, which, though not a true spinach, acts as such a close substitute in very hot dry summers when the other item is unobtainable, can now be planted out in a sunny spot. One hint—afford it plenty to drink. It is a thirsty plant. Continue to sow the true kind in small quantities at intervals.

TURNIPS, too, can be frequently sown, and seedlings thinned to about 6ins. apart. If grass mowings of short length are available, spread this material over the seed, as it prevents the ravages of turnip fly. Growing crops will much benefit by dressings of wood ashes and soot occasionally, and they should be attended to with the Dutch hoe as freely as possible.

E. BECKETT.

SOME NOTES ON GROUPING AND COLOUR

IT often happens that the most delightful effects in grouping are the results of unconscious effort. The latter, it is true, may also lead to painful incongruities. Even so, one cannot be too sure that an entire absence of foresight and design in the disposition of plants is likely to end in effects that are more displeasing than those over which the most patient study has been expended.

The "colour scheme," the "colour sequence" and other departures of the sort on a grand scale may be as near perfection as the creative skill of the gardener can make them, but that does not imply that they are good gardening or universally admired. Billows of aubrietia in every conceivable shade of purple will produce a sea of colour which insists upon being noticed, but the appetite for such rich fare is liable to be cloyed more quickly than it is by the modest results of much more humble ambitions.

Aubrietia is a very beautiful and singularly useful rock garden and wall plant, but I must confess to liking it best in moderation, and especially in combination with other things. Here, for example, is a bit of low retaining wall which has for its *pièce de résistance* a flopping mass of Alyssum saxatile citrinum companioned by the lovely Aubrietia Lavender. There can be nothing much more delicate than that in kindred tones unless it be a quite informal and accidental little group near the margin of a path. This consists of a mat (no more than 2ins. deep) of Aubrietia aurea variegata, its few pale flowers in a cool lavender scarcely rising above the dainty yellow foliage, while close by are some half-dozen rosettes of Sedum spathulifolium purpureum, their fleshy leaves a plum-red, powdered with a blue-white meal and surrounded by chips of blue-grey granite. You may bring into the picture if you like the purple and red and sombre green of Veronica satureioides which carpets the shoulders of a sunken rock on one side and let your eye wander into a frosty drift of Sedum ternatum which sinks away on the other. But with or without these accessories, that little aubrietia and its stable companion, the purple stonecrop, have attracted more attention this season than has been enjoyed by much more showy things.

A GROUPING OF MOSSY SAXIFRAGES, ALPINE PHLOXES, ALYSSUMS AND IBERISES.

Nature bears witness in a hundred fields to the wisdom of combining blues or bluish purples with the paler yellows, and we have ample proof of this outside the rock garden. A pillar of Golden Hop, for example, entwined with Clematis Lady Northcliffe in smoke blue, is as restful to the eye as it is inspiring and refined. On the strength of this I am hoping some day to see the lovely blooms of C. Perle d'Azur garlanding the soft golden yellow of Spiræa opulifolia aurea.

The flowers of Solanum crispum and the subtle loveliness of Irises gracilipes, tectorum and others afford indisputable testimony as to the charm of blue-lavender and yellow in conjunction, and a notebook reminds me of a suggestion picked up somewhere that no more tasteful and effectual foil for flowers in a pale yellow could be desired than a background of Teucrium fruticans. An equally pleasing union of silver and gold you will find in Potentilla fruticosa var. Vilmoriniana, Elæagnus argentea, Ranunculus graminifolius, in several hypericums, alyssums, and many another. In Nature there are few associations of the kind much more delightful than a weathered roof overlaid with a mosaic of gold and silver lichen. In the garden we have a counterpart of this when the silver filigree of Raoulia australis is studded

Digitized by Google

with countless little yellow knobs. Although the spotless ribbons of Magnolia stellata may flutter with denials on branches naked as pea-sticks, one feels that white flowers which are afforded no deep or full-toned green as a setting with which to emphasise their purity and express their beauty of form are always rather hardly dealt with. The blossoms of the hutchinsias, Cardamine trifolia, Erodium chamædryoides, Helianthemum umbellatum, Linaria pallida alba, to name but one or two, would lose half their individuality were it not for the sullen verdure of their foliage. Nor would Helichrysum bellidioides ever have made such a successful appeal to our affections had it not been for that trickery of bronze-purple which rescues the ermine of its pretty flowers from being engulfed in the neutral grey of its foliage.

That singularly gorgeous shrub, Berberis Darwinii, often appears to stand in need of a companion, something that will serve to emphasise the glow of its blossoms, as darkness aids a fire, and this without detracting from its splendour. Its own foliage is sober enough, but this is so often submerged by colour—and the same may be said of the more elegant stenophylla—that it becomes valueless as a contrasting factor. Grey-greens seem rather to mar the beauty of these shrubs and a yellowy-green is certainly not desirable. The heavy verdure of the common holly and Arbutus Unedo, which stand behind a specimen of B. Darwinii, gives perhaps the right note, but some funereal conifer would probably be even better.

Consider the fragrant, orange "lanterns" which illuminate the deep green leafage of B. buxifolia and compare them with the less fortunate blossoms of B. pruinosa, or B. vulgaris, and the high value of a suitable backing at once becomes manifest.

To say that we owe much to green at any season may be to state a commonplace. Even so the fact is one that may too often go unregarded. In itself green must always be one of the most telling and potent features of the garden, but it is never so essential a part as it is when, as May-time verdure, it pulses with the very essence of young life. But we are apt, especially later on, too lightly to ignore its uses; for is it not to the omission of its saving grace that we may to a great extent attribute not only that satiety which sometimes overwhelms one when confronted by vast masses of gorgeous blossom, but the discord which arises from the clashing of inharmonious colours?

It is in the entire absence of the moderating influence of green that hybrid azaleas so often strike one as being too violent in their flaming hues for that subtle harmony of tones which pervades the woodland garden. Yet some of the yellows, especially that fine old species, A. pontica, are admirable since their colour is a component part of green.

A. T. JOHNSON.

NOTES FROM CONTRIBUTORS

CLIANTHUS PUNICEUS IN SOUTH-WEST SCOTLAND.

SOME of us who have tried to retain in the open in Scotland the brilliant parrot's claw, Clianthus puniceus, have had to deplore its loss, even in what are not the least favoured parts of the country, and where it presented at least some chance of success—a chance we hoped might turn in our favour, but which, to our deep regret, passed us by and left us lamenting. But, happily, there are at least a few places where this clianthus is not only a success but a most delightful and satisfactory plant. The best Scottish plants known to me are those at Monreith and Logan, both in Wigtownshire, where there are some lovely gardens which can boast of plants denied to most Scottish gardeners. That at Monreith is a very fine one, reminding me of one I saw many years ago in the garden of the late Mrs. Lawrenson, of "St. Brigid" anemone fame, near Dublin. But the gifted owner of Monreith will not cavil at my remark that the specimen at Logan is an even finer one than his. A good deal of this is probably owing to the circumstance that, favoured as is Sir Herbert Maxwell's garden, that of Mr. Kenneth M'Doual is even more happily situated in the matter of climate and shelter. The plant at Logan is a truly magnificent one, growing against and overtopping a wall. If I am not mistaken, there is a good one at Culzean also. With its great clusters of brilliant scarlet flowers this is a truly magnificent wall plant where it flourishes.—S. ARNOTT.

THE EUPATORIUMS.

EUPATORIUMS macrophyllum, petiolare, grandiflorum, Raffillii, ianthinum and Weinmannianum are all very useful for flowering during the autumn, winter and spring in the conservatory and greenhouse. E. Weinmannianum makes large specimens when grown on from year to year. For this purpose the plants should be pruned hard back early in the year, potting them on if necessary when they have started into growth. During the summer months they should be stood outdoors on a bed of ashes. Young plants propagated from cuttings early in the year make useful plants for furnishing the stages. E. Raffillii may be propagated at this time, and if grown on into 6in. pots will give a fine show early in the year, while young plants raised at this time last year make fine specimens if potted on into 10in. pots. This plant also makes fine large bushes if planted out in a bed in the conservatory. E. macrophyllum should also be grown in the same way as the last named. E. ianthinum is a small and slower-growing plant, and is best in its second year. The three eupatoriums mentioned have large inflorescences of bluish purple flowers, while E. grandiflorum and E. riparium have white flowers. The sweet-scented E. petiolare has white flowers tinted with reddish pink. The latter is a quick-growing plant, and small plants for the stages may be propagated as late as August, while plants propagated at the present time make fine specimens when grown on into 10in. pots. They all grow in an ordinary greenhouse, with the exception of EE. Raffillii, macrophyllum and ianthinum, which are best in an intermediate temperature during their growing season.—C. J.

TULIP ZANY.

IF any tulip can revive the ancient vogue for broken or rectified blooms, in contradistinction to selfs, that tulip is Zany as grown in pots in a cold house. I do not know its history. It may have originated in England and then gone to Holland, or it may have been born and bred there. At all events, it came to me from Holland. For a very long time every bulb was ear-marked to go to America. Then something happened—what, I have no idea—and I was able to buy what I had for a long time wished to possess. Everything, the proverb says, comes to him who waits; and Zany came to me. It is a very beautiful bizarre, with pale bright crimson markings on a pale straw-yellow ground. Sometimes the red predominates, and sometimes the yellow. I like the flower in both states, but especially when the red is not too much in evidence. Then it is superb. It makes a taking pot plant, as it has good stems, and with cool treatment does not grow nearly as high as the Darwins. It is also very beautiful when used as a cut flower.

Although I was first attracted to it by seeing it in beds in the open air at Haarlem, now I know it from growing it myself I can confidently say it is greatly improved when grown under the friendly protection of a glass roof, but without being unduly enlarged by high feeding. Zany is not a gourmand, neither does it like strong drink.—JOSEPH JACOB.

A GOOD PERENNIAL CORNFLOWER.

FEW of the perennial cornflowers are popular plants, yet some of them are undeserving of the neglect they often experience from hardy plantsmen. As a rule, they are wonderfully distinct from other border plants. The taller species, such as Centaurea babylonica, may be cited as useful plants, as well as the varieties of C. montana, although many consider the latter coarse. The one called C. dealbata is quite unlike most of its allies, and is better suited for a position nearer the front of the border than is C. babylonica. It is only about 2ft. high at the most, and in poor, rather dry soil may not be more than a foot in height. It has pleasing divided foliage and neat flowers of rose or rose-purple. It is quoted fairly frequently in nursery catalogues, but is not a plant which is much purchased nowadays. It grows well in ordinary loam, and apparently likes sun. Propagation is effected by division or by seeds.—S. A.

A RARE TRAILING ERIGERON.

THERE is a little trailing erigeron which is a real rarity in gardens, but which has attractions for many, although it has a distinct failing which operates seriously against its greater favour. It is called Erigeron flagellaris. It grows only some 3ins. high, and has numerous small white flowers on trailing stems. The great barrier to its extended growth is that it requires to be kept well in bounds or it will trail over and root among its neighbours—a consummation not to be desired where choice plants are grown. It is a capital little plant for a rough bank or a spot in the rock garden it is desired to cover with a subject of its character which will bloom from June to September. It is far from plentiful in nurseries, but is offered by a few dealers in hardy flowers.—DUMFRIES.

A PLEA FOR RICH COLOUR IN DAFFODILS.

EACH year sees new daffodils being sent out into commerce in increasing variety. During the past two decades there has been evolved a very great number of new types of the flower. Some of the more recent "breaks" are really magnificent. Apart from these, however, an inspection of the many beautiful exhibits put up at a number

Digitized by Google

of the recent Royal Horticultural Society's meetings reveals the fact that there is, in some sections, an increasing quantity of too-much-alike varieties—at least, so far as the ordinary person who is not a specialist is concerned. There is no doubt that there are many subtle differences to be detected—and by the expert probably easily detected—between varieties that, to the uninitiated, are not at once apparent. Such a condition of affairs is, of course, bound to arise sooner or later, as has already arisen in the case of other specialised flowers, such as the sweet pea, the chrysanthemum and the rose.

This close similarity appears to be emphasised particularly in the case of the paler-coloured varieties of daffodils, both selfs and bicolors. Varieties of varying tints of cream have, too, been in preponderance in most of the recent exhibits above referred to. I do not know whether this indicates that more work is being done in the raising of pale-coloured sorts. It would be a pity if work in connection with the raising of richer-coloured varieties were allowed to drop in any way. Is it an indication that something approaching finality has been reached in connection with the raising of new and distinct yellow varieties?

There is no question whatever that, as individual flowers, these pale-coloured varieties of daffodils are indeed very beautiful. I believe, however, that it is not a mere question of personal taste only that makes me think that the pale varieties are not so effective as are those varieties in which some part of the flower at least is of a bright yellow colour. In my experience, for massing purposes and naturalising in grass the yellow sorts are far more useful than the paler sorts.—HOWARD H. CRANE, *Eastcote, Middlesex*.

BELLADONNA LILIES IN TASMANIA.

I AM a regular reader of THE GARDEN, and some little time ago noticed a picture of some belladonna lilies. I thought it might interest you to have the enclosed photograph of belladonnas growing at my home in Launceston, Tasmania. They have no attention whatever, and come up every year and flower profusely. The bulbs from which this particular bed of flowers sprung I brought from Port Sorell, which is on the coast. They were in an old garden which had been neglected for years, and the bulbs had kept on growing on top of one another, so that there were piles standing up quite 2ft. 6ins. above the ground. We just pulled one of these piles to pieces, put them in a sack, brought them home and planted them out, with the above result. The flowers in front, which are really just a little out of focus and hide the belladonnas to a certain extent are blue agapanthuses, and the combination of the two colours is very effective.—A. LAWRENCE GREEN, *Launceston, Tasmania*.

FRITILLARIA IMPERIALIS.

CLUMPS of this early-flowering plant are now, the third week of April, fast approaching their best condition—this date being, with us, rather later than usual, owing, of course, to the backwardness of the season. Because of the unpleasant smell of the bulbs and any broken part of the plant, the opprobrious epithet of "stink lily" has been cast upon the plant, but in spite of this small drawback the Crown Imperial is a most welcome hardy spring flower, making a truly noble show when there is so little else beside bulbs in flower in the shrubbery or border. Concerning its position in the latter place, it may be well to add that this fritillary should be given a backward site, because it blooms early and is ripening off when one wishes to see the oncoming flowers in their best dress, and this would be marred were the dying foliage of our early friend to be too conspicuous.

In the past there has been some difference of opinion about disturbing and replanting this plant; but it is now generally accepted to be in the best interests of success not to meddle too often with groups that are doing satisfactorily, and a period of from five to seven years or more need not be thought too long for such to remain undisturbed—assuming, of course, growth and flower to be healthy and proportionate. The groups here, with one exception, have not been touched for over seven years, and they are good to-day, though not so full of spikes this year as last, I readily grant: this applying likewise to the excepted clump, which was divided and replanted three years ago.

Crown Imperials flourish in most soils, in sun and in shade, but they flower more freely in open soil than in heavy ground and their blooming is a little later and more prolonged in a shady situation than when in full sun. There are yellow and red forms of this species. Anyone thinking their plants really require a removal should attend to such very soon after the foliage has died down.

The fritillaria family is widely distributed, many kinds hailing from Persia, such as the subject of this note, others from parts of Russia, some from North and South America India, Spain, and at least one species is native of Britain, namely, Fritillaria Meleagris, so called on account of its likeness to the guinea-fowl.—C. T., *Ampthill*.

BELLADONNA LILIES, WITH AGAPANTHUSES IN THE FOREGROUND, GROWING IN A READER'S GARDEN IN TASMANIA.

MISTLETOE ON A ROSE TREE.

I BEG to enclose a photograph, the interest of which is greater than its beauty; but I never saw another case, nor have I been able to find anyone else who did. The

A NEW HOST FOR MISTLETOE?

subject is a bunch of mistletoe growing out of the stem of a climbing rambler rose in the middle of our kitchen garden. There is no other mistletoe within a very considerable distance, and certainly none in the kitchen garden, which is a large one, over an acre in extent. The nearest mistletoe I know is a small bunch about 300yds. from the edge of the garden. We have all seen mistletoe on various trees, but never on a rose tree before.—W. O. E. MEADE-KING, *Taunton, Somerset*.

WISTARIA BRACHYBOTRYS.

AMATEURS of the wistaria, or glycine as the French usually call this beautiful climber—they object to the German "wistar"—will, I think, be grateful to be told or reminded that there are other beautiful forms which flower ten days or a fortnight later than the commonly planted W. chinensis, and W. brachybotrys has been so particularly beautiful this season on the Riviera, where it is sadly rare, that I feel it a duty to urge its being reintroduced into England. The colour of the large flowers is so much richer in tone, and its yellow eye at the base of the standard petal so effective that it is positively startling in its beauty as seen this season. I suppose it is known and grown at Kew, but never being in England at its season of flower I have never seen it. At any rate, it should be sought out and given a trial! If it succeeds, I am sure I shall reap some thanks.

It flowers at the same time as the late white forms of Wistaria multijuga and makes a most effective contrast with it. Like W. multijuga, W. brachybotrys thrives on calcareous soil, where W. sinensis is not happy. —E. H. WOODALL.

CORRESPONDENCE

NOTES FROM THE ISLE OF WIGHT.

IN response to your invitation in THE GARDEN of the 19th ult., I send you a few notes on a small garden in the Western Wight which may be of interest to some of your readers. I preface them by saying this is by no means one of the proverbial "favoured" gardens, being 250ft. altitude and one mile inland in the face of the Atlantic gales. I begin with the—at present—much-discussed daffodil King Alfred. Four large bulbs planted autumn, 1922, gave in 1923 about two flowers apiece on the top of a retaining wall facing north-west, sheltered by slightly rising ground to the south-east, soil made up (on the yellow clay) of burnt garden refuse and sand. In the autumn all the bulbs were top-dressed with basic slag, and the flowers are (if possible) finer than last year and more of them. In spite of long-continued frosts and blighting east winds the freesias in the open are not far behind those in a cold greenhouse. This is their second year out of doors, and notwithstanding the severe weather we had for so long they are quite six weeks earlier than last year—an early year for most things, and this a *very* late one! Surely a puzzling problem. They ripened seed last year, so they must be hardy. Lachenalias have stood the winter in the open, too, and are pushing up their flower-stems.—C. M. B.

WHITE CYCLAMENS.

IN your issue of April 26th under the heading "White Cyclamens," an illustration appears of a seedling white cyclamen sent in by Mrs. Wright of Lapworth, Warwickshire, and she brings to notice that phrase that appeared in your issue dated March 22nd, "There is a distinct need for a really good strain of white cyclamen." Surely she does not mean by the photograph sent of a seedling white cyclamen that she has now procured that long-looked-for strain, for, judging by the habit of the plant, it is far short of the true type of cyclamen that is wanted. The true type of cyclamen is a plant with sturdy foliage, with the flowers just appearing above it on good stiff stems, not falling all around the pot on 12in. flowering stems, as it appears in the illustration. Surely if Mrs. Wright had seen the strain of White Wonder cyclamen that Mr. Forsyth staged at the Royal Horticultural Society's Hall she would admit that at last the cyclamen world had got that true giant white strain, with flowers measuring 8ins. across when fully opened on strong, stiff stems just above sturdy foliage. If she was not fortunate enough to see that exhibit, I am sure if she wrote to Mr. Forsyth, Putteridge, Luton, Beds, he would be only too pleased to send her a photograph of his White Wonder strain, when she would see a really true type of white cyclamen. I am a cyclamen lover myself, and grow over 400 plants every year, and have the honour of a gold medal award for my strain, which consists of eight distinct varieties, including a white, which has flowers of the purest white, measuring 7ins. across, on foliage nicely silvered like the silver-leaved varieties, but I am proud to take off my hat to Mr. Forsyth.—G. S. LONDON, *Forfarshire*.

DUTCH CROCUSES.

I AM glad to see that Mr. Jacob puts the variety Maximilian at the head of his list (see page 309). I rather think I told him a year or two ago that it was the finest of all from my point of view. Dorothea is considered by some to be the same variety. Bleu Celeste is another very like it.

Will Mr. Jacob tell me which is the darkest purple—a black purple? Something far deeper than purpurea grandiflora.

I always understood that crocuses should be planted very shallow, yet Mr. Jacob writes about mice finding crocuses planted 4ins. or 5ins. below the surface. I should have thought this was too deep.—CROCUS.

GENTIANA VERNA.

"FORMAKIN," in THE GARDEN of May 3rd (page 309), asks "if there is any garden in the British Isles where the plant does really grow and look happy and contented?" My answer is, Yes, in the Botanic Gardens, Victoria Park, Bath, there is at present a good-sized patch in full flower, which looks perfectly at home and attracts the attention of all flower lovers by the brilliancy of its colouring. It has been in the same place all the winter, unprotected. I have watched it with much interest.

These gardens are very attractive at all times. The Lent hellebores have been very good, also Tulipa Kaufmanniana, Anemone Pulsatilla and many other favourites.—W. DUGGAN.

I WONDER if this photograph would interest your contributor, "Formakin." We raise Gentiana verna regularly from our own seed and use it as a carpeting plant for other alpines.

In about seven days' time (or longer) our patches should be almost at their best,

GENTIANA VERNA IN DR. JENKIN'S GARDEN.

and I should be delighted to welcome "Formakin" if he would care to see them.—N. W. JENKIN, *Hindhead*.

I HAVE just read with great interest "Formakin's" remarks on Gentiana verna (page 309), and would like to point out that if he cares to visit the nursery of Mr. Clarence Elliott, Six Hills, Stevenage, I should be pleased to show him established tufts of Gentiana verna, which I feel sure would prove of interest. The plants in question (about twenty) were shown last year at the Royal Horticultural Society's Hall, when the blooms, some two hundred, were greatly admired. The plants are about five or six years old, and the tufts are now averaging 3ins. across. It may be interesting to know they were grown from cuttings, and that since they were tiny plants they have been grown in limestone chips, leaf-mould and silver sand, with occasional top-dressings.—F. BARKER.

SOLDANELLA ALPINA.

REFERRING to the illustration of soldanella on page 303, is this S. alpina? It looks unlike the lovely illustration of S. alpina in Farrer's "English Rock Garden." The way in which the flower stems all appear to spring from a common centre, and the larger leaves than alpina usually has, make it look more like S. montana as described by Farrer.

This year S. alpina has been a failure here, for nearly all the flower buds that were standing up above the leaves at the end of February, and gave promise of a finer display than usual, were destroyed by the cold spell early in March. It seems curious that a high alpine like this should be damaged by sixteen degrees of frost, but perhaps it was the biting wind that accompanied the frost that did the harm.—R. B. C.

THE PROPAGATION OF CHOISYA TERNATA BY CUTTINGS.

I HAVE had a similar experience to that referred to on page 309, issue May 3rd of THE GARDEN, by Mr. H. Stewart Wacher. I inserted a number of cuttings in a sandy compost in small pots. Some were of young wood with a small heel of old attached; others were of older wood with old wood heel portions. The former rooted in due course, one of the resultant plants forming a bush 7ft. high and 7ft. across about fifteen years afterwards. For the past fifteen years it has been cut back hard, as it outgrew its allotted space. The hard-wood cuttings callused and lived—retained fresh leaves—for several years, but never made satisfactory plants. They absorbed moisture through the callused stump. Hard wood cuttings of roses have struggled for life in this way, but eventually died.—G. G.

I WAS very interested to read the contribution in THE GARDEN, May 3rd, page 309, by Mr. H. Stewart Wacher, under the above heading, as about three years ago I had a similar experience, although, unfortunately, I am unable to state definite dates. I inserted a dozen cuttings of half-ripened wood in a "sand frame" built against a pit facing north, the average temperature of which was about 48° Fahr., and I fully expected the cuttings to root in two months; but over a year passed and still no roots developed, although I had periodically taken the cuttings out and pared the callus. At the end of sixteen months the cuttings looked as fresh as when inserted, retaining every leaf, so I shifted them into a frame containing coconut fibre in a temperature maintained for rooting tropical cuttings, with the result that they rooted within ten days and, after hardening off, formed good plants.

With regard to the question as to how long cuttings will remain green with an ultimate chance of rooting, I should like to add that during a few years' experimental propagating with Mr. L. B. Stewart at Edinburgh I noticed cuttings of Eurya japonica, Umbellularia californica and Buxus balearica retained their leaves in good condition for over three years and have then rooted and formed good plants.

More recently I have seen a cutting of Buxus Wallichiana which still retains its leaves, although it was inserted in July, 1921. Whether it will root is uncertain, as many people consider it difficult to root from cuttings.—F. P. KNIGHT.

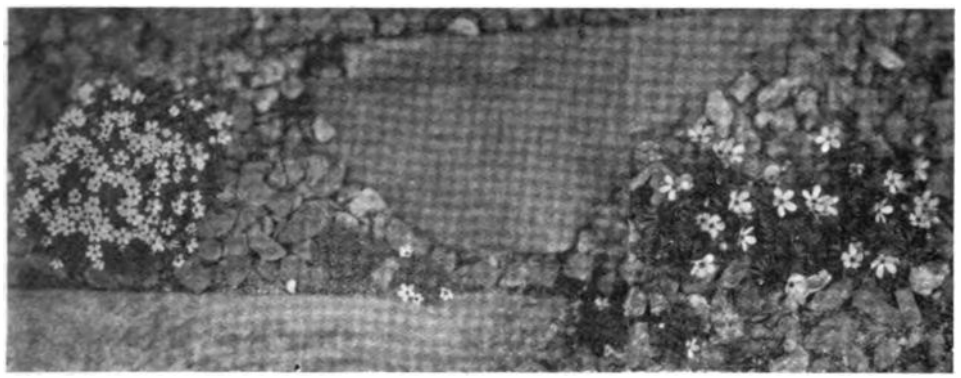
A READER'S ANDROSACES.

I ENCLOSE a photograph I have just taken of Androsace pyrenaica and A. Wulfeniana, both flowering profusely on my granite moraine. The former, you will see, has successfully seeded itself, some of the seedlings also being in flower. The parent plant is just beginning to bloom, but since the photograph was taken the foliage has been almost completely covered with blooms. As these are notoriously difficult plants to flower well under cultivation at low altitudes, I thought the pictures might be of interest to your readers.

The tuft of A. pyrenaica has been established for two and a half years, and forms a dome 1in. high and about 2½ins. in diameter. It is grown in sandy leaf-mould and granite chips in a cemented moraine tank, which is full of water all the summer and drained dry in the winter. A pane of glass is also supported over it in the winter to protect it from the excessive moisture.—H. STEWART WACHER, *Canterbury*.



ANDROSACES PYRENAICA AND WULFENIANA GROWING ON A GRANITE MORAINE.

POTATOES FOR EXHIBITION.

I WAS rather surprised to see some of the sorts of potatoes mentioned by Mr. E. T. Ellis in THE GARDEN, April 19th, page 266, and should have thought he would have met with better and more up-to-date varieties in his experience of judging at various shows. Edzell Blue is certainly too ugly for show purposes and not at all a taking colour. Arran Rose (an early coloured kidney), Witch Hill Early and Midlothian Early all produce excellent shaped tubers and a good size, too, for exhibition. Arran Comrade and Katie Glover for mid-season varieties; Great Scot is too deep in the eyes for exhibition, The Bishop is the most perfect kidney main-crop variety in commerce, faultless in form and comes very even in size, whereas White City often comes all sizes, although with a large quantity to dig from a good dish could be procured. In coloured varieties King Edward VII we know is indispensable, but the new round, Catriona, will be found on most exhibition tables in the future; a good coloured kidney is Mr. Breese, of a pleasing pink colour. Rhoderick Dhu and Arran Comrade I consider the best of all rounds for exhibition. Majestic very often produces a very fine dish for exhibition, but I do not care for the deep set eyes and this is where The Bishop scores over it on the show bench.—W. J. S.

PULMONARIAS.

ALTHOUGH one often sees the Munstead variety of P. angustifolia azurea mentioned in THE GARDEN, yet no one seems to have particularly noted a form or variety which may be either P. saccharata mollis or the true P. angustifolia azurea. The one I am thinking of blooms a little later than its deep blue relative with the plain unspotted leaves and makes quite a wonderful mass of colour and is a far better plant for distance effect in the spring border. Its individual blossoms may not be so pure in colour, and in some years and *some soils* have a considerable admixture of pink; but the general effect, when viewed from several yards away, is usually a fairly good purple.

I cannot think that the Munstead form can have any affinity with it, in so far as the former is usually listed as a variation of P. angustifolia. It is not nearly so effective in a mass, has a much shorter period of bloom, and the flower scapes are (at any rate, in the particular plant I received under that name) somewhat sparse in the number of flowers open at the same time, which are inclined to hang down and therefore do not show themselves so well. The plain unspotted foliage is, in my opinion, most uninteresting, and leaves the impression of a more or less weedy mass for the remainder of the summer.

The other lungwort has beautifully marbled leaves, equalling, if not surpassing, the wonderful veining of some erythroniums. These do not appear in any great force until the flowers are over, when they make an attractive feature of pretty variegated greenery all through the summer and may act as a foil to some autumn blossoms such as Gladiolus primulinus or Schizostylis coccinea.

Even if alone, the unusual elongated shape of the leaves is bound to attract attention. Other good lungworts are the early form of P. saccharata known as "Mrs. Moon," and PP. rubra arvernensis and its white form and styriaca, without forgetting the old P. officinalis or P. saccharata officinalis, which, although comparatively dull, has many uses in the wild garden. I have it as a background to Tulipa Kaufmanniana, and in such company it ceases to be dull and borrows from its neighbour some of the wonderful sunshine that lives in the tulips' orange cups.—EDWARD SHOOSMITH.

THE HARDY SEDUMS.

IN his excellent contribution under the above title (page 260), Dr. Lloyd Praeger omits from his "thirty best" sedums one which I should certainly have included, viz., S. ternatum, and I can only imagine the omission to be one of those slips which are apt to await the ablest authorities. This species is absolutely hardy and its widely-branching cymes of white flowers, born on 4in. to 6in. stems, are very beautiful. With the exception of two or three Mexican species this is always the first of the stonecrops to flower here. That is to say, the blooms open about mid-April and when they go off, some six weeks later, those of S. Nevii, which might be described as a miniature ternatum, break into their frosty radiance. Both of these are American species and both prefer rather cooler soil than one usually allots such things. They spread into a mat of fibrous roots after the manner of the familiar S. spurium, but are far from being aggressive. "Tastes differ," as Dr. Praeger says, but I would certainly include S. ternatum (if not S. Nevii as well) in a shorter list than that alluded to.—A. T. JOHNSON, *N. Wales*.

THE USE OF GARDEN LABELS FOR ALPINES.

I MUST say I entirely agree with the Rev. E. S. Lyttel in his objection to labels in a rock garden (page 308), except in a public institution, where, I suppose, they are still necessary. In fact, I should go further and should not advocate even numbers. A series of little white labels, reminding one of a miniature graveyard, surely cannot improve any landscape, and for me, personally, destroy all pleasure in a garden which primarily aims at imitating Nature. I think most people's ambition when designing such a garden is to arrange the stones so as to avoid all artificiality, and any device liable to destroy this illusion should be omitted. Most true garden lovers do not require any assistance to their memories, but if such is needed may I suggest a rough sketch of the plan be made with numbers written in, with a list of plants to tally at the side, which can be rearranged at will. The old idea that carved pieces of stone from old ruins, woodwork and even broken statuary improved a rockery, as it was then called, has disappeared, and I am afraid I also hope that labels may follow in their wake.—E. B. PALMES, *York*.

"G. G.," in your issue of May 3rd, repudiates numbered labels, and he is, of course, perfectly entitled to his personal opinion. He is even entitled, if he thinks fit, to dismiss as "weak and pointless" any arguments in favour of a system he rejects; but he is not entitled to denounce my system as "laborious," for it is the very opposite.

With written labels it is necessary, when a new plant comes along, either to put in a temporary label and later replace it with a bought or home-made stamped label, or, if wooden or celluloid labels are used, to write one carefully with a special pencil or waterproof ink and also to varnish it if it is to last.

When I get a new plant I simply go to my label box, take an unoccupied number, stick it behind the plant, scribble the name in my book, and the whole thing is done in a minute. Later, at my ease in my study, I ink in the names, adding the date and place of acquisition and, in some cases, the natural order and native habitat, helpful details which would overload a written label.

Above all, "G. G." is not entitled to denounce numbered labels as "eyesores," for that, at least, they are not. If small and buried up to the numbers behind the plants, they are practically invisible, and it is precisely because they are of all labels the least eyesores that, after trying most other kinds, I have adopted these as the best for a rock garden like mine, where a large number of species and varieties are collected into a comparatively small space. For big rock gardens, where the proportion of labels to the number of plants is smaller, the matter is, perhaps, different, and, of course, it is altogether different for public rock gardens where information as to names is sought by large numbers of unaccompanied visitors, who cannot be supplied with number records or be trusted off the paths.—EDWARD S. LYTTEL.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Broad Beans.—Any of the longpod varieties may be sown in good ground with a view to prolonging the supply as far as possible. A cool part of the garden is necessary, and a watch should be kept for black fly. An occasional spraying with quassia extract will hold this pest in check.

Parsley.—A liberal sowing of parsley should be made in lines 1ft. apart, and, directly they are large enough, thin the seedlings to 3ins. or 4ins.

Onions.—This crop should be frequently hoed to keep down weeds, and an occasional dusting of soot will be beneficial. The spring-sown onions will need thinning, but unless large bulbs are required there is no necessity to thin them severely. Medium-sized bulbs are best for general use, and, moreover, they often keep better when placed in store.

Peas.—Further sowings should be made and now it is advisable to sow in prepared trenches, so that the roots can be afforded copious waterings should the weather prove dry. A liberal quantity of well decayed manure should be placed at the bottom of the trench, and the soil be just below the ordinary level. If we experience a dry period, other rows of peas should be mulched, and if manure is not available use grass mowings from the lawn.

Lettuce.—During hot, dry weather it if often difficult to maintain a supply of good lettuces; but at this season there are usually a few empty frames which can be used for this crop. Place the frames near a water tap, and after filling them with good soil to the depth of several inches, prick out the plants 6ins. or 8ins. apart. The lights will not be needed, but plenty of water is essential. Sow a little seed every fortnight.

THE HARDY FRUIT GARDEN.

Strawberries.—When the weather is favourable use the hoe freely to destroy small weeds in readiness for placing straw between the rows. If slugs are numerous, give the soil a sprinkling of lime or soot, and then place the straw in position to keep the fruit off the soil. Nets and supports will be needed in the near future.

Morello Cherries have flowered fairly well, and when the fruit is set growth will make considerable headway, hence it will be necessary to attend to disbudding. This should be done gradually, and it should be borne in mind that these cherries require much the same treatment as peaches. Tie in the shoots when ready, and prevent overcrowding. If green or black fly appears, spray the trees at once with an insecticide, washing the trees with clear water the following morning.

Hardy Vines.—In some gardens these are grown on old buildings or walls, and now it will be advisable to begin disbudding, leaving one strong shoot on each spur. Apart from an occasional crop of fruit, the plant is very ornamental, especially in the autumn.

THE FLOWER GARDEN.

Cuttings and Division.—Many of the spring-flowering plants may be increased during the next few weeks, and preparations made for next season's display. Arabis, aubrietia, the spring-flowering phloxes and iberis can be increased by means of cuttings, which will readily form roots if placed in a cold frame and kept shaded for a few days. Clumps of polyanthuses, especially good varieties, and daisies can be divided; while Alyssum saxatile and myosotis are best raised from seeds.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Brussels Sprouts.—Plants that were set out early should be sufficiently advanced to have the soil drawn up on either side of the stems. This will help to keep the plants in an upright position especially when grown in exposed places. The extra soil around the stems will also tend to encourage the formation of stem roots.

Tomatoes, when in good health, soon become overgrown. Therefore constant attention should be given to pinching out all side growths before they become too large and the tying of the main stems to strings, stakes or wires as the case may be.

THE FLOWER GARDEN.

Bedding Plants.—Antirrhinums should be planted from 8ins. to 12ins. apart in their flowering quarters. Calceolarias should also be planted in beds or borders. When fairly hardy plants of this description are got out early it relieves the pressure of work, when numbers of more tender plants have to be planted later on. All boxes and pots containing ageratum, begonias, centaureas, dahlias, geraniums, heliotrope, lobelia and Salvia patens, etc., should be removed to cold frames. If these plants have been grown under the shade of peach trees or vines, they should be shaded from bright sunshine for a few days, when first placed in the frames, otherwise the tender foliage will get scorched and burned.

Nasturtium Empress of India, which is a dwarf growing variety, may be used as a front line plant on long borders and the seed sown now without fear of having the plants killed by frosts. Shallow holes should be made with a small dibber about 6ins. apart and a seed placed in each hole and covered over. But on no account place nasturtiums on rich loose soil.

General Work.—On herbaceous borders, centaureas, delphiniums, lupins, peonies and pyrethrums should be staked and tied as it is of the utmost importance to have this work done before the plants get out of shape or blown about and broken. Lawns should be frequently mown. Verges should be kept cut with the shears and walks swept and raked. Grass should be cut with the scythe in places where the machine is not used. Roses should be kept trained to arbours and trellises.

THE HARDY FRUIT GARDEN.

Apricots.—The nets used as a protection when the trees were in flower should be taken down now, and where the young fruits are crowded they should be well thinned out. Frequent applications of diluted farmyard liquid manure should be given to the roots of the trees.

Gooseberries.—The berries on bushes bearing large crops should be well thinned at intervals, and the green fruit made use of in the kitchen.

Strawberries.—Plantations coming into flower should have the hoe run between the lines, and all cleaning done forthwith. Then place straw between the lines, taking care to push it well underneath the leaves and close to and around the plant stems, as the object in strawing the plants is to keep the fruits clean. Sometimes lawn mowings are used between the lines, but where straw can be procured it is very much better.

FRUITS UNDER GLASS.

Fruits Colouring.—In the early vinery and the early peach house the fruits should be showing colour. Syringing among the peaches should cease and less damping in the vinery should be done. Air should be freely admitted to these houses when the weather is warm and bright, and although the top ventilators should never be closed down the pipes should be kept warm.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Winter-flowering Begonias, as represented by such fine varieties as Optima, Exquisite, Fascination and Mrs. Heal, should now be propagated as cuttings are available. The cuttings should be secured when they are about 3ins. or 4ins. in length. These are best inserted singly into thumb pots containing light sandy soil. The pots should then be plunged in a warm propagating case, in which the cuttings will root readily. Their subsequent cultivation presents little difficulty if they are grown in a house with an intermediate temperature of about 55°, rising to 60°. Strong-growing varieties, such as Mrs. Heal and Exquisite, will require 6in. pots in which to flower, while the weaker-growing varieties as represented by Elatior and Ideal should be confined to 48-sized pots. These begonias grow quite well in a good medium loam with the addition of a little leaf-soil and enough clean coarse sand to keep the whole open and porous. A little lime should also be added, as it helps to prevent attacks from eelworm. However, where this pest has proved troublesome, it is wise to sterilise the soil by steam or some other means. Begonia mite should also be guarded against by an occasional use of the sulphur vaporiser. The pots should be well drained and water at the root carefully afforded at all times. The earlier propagated plants of Begonia Gloire de Lorraine should be potted on as they require it, while cuttings may still be secured for raising smaller plants, which are so useful for decorative work indoors.

Primula sinensis and its many varieties are general favourites for greenhouse decoration, the stellata varieties being specially graceful and useful for decorative work. Seed should be sown now in pots or pans containing light soil, arranging them thinly on the surface, as they are usually irregular in germination. By sowing thinly the more forward plants may be easily removed without unduly disturbing the more backward ones. Later sowings may, of course, be made according to requirements. During the summer months these plants may be grown in cold frames or, better still, in low pits, where they are under closer observation.

Cestrums elegans, Newellii and aurantiacum are all excellent plants for the conservatory, being seen at their best when they can be planted out and trained up pillars or rafters. In such positions they continue in flower for a long time. They are easily propagated at any time, cuttings rooting readily in a close case. C. Smithii with pink flowers makes a pretty plant when grown in 6in. pots. C. aurantiacum also flowers freely when treated in the same way. Cestrums are all subject to attacks by mealy bug, aphis and white fly, and such attacks should be guarded against.

Ficus macrophylla has smaller leaves than Ficus elastica, and altogether is a much more graceful and useful plant for decorative purposes. Old plants branch freely, thus affording a ready means of propagation, cuttings rooting readily at any time in a close case with slight bottom heat.

Vol. LXXXVIII.—No 2740 Saturday, May 24th, 1924 Price THREEPENCE

The Kelway Colour Border

is planned for continuity of bloom as well as colour effect. Your garden is of enduring beauty from early Spring to late Autumn, and so continues for several years, as a result of the minimum of cultivation, expense and attention.

These Colour Borders have evolved from many years of experience, and clients get the advantage of securing, amongst other subjects, the world-renowned Kelway Specialties in Hardy Plants.

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

We are only too pleased to advise.

WRITE NOW to the inventors of Colour Borders:

A CATALOGUE

I AM much interested by the catalogue of Alpine and Herbaceous Plants, 1924, issued by Clarence Elliott, Limited, Six Hills Nursery, Stevenage, Herts, which has just come to hand. After considerable experience in cataloguing in another trade I can safely say that it is one of the most difficult of all tasks to accomplish successfully. Just put yourself for a moment in the position of a cataloguer. To begin with, you must have a profound knowledge of the subject, you must differentiate and describe items which may only vary in some slight degree, you must be fair in your descriptions and remember your clients as well as the fact that a catalogue is produced to bring grist to your mill; above all, a catalogue must be interesting. This is the most important point, for you must carry the prospective customer's interest right through to the bitter end, otherwise the attention flags and procrastination steps in. "Let us make out our list another day," says the customer, and ten to one he or she forgets, for, after all a catalogue is often a bait sent out to catch regular clients. Once they are safely hooked, they do not wait for catalogues; they write and ask.

Those are a few of the points in a catalogue, and Mr. Clarence Elliott passes these tests of a good cataloguer with flying colours. One of the most successful methods which he uses is that of describing only a few species or varieties of each genus. This simplifies matters for everyone concerned. The issue for the beginner is not fogged by having to wade through countless names of plants, some of which are bound to be very similar, while even the most advanced gardener will find varieties to interest him. Another item of great interest to many gardeners is the number of our rare native plants found in this list. Among them are Cypripedium calceolus, the true Cheddar Pink (Dianthus cæsius), Gentiana Pneumonanthe, Geranium sanguineum lancastriense, Linnæa borealis, Maianthemum convallaria, and so on. Largely owing to Mr. F. J. Hanbury and a few other devoted adherents to our native plants, they are becoming more and more popular in our gardens, and it is pleasant to see them holding their own in Mr. Elliott's catalogue.

The notes and descriptions are short, sharp and to the point. Here are a few taken at random:

Achillea Lewisii. Charming dwarf hybrid, soft sulphur-yellow flower heads, seldom out of flower. Exquisite when grown with Campanula pusilla Miss Willmott. 3 to 4 inches.

Androsace glacialis. We sometimes have live plants of this. (What more could be implied in such few words?)

Arabis albida. Common White Arabis. Pretty but too common to sell. Best begged from a neighbour. (Mr. Elliott might have added that slugs consider the undersurface of a tuft the Ritz of their hotel accommodation.)

Campanula Zoysii. One of the most distinct and fascinating of all the dwarf campanulas, habit of a compact pusilla, flowers of a delicate lavender blue, tube shaped and curiously puckered together at the mouth like a Kalmia. Limestone scree and an occasional sprinkle of Sanitas powder to discourage slugs. Good also for Alpine House.

Phygelius capensis coccinea. We have discarded the old brick-red flowered Phygelius capensis, excellent plant though it was, in favour of this variety, which came to us from a famous Scottish garden. It is certainly an enormous improvement, the flower being brilliant vermilion-scarlet. 2 to 3 feet. On a wall it becomes a climber.

I could continue quoting *ad infinitum*, but I have extracted sufficient to show how the reader's interest is catered for, a secret of a good catalogue. There is one criticism, however, which I can make, and that is that there are not sufficient cultural directions. Every beginner has a rock garden either in being or in process of formation. As a rule a successful rock garden with a percentage of rare plants is not an easy undertaking either to start or to keep up to standard. Such beginners are voracious readers of catalogues and dream night and day of conquests to be made in the plant world. They make up lists innumerable—several of my friends make up a daily one in their bath for their own amusement—but the wise beginner, and most of them are not carried away entirely, weeds out his list until it contains what he supposes are the easiest plants to grow, so as to make a comfortable background on which to form his collection. This information is usually difficult to obtain from a catalogue, and a few lines here and there would be of great assistance. E. H. M. C.

NOTE

MANY who are interested in gardens will be glad to know that Lady Loder is opening the gardens at Leonardslee, Horsham, to the public on Saturday, May 24, Thursday, May 29, and Saturday, May 31, from 12 noon to 7 p.m., admission, 1s. The proceeds will be given to the Sussex hospitals. These are the only days on which the public will be admitted to the grounds, and no doubt many people will be glad to avail themselves of the opportunity of seeing the famous rhododendrons, including Loderi, which will be in full bloom at this time.

Our next issue will contain a fully illustrated report of the Great Spring Show at Chelsea, and will be on sale during the Show.

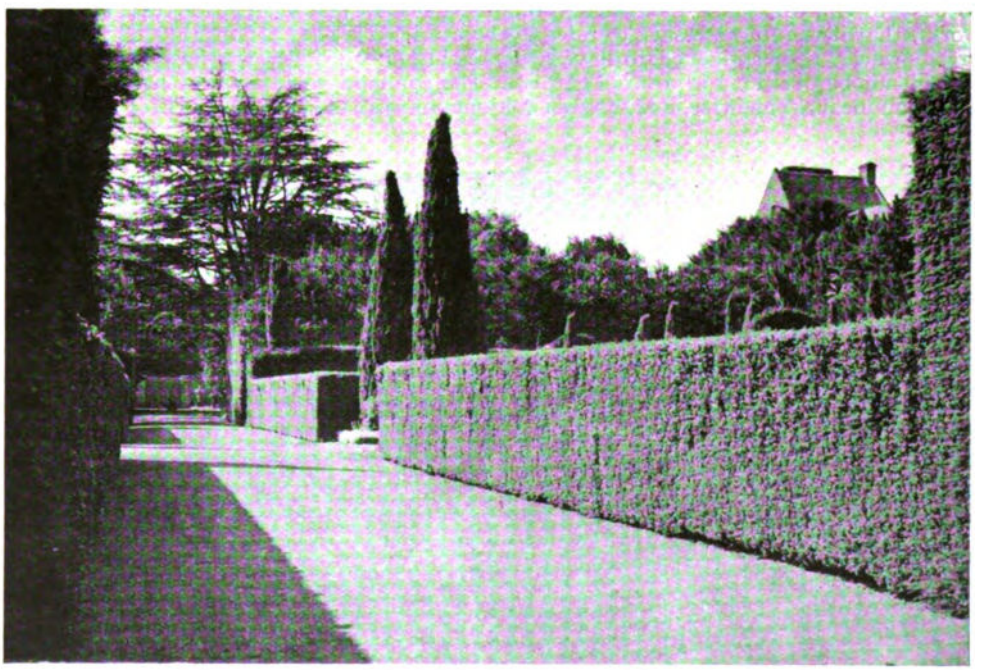
HEDGES

BY EDWIN BECKETT.

IF a visitor from abroad were to ask a native of the British Isles to name one of the most distinctive features of English horticulture, it is probable that the native mind would almost instinctively turn to the hedgerows, with which the countryside is picked out. The hedges which are found in nine out of ten gardens to-day, from the suburban villa to the beautiful grounds surrounding an old mansion, and, unquestionably, the arrangement of hedgerows as boundary lines to our fields, impress the Colonial as quickly as any point he observes wherein this country differs from his own. Often is the expression used, "What tiny fields you folk have, but I must say I like them, especially with their hedges, for we do not see those in our country, only miles of open land, divided off by posts and wires for fences." There is little doubt that a hedge is a native idea, and one that can lend great beauty in unobtrusive fashion to an old world garden, as evidenced by some of the fine old yew and other hedges that may be seen utilised in such fashion. As yet, little knowledge really exists of what plants can be employed for the formation of hedges, and we still have to break away from the old idea that it is essential to form hedges out of that most ordinary plant, the privet. It is true that privets have their use, but a good idea can easily be overdone, and one would feel rather depressed by daily contact with miles of privet hedges; there would really be no excuse for constant repetition, as many other plants can be allotted to the task of serving as hedges. In addition, privet is short lived in comparison with many other plants. These notes will endeavour to attract attention to some of them, but only the surface of the subject can be scratched.

USES OF HEDGES.—Before considering the various items it would be well for a moment or two to examine the purpose of hedges. While primarily they are intended for demarkation of boundaries either between fields or gardens, they are also employed for protection from encroachment, for which purpose impenetrable plants are required, or for shelter from winds and sun for both plant life and animals, or a third idea is to employ a hedge, ornamental in character, to separate one feature of a garden from another, or to screen off an unsightly view. For the first purpose plants armed by Nature for their own protection against cattle, etc., are the ideal, such as the quick or hawthorn, and hollies; for shelter construction, those which make good thick leafage are best, as examples of which we may take beech and hornbeam; while for the third idea, that of decorative effect, there are many fine plants that can be employed, and these will appear farther on in this article. One point should be referred to here. In planting a hedge, it is just as essential that the ground along the position should be carefully prepared and cleaned of weeds, as would be the case in getting ready the site for a good shrubbery, and the planting also should be done as carefully. These factors are most important towards success. After planting, the ground along the hedge should be kept clean and finely broken, the necessary pruning carried out in due season, barriers devised to protect the plants from damage until they are of sufficient size to protect themselves, and, above all, the plants forming a hedge should not be allowed to ramp heavenwards, unrestricted, or it will soon be a case of all top and no bottom, necessitating drastic cutting down in order to close in the bottom again.

A GREAT BEECH HEDGE AT IGHTHAM MOAT.



THE OLDEST OF ENGLISH HEDGEPLANTS, A FINE STRETCH OF YEW.

SUITABLE PLANTS FOR HEDGES.—There are many plants that will make good hedges. Hollies, where they will grow successfully, would, I think, be my first choice: for a well planted, tended, and grown holly hedge is a goodly sight, and satisfactory

Digitized by Google

in appearance at all seasons. It can be used to form low, medium, or tall hedges, making in the last mentioned case a complete and wall-like screen, 10ft. or more in height. To get the best effect, they should be trimmed slightly convex, so that the distance through the top part of the hedge is less than at the base. Being evergreen, careful attention should be given in planting, and I am inclined to prefer late spring for the work, using plants of a suitable height and properly grown by nurserymen for the purpose. Choose plants that are well furnished with growths down to ground level, as a fault with hollies is at times the scanty furnishing low down; also, the plants should have been frequently transplanted. Trim the hedge by clipping, for preference in July, as this tends to aid the proper growth.

Laurel can be used, but generally spreads too much, and becomes untidy, besides having a very scratchy appearance if trimmed with shears, owing to the large leaves being cut across, and not entirely removed. It is a plant that starves its surrounding soil and is not generally to be recommended, especially as it is most undependable as to its length of life.

Privet, spoken of rather disparagingly earlier in the article, does prove useful, and either the common (Ligustrum vulgare) or the oval-leaved (L. ovalifolium) forms may be used, the first for preference; alternated with six times the number of quick, it makes a fast-growing and charming hedge. For low hedges the Chinese Ligustrum Prattii is most useful, and there are a number of other interesting introductions of the genus from the same country that will yet prove their worth for the same work, notably such as the very tiny-leaved, fascinating-looking L. ionandrum, L. Quihoui (which carries enormous panicles of flower, sometimes 15ins. long), and L. Delavayanum, to mention a few of them. Golden privet, too, is frequently employed, but the use of this is preferable in conjunction with the ordinary green forms, provided they are both properly controlled, so as not to mingle with each other, to the detriment of the appearance of the whole hedge.

Quick has been referred to, and this hawthorn is exceedingly useful owing to its sharp thorns. It can be used in conjunction with other plants, such as beech, wild crab, myrobalan or cherry plum (Prunus cerasifera), or briar, but in such combinations care must be exercised not to allow the stronger-growing allies to overcome the quick with too close attention.

Box and yew hedges are so typically English in appearance, so easy to control, shape, trim and train (matters of topiary work), that it is only necessary to refer to them briefly. They are, however, rather inclined to have a depressing effect, and should not be overdone in a large garden. The common yew is also an ideal avenue tree, and, used in conjunction with silver birch, is excellent for the purpose of ornamental avenue work, for short vistas. Both box and yew are greedy feeding plants, and can be much aided by occasional applications of artificial manure, or fresh soil of good class. The golden yew is a beautiful plant for employing for hedge formation. Box must not be pruned in too hard in an attempt to control its growth, or restore lost vigour, for it takes some years to replenish its covering, breaking very reluctantly from the older wood.

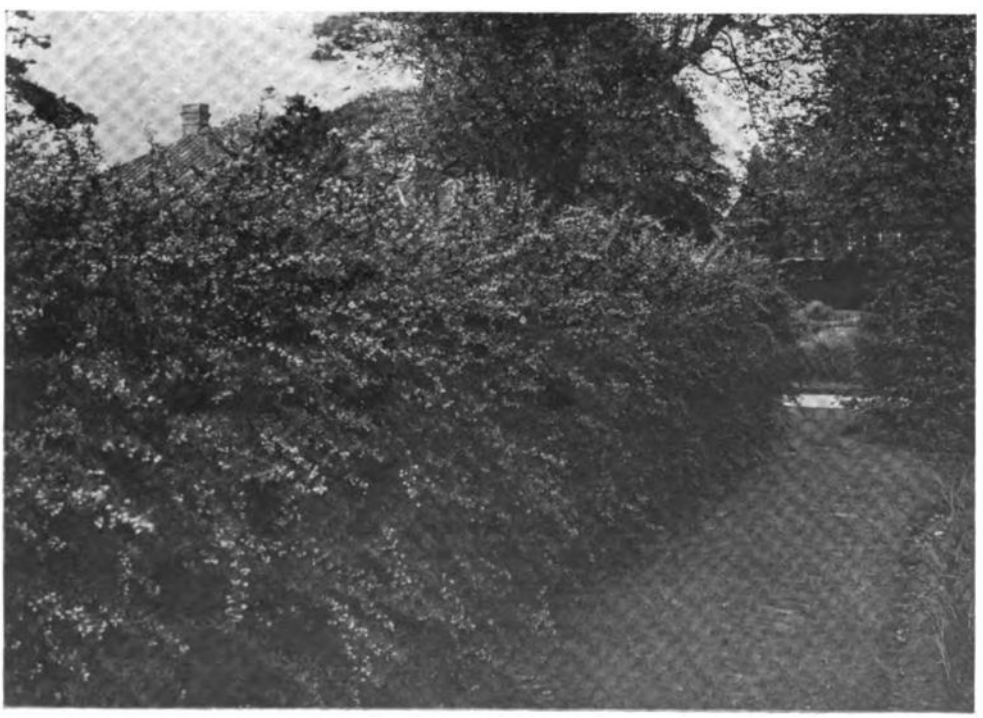
Evergreen or holme oak can be employed for tall screening hedges, but is a difficult plant to move successfully to a new site. Other evergreen subjects forming good shelter, and screens, can be found among the coniferæ, in such families as the cupressus (such as C. Lawsoniana, C. nootkatensis), and thuyas (T. plicata, etc.).

Now for a few of the more interesting ornamental subjects. Americans employ two very formidable plants for protective hedging in Maclura aurantiaca and Ægle sepiaria, the last with its big barbs of growth should be more employed in this country for medium-sized hedges, being very pretty with its white flowers and it is hardy. Cratægus macrantha, too, an American thorn, with spikes 4ins. to 5ins. long, would defy boy, man, or beast in their efforts to break through, besides being most beautiful in flower and fruit; there are many others of the same group that should be tried owing to their possibilities as hedge plants.

Evergreen berberises, other than the Mahonia, should all make fine hedges, and particularly so in the cases of Berberis Darwinii and B. stenophylla. One of the most beautiful hedges I have ever seen was composed of holly and Berberis Darwinii in the proportion of one berberis to six hollies; in the spring this was indeed a lovely sight. Chinese introductions, such as Berberis Sargentiana, B. Julianæ, B. Gapnepainii, to mention only a few of them, should make charming effect, with their foliage and fruit, while B. Hookerii, B. candidula and B. verruculosa, although of slower growth, should prove efficient for medium heights.

Roses, such as those of the Wichuraiana group could well be utilised for the purpose of hedges, where they prove to be at home, and the dwarf Polyantha group make beautiful edging plants for big beds.

In the milder parts of the country hedges can be formed with such plants as olearias, pittosporums and elæagnus, while by the sea the silvery Atriplex halimus, and the beautiful flowering Escallonia species and hybrids are lovely. Cydonia japonica is another instance of a marked success in an ornamental hedge, and we must not overlook the claims of the loniceras of the Xylosteum or bush group, in particular that charming and dainty evergreen, with its small shiny foliage, Lonicera nitida, which assuredly has a great future as a hedge plant.



A HEDGE OF BERBERIS STENOPHYLLA.

Before leaving this section I should like to refer to a matter, which though not strictly hedge work, approximates very closely to it—the question of boundary demarkation. At Aldenham, from which I write, we have employed clipped limes for the purposes of a short avenue, a subject that was illustrated in a contemporary of THE GARDEN—*Country Life*. This idea of clipped trees, where they are cut to straight sides, and tops, in rows, is utilised on the Continent for the demarcation of city squares, and could well be employed for similar uses in this country in the place of uninteresting hedges, such as some of our towns possess, or in the place of posts and chains. This would form a welcome addition as a horticultural feature to some of our public parks and gardens.

I must also dwell on one or two planting details. Double rows of quick are generally planted in the course of hedge formation. I have done this myself occasionally, but have now ceased to

Digitized by Google

employ this method, and only use one single row in close formation. I believe the old method to be faulty, for in the course of time single rows apparently make a far more efficient hedge, doubtless owing to the lower growths getting more air and light.

For damp ground, inclined to get water-logged, hornbeam will be found a most useful medium, as it does not resent this disadvantage so much as many other plants do; while for shallow soils, and especially those of limy nature, beech will be found suitable.

It has only been possible to mention a few of the plants that can be employed for hedges, but they should be sufficient to call attention to the fact that there is a great variety which can be so employed. There is ample scope for enterprising hedge planters to work out and use many more highly useful and ornamental plants than at present.

ALPINES ON THE MONTE MORO PASS

ON my way homewards from the Maritime Alps a few days were spent in and about Lugano, one of the loveliest of the Italian lakes. Although for the most part situate within the Swiss frontier the atmosphere (excepting the recent Frenchified hotels and buildings fronting the lake) is entirely that of Italy: lovely little villages with their typical churches and dainty campaniles—graceful, unobtrusive, and an integral part of the picturesqueness. The presence of buzzards floating about above the lake further enhanced the interest.

After being in the higher Alps, Lugano was found very hot and enervating and not conducive to activity. The very pretty pink-flowered Dianthus Caryophyllus, the parent of the innumerable carnations of the present day, was seen about Lugano, also at Baveno on Maggiore and at Monte Generoso. At Bellagio on Lake Como what appeared to be Erigeron mucronatus (a New Zealand plant) was flowering freely in the walls by the side of the lake. On a track leading up from Bellagio the little yellow-flowered Oxalis corniculata was plentiful in the joints of the cobble paving; a dangerous plant to introduce into the garden, where it is liable to take complete possession.

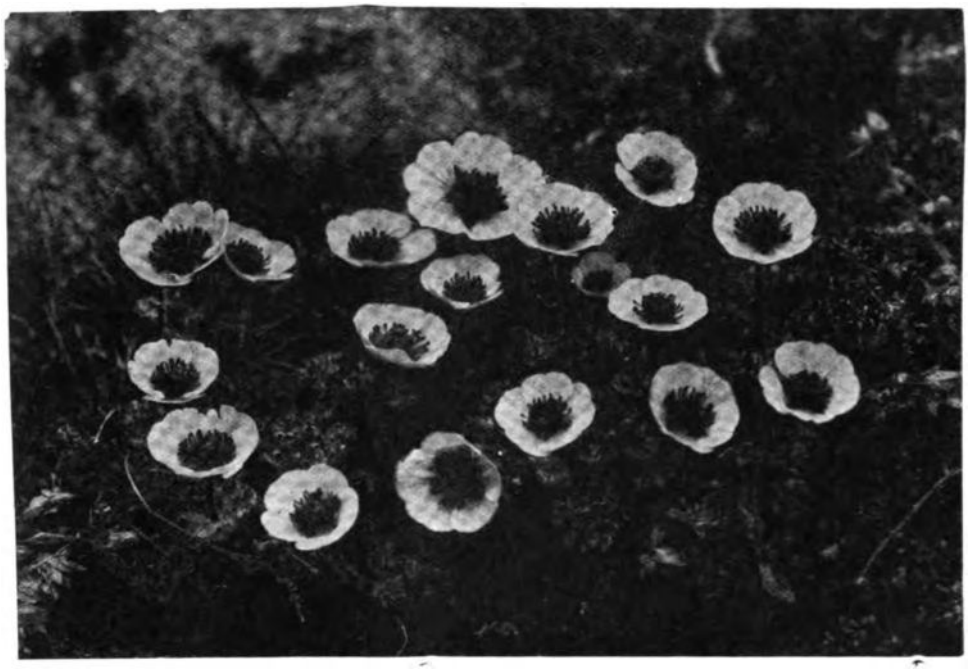
A visit to Monte Generoso proved interesting; although hot and sunny down by the lake, the top of the mountain, some 5,600ft. up, was, unfortunately, enveloped in a cold mist; the distant views, usually very fine, being for the most part obliterated. On the walk up from Bella Vista, the first halting station of the mountain railway, a few plants of interest were noted, including Astrantia minor, Campanula barbata and Dianthus plumarius (white and pink flowered). Nearer the summit, part of which is in Italy and had the usual Italian sentries to protect their rights, Campanula pusilla was very pretty running along in the rock crevices and quite a quantity of Saxifraga Aizoon was in flower on the shady side of the rocks. On the way down by a very steep path to the Lake level the pretty Cyclamen europæum was in flower along with Astrantia major, the Willow Gentian (Gentiana asclepiadia) Dianthus Caryophyllus, besides Corydalis lutea, a beautiful weed difficult to localise if it once gets established in the garden. These cliffs are evidently breeding places of the buzzards, as they were seen sailing gracefully about and their characteristic "mewing" was frequently heard.

Leaving Lugano for Macugnaga on August 3rd by way of Lake Maggiore and Baveno to Vogogna, I motored up the beautiful Val Anzasca to Macugnaga, where the night was spent previous to going over the Monte Moro Pass into Switzerland. Interesting plants noticed *en route* were Dianthus Caryophyllus, Saxifraga stellaris, S. aizoides and S. Cotyledon, the fine rosettes of the last named in the crevices of the rocks along a portion of the road. In a book obtained since my return, entitled "Sketches in Italy, etc.," by J. Addington Symonds, is the following beautiful reference to S. Cotyledon, which he would probably have seen in or near this locality over fifty years ago. "I think that botanists have called it Saxifraga Cotyledon; yet in spite of its long name, it is beautiful and poetic. London Pride is the commonest of all the saxifrages; but the one of which I speak is as different from London Pride as a Plantagenet upon his throne from that last Plantagenet who died obscure and penniless some years ago. It is a great majestic flower, which plumes the granite rocks of Monte Rosa in the spring. At other times you see a little tuft of fleshy leaves set like a cushion on cold ledges and dark places of dripping cliffs. .... But about June it puts forth its power, and from the cushion of pale leaves there springs a strong pink stem, which rises upwards for a while, and then curves down and breaks into a shower of snow-white blossoms. Far away the splendour gleams, hanging like a plume of ostrich feathers from the roof of the rock, waving to the wind, or stooping down to touch the water of the mountain stream that dashes it with dew. The snow at evening glowing with a sunset flush, is not more rosy-pure than this cascade of pendent blossoms. It loves to be alone, inaccessible ledges, chasms where winds combat, or moist caverns overarched near thundering falls, are the places it seeks. I will not compare it to a spirit of the mountains or to a proud lonely soul, for such comparisons desecrate the simplicity of nature, and no simile can add a glory to the flower. It seems to have a conscious life of its own, so large and glorious it is, so sensitive to every breath of air, so nobly placed upon its bending stem, so royal in its solitude. . . . The other day we cut an armful—and then felt like murderers; it was so sad to hold in our hands the triumph of those many patient months, the full expansive life of the flower, the splendour visible from valleys and hill sides, the defenceless creature which had done its best to make the gloomy places of the Alps most beautiful."

After a night's rest in the upper regions of an hotel "dependence," an early start was made on a lovely exhilarating morning in one of the most romantic corners of the Alps, an amphitheatre including the majestic precipitous faces of Monte Rosa with high mountain buttresses on either side, snow capped and lovely in the sunny clear atmosphere.

MATTMARK SEE AND MONTE MORO PASS.

Digitized by Google



THE SILKY-LEAVED VARIETY OF RANUNCULUS GLACIALIS.

The climb up the pass from the Macugnaga side is very steep and rough. On the way up the pretty flowers of Campanula barbata were fairly frequent and Asperula cynanchica was seen in the earliest part of the ascent; but, having a guide to the top of the pass, not much time was allowed for investigation. Fortunately, he was a bit out of condition and required a rest about 7,000ft. up, which gave me an opportunity of looking round a little. It was a pleasant surprise to come across a fine lot of Androsace imbricata in some rock crevices in full sun—a specially welcome find as it was one of the plants in Farrer's list that I had failed to find on the Maritimes. The pretty and very local Campanula excisa also inhabited this level. Primula hirsuta in rocky crevices in seed, and quantities of Campanula pusilla were noted a little earlier, together with Dianthus sylvestris and Dianthus carthusianorum. Pushing on we arrived in a stony basin almost at the top of the Pass between 9 and 10 o'clock. The Pass was snow covered with snow-capped mountain ridges on either side. At this point we came up against the Italian sentries who, on examining my pasport, refused to allow us to proceed owing to it not having been signed by the Brigadier-General in Macugnaga. As the sentries persisted, and had stopped other travellers for the same reason, I had to send the guide down to obtain the required signature. This entailed a wait of over six hours in a stony waste. The snow had quite recently left this level and laid about in patches immediately above. Plant life was just awakening, including Silene acaulis, mostly excarpa, about 9,000ft. up, Gentiana imbricata just coming into flower, Ranunculus glacialis, Saxifraga obtusifolia, S. moschata with yellowish green flowers, Chrysanthemum alpinum and Cherleria sedoides. The guide returned about 4 o'clock, having obtained the required signature. After a rather sharp altercation with the sentries—as far as I could make out from the guide's German-Swiss the sentries had no right to stop us, as he had been told that the signature was unnecessary—we at last got on the way again and were on the top of the Monte Moro Pass, about 9,400ft. high, in a few minutes. For a short time the track was over the snow. A little lower, where the snow was melting rapidly in the hot sun, the water was streaming over the rocks which were carpeted for a considerable distance with Ranunculus glacialis showing its lovely flowers in thousands—white, rose and red, large and small, in bud and fully opened, magnificent, a sight of a lifetime.

T. ASHTON LOFTHOUSE.

(To be continued).

ILLUSTRATED FORECAST of the CHELSEA SHOW

ON Tuesday, May 27th, and the two following days, the great Spring Show of the Royal Horticultural Society will be held in the Chelsea Hospital grounds. It is opportune that this, the world's greatest horticultural show, should be held at this date. The British Empire Exhibition, which was recently opened, has attracted thousands of visitors from distant lands, and it will give them an opportunity of seeing this wonderful flower show at Chelsea.

It is doubtful what particular exhibits are the most popular. However, it does not matter in which direction one's tastes lie, because one will find every conceivable phase of horticulture represented. The rock and water gardens outside always attract a great deal of attention, and the same applies to the formal and informal gardens. Orchids are also a great feature of this Show.

This year Messrs. Sutton and Sons are exhibiting sixty-one beds, each containing a different subject. These beds will consist of greenhouse flowers, hardy and half-hardy annuals. Some of the outstanding greenhouse plants will be begonias, gloxinias, calceolarias, cinerarias, streptocarpuses and the brilliant Clerodendron fallax. Among the annuals will be clarkias, schizanthuses, nemesias, Phlox Drummondii, dimorphotheca, tobacco plants (nicotiana), lobelias and lavateras. The Reading firm are famous for the excellence of their exhibits, and this one promises to be exceptionally attractive.

Messrs. Carter and Co. are putting up a large group of greenhouse plants and hardy and half-hardy annuals. The exhibit will be somewhat rectangular in shape, and round the large bed in the centre will be many other beds of various shapes and sizes. Like the Reading firm, Messrs. Carter will fill each bed with one kind of flower. Ferns will divide each bed, and interspersed throughout the exhibit will be sweet peas and antirrhinums. The exhibit will be surrounded by an edging of grass, the back of this being fringed with a ribbon of myosotis and the front edged with ageratum and small ferns.

Outside, near the Embankment, Messrs. Carter are to construct a fountain garden. Seasonable flowers and shrubs will be employed in this garden, which is to be of simple design.

Florist flowers raised from seed and annuals in pots will comprise the exhibit of Messrs. Edward Webb and Sons. Here will be seen calceolarias, cinerarias, begonias, gloxinias, schizanthuses, nemesias, Dimorphotheca aurantiaca and Rhodanthe maculata.

Messrs. Blackmore and Langdon will stage an exhibit of double begonias, including Hilda Langdon, Lord Lambourne, Mrs. H. Moncrieff and Lady Cory.

Among basket begonias will be seen such varieties as Stella, Venus and Lena. Messrs. Blackmore and Langdon will also stage a large variety of their well known delphiniums, including such as Rev. E. Lascelles, Mrs. Shirley, Millicent Blackmore, Walter T. Ware, and their 1924 novelty Fairy Queen.

Messrs. Allwood Brothers will stage an extensive exhibit of perpetual-flowering carnations, comprising 600 dozen blooms. The flowers will be arranged in four large bays, and the background will consist of palms and ferns. Such well known sorts as George Allwood (pink), White Pearl, Wivelsfield Apricot, Laddie (pink) and the yellow malmaison, Jessie Allwood.

Adjacent to this exhibit Messrs. Allwoods will construct a carnation garden, consisting of their well known Dianthus Allwoodii and new perpetual-flowering border carnations. Among the new Allwoodii will be Beatrice (deep salmon), Elizabeth (blush salmon), Freda (pale mauve). The new perpetual border carnations include Sussex Beauty (heliotrope), Sussex Supreme (blush salmon), Sussex Purple and Sussex Pink.

Mr. C. H. Herbert of Dianthus Herbertii fame will stage some of his beautiful pinks.

Messrs. Andrew Ireland and Hitchcock will exhibit over 5,000 sweet pea blooms, including many new varieties and some unnamed seedlings. They will also show Dianthus Mascott, which is a hybrid between the Sweet William Scarlet Beauty and the single carnation. This plant has the scent of a carnation and in habit is similar to a sweet william. The large flowers are borne in trusses and are pink in colour.

Messrs. Keith Luxford and Co. will exhibit perpetual-flowering carnations in many varieties.

Mr. James Douglas is showing his famous cloves and auriculas. The cloves are noted for their dwarf habit, stout stems and perfect calyces. Among the sorts to be shown will be Wonder Clove, Kelso, White Clove, Scarlet Clove, Viceroy and Bookham Belle.

Messrs. Reamsbottom and Co. are exhibiting the popular St. Brigid anemones in many hues.

Lupinus polyphyllus in many varieties will be staged by Mr. G. R. Downer.

Messrs. Jarman and Co. will stage zonal pelargoniums, including their new Edward Hockey, Cedric and Adonis. They will, in addition, show rock violas in many varieties, including Velvet Queen, Golden Spur (yellow), Moonlight (pale lavender) and Heavenly Blue. Centaureas The Bride, The Bridegroom, Bridesmaid and Honeymoon will also form part of this exhibit.

Roses are always in evidence at Chelsea. Messrs. B. R. Cant and Sons will show their new roses, including Lady Roundway (Pern., deep coppery chrome), Phœbe (H.T., cream white), Rev. F. Page-Roberts (H.T., yellow), Mrs. Oakley Fisher (H.T., orange yellow) and Padre (H.T., coppery scarlet).

Messrs. Chaplin Brothers are showing a large group of roses in pots, consisting of tall pillar roses, standards and bush trees. Many new and popular varieties will be exhibited, as well as some of the older and well tried kinds.

Mr. Elisha Hicks will stage, among many of the old and new varieties, such sorts as America, Clovelly, Dorothy Dix, and Double Orleans, also many of the newer ramblers. Altogether, Mr. Hicks will be staging about 1,000 pot roses.

Messrs. Frank Cant and Co. will exhibit several seedling roses, together with well known varieties. This firm will include in their exhibit Capt. F. S. Harvey-Cant (H.T., rich salmon pink veined with scarlet and suffused with yellow), Henry Nevard (H.T., crimson scarlet) and Mrs. Alfred West (H.T., shrimp pink).

Pyrethrums and new hybrid lupins will be staged by Messrs. Kelway and Son. Such varieties as Langport Scarlet, Aphrodite, James Kelway and Agnes Mary Kelway will be shown. These plants are absolutely hardy, and invaluable for cutting purposes.

Messrs. Kelway's hybrid lupins are the result of crosses of L. polyphyllus with L. arboreus. These plants are wonderfully fragrant.

WEBB'S EXHIBITION GLOXINIA.

From the Orpington Nurseries will come a large number of flowering shrubs, consisting of rhododendrons, azaleas, acers, cytisuses, etc. They also hope to stage an exhibit of irises. It is rather doubtful whether irises will be numerous this year owing to the unfavourable weather experienced in this country of late.

Rock plants are always popular at Chelsea. Messrs. Maxwell and Beale will show Primulas Bulleyana, Aileen Aroon and luteola. Other noteworthy plants will include Dryas Sundermanii, Saxifraga cochlearis lingulata, S. bronchialis and their new S. hybrida Esther (S. cochlearis lingulata × S. Aizoon lutea). This plant has the habit of the former and the colour of the latter, and it is very free flowering.

Dr. Macwatt is exhibiting many new and rare primulas, such as PP. anisodora, cyanantha, chrysopa and the excellent hybrid, Linda Pope. Dr. Macwatt also hopes to stage alpine, show and double auriculas.

Messrs. Storrie and Storrie will show long-spurred columbines, auriculas, cowslips and polyanthuses in colour groups. They will also exhibit their Excelsior Iceland Poppies in new shades.

Messrs. William Cutbush and Son, Limited, are putting up a large group of roses, comprising polyanthas, ramblers grown as tall bushes and standard weepers. The principal sorts will be Orange King (new), Salmon Queen, Baby Faraulx, Girlie, Mrs. Cutbush and Orleans. In close proximity to the roses will be a group of flowering plants mainly composed of hydrangeas.

Outside in the grounds Messrs. Cutbush will have an exhibit of choice rock plants, including shrubs and ferns suitable for the rock garden. They will also have an extensive exhibit of clipped trees, including bays.

A FINE HOUSEFUL OF SCHIZANTHUS (MESSRS. SUTTON'S STRAIN).

Digitized by Google

Strawberries growing in pots as well as gathered fruit will be staged by Messrs. Laxton Brothers. In their exhibit Messrs. Laxtons will show their new Strawberry Majestic, which is a main-crop variety with large, firm fruits. They will also stage their last year's novelty, Abundance, together with such well known sorts as The Duke, Sir Douglas Haig, Lord Beatty and King George.

Violas of the show, bedding and gracilis types are to be shown by Mr. William Yandell in trays. Among the show varieties will be George MacDonald (primrose), William Barr (white), Annie Hamilton (glossy black, shaded lavender). Bedding varieties will consist of such sorts as Bridal Morn, Mauve Queen, the popular Maggie Mott, Moseley Perfection and Queen of Whites. The gracilis varieties will comprise Leonard Marshall, Purple Robe and Clarence Elliott.

About seventy-five dishes of apples and pears will be exhibited by Messrs. George Bunyard and Co. These fruits have not been kept in cold storage, and no artificial means have been employed to keep this fruit, beyond a thatched fruit store with an earthen floor.

Messrs. Bunyard will also show an exhibit of irises, including many of the newer varieties, such as Ambassadeur, Mme. Gaudichau, Magnifica, Raffet, Vanessa, Viking, Rotuna and the beautiful Hoogiana.

Irises, tulips (including a few novelties) and pyrethrums will be staged by Messrs. R. H. Bath, Limited.

A large group of pot and cut roses will be shown by Messrs. A. J. and C. Allen. The exhibit will have a background consisting of large specimen ramblers of Romeo, Chatillon Rambler and White Dorothy, also standards on rugosa stock of Golden Emblem, Golden Ophelia, etc. The groundwork will comprise polyantha roses, including Reine Elizabeth and Orange King, the latter being a sport from Jessie. The new Wichuraiana Albertini will also be shown. It is dark vermilion in bud, opening to shaded copper. Mrs. Beckwith, which is a lemon yellow Pernettiana, will be shown in quantity.

Messrs. John Waterer, Sons and Crisp, Limited, will show herbaceous plants, conspicuous among which will be their hybrid lupins, including Mayflower (porcelain and pale blue), Dresden China (soft French grey) and Fascination (rosy violet and lavender).

Irises and delphiniums will also be shown by this firm, besides rhododendrons; among the latter will be the popular Pink Pearl, Alice, Sweet Simplicity, Corona and Diphole Pink.

A formal walled garden will be constructed by Messrs. R. Tucker and Sons, outdoors. This firm will also put up a small rockery in one of the tents and a representative collection of alpines and herbaceous plants will be on view.

Messrs. Pulham and Sons will endeavour to depict a piece of old Westmorland scenery. Westmorland water-worn limestone will be employed, and a streamlet will run from the highest point over a miniature fall, finally discharging into a small pool in the lowest part.

Features of the exhibit are to be turf glades with outcrops of stone in the foreground. The background of the exhibit will comprise various evergreen and flowering shrubs, and the rocks will be clothed in the crevices and pockets with alpines and shrubs.

Messrs. Pulham will also have in one of the tents an exhibit of rock plants and shrubs.

Irises, lilies, rhododendrons, azaleas and Japanese maples are to be shown by Messrs. Wallace and Co. Among the irises will be the new Pioneer (a red purple), Duke of Bedford, Citronella, Bruno and many older forms. Among the lilies the Backhouse hybrids promise to be conspicuous.

May-flowering tulips in great variety will be shown by Messrs. Barr and Sons. This firm will also have a very representative exhibit of herbaceous plants, rock and alpine plants.

A small sunken formal garden, constructed of Yorkshire stone and planted with alpine plants and flowering shrubs, will be exhibited by Messrs. Kent and Brydon.

Mr. J. C. Allgrove will show flowering shrubs, herbaceous and alpine plants in great variety.

A large collection of hydrangeas is to be shown by Mr. H. J. Jones.

Alpines and dwarf shrubs will be exhibited by Messrs. Bowell and Skarratt.

Fruit trees in pots will be exhibited by Messrs. Rivers and Son. These will comprise peaches and nectarines.

Pot-grown dahlias and a large selection of violas and alpines will be shown by Messrs. Carter Page and Co.

East Lothian stocks, auriculas, pansies and dahlias will be exhibited by Messrs. John Forbes and Co.

Himalayan and other rhododendrons, new and rare shrubs and giant poppy anemones will be exhibited by Messrs. R. Gill and Son.

A FIELD OF MR. DOWNER'S HYBRID LUPINS.

A vast collection of orchids, including innumerable odontoglossums, odontiodas, cymbidiums, cattleyas and læliocattleyas will be shown by Messrs. Charlesworth and Co. Messrs. Cypher and Sons will also show orchids.

Messrs. Gaze, of Kingston-on-Thames, are exhibiting a garden planned on original and distinctly formal lines investing it with an attractiveness peculiarly its own. A pool in a sunken section of the garden is to be a feature and will be surrounded by a floral terrace. On one side the garden is to be enclosed by yew hedges. Entered through a flower walk with a path of stepping stones, at the extreme end will be seen an old iron gate set between stone piers, and the whole should form a garden of unusual beauty combined with a restful simplicity.

A formal garden will be arranged by Messrs. J. Cheal and Sons. At one end a kitchen garden is to be constructed, in which trained fruit trees will be placed. This will, of course, be screened from the other part of the formal garden, which promises to be very attractive. Apart from this garden, Messrs. Cheals are to exhibit dahlias, plants for which they are justly famed. It was this firm who introduced the now very popular Star section. Representative groups of alpines and shrubs will also be shown.

Mr. Wood, of Ashtead, is to construct a rock garden; on tabling in it he will exhibit numerous alpines. Mr. Wood also hopes to exhibit a large batch of Pentstemon Scouleri.

Apart from the floral side there will be an enormous number of horticultural sundries, such as insecticides, ladders, spraying machines, mowing machines, etc.

NOTES ON PRIMULAS

BY DR. MACWATT.

(*Continued from page 332.*)

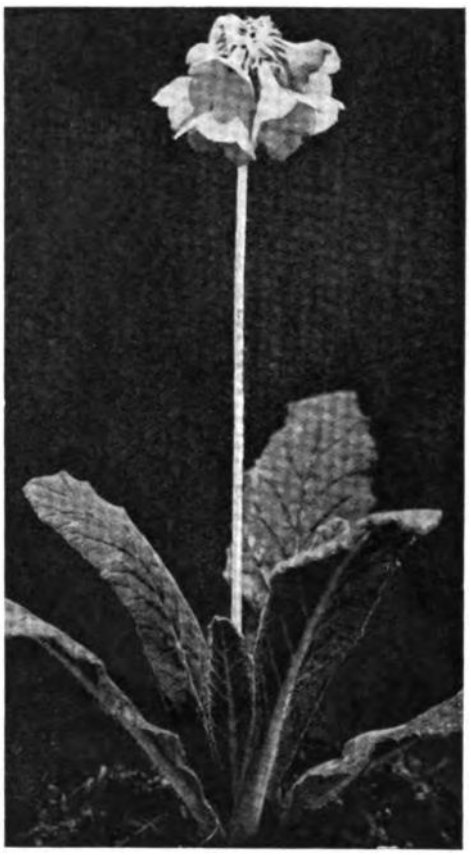
PRIMULA Giraldiana, sent out under the name of P. muscaroides, makes a nice plant with purple flowers in drooping heads. P. conica bears a strong resemblance to it, but has a hairy scape, and flowers that range in colour from lilac to pure white. P. deflexa is a beautiful and fragrant species with flowers of a particularly pleasing shade of blue.

P. pinnatifida, although it comes from the limit of perpetual snow, is not hardy in our climate. It produces, on stems about 6ins. in height fragrant, pendent flowers of a lavender colour. Its foliage is sometimes so much laciniated as to render the plant almost unrecognisable; it is a remarkable fact that it does not display this characteristic in the cultivated state.

P. nutans has large lavender flowers in dense heads on white mealy stems, the flowers being also covered with meal. It is best to grow this variety under glass.

A group of primulas characterised by rounded heads of blue flowers includes PP. capitata, cristata, Mooreana, pseudo-capitata, and sphærocephala. The two last named are natives of China; the others are natives of the Himalaya mountains. PP. pseudo-capitata and sphærocephala while displaying minor differences may be distinguished from the Himalayan forms by their smaller coralla-limb and more globular heads of flowers. Of the group, P. Mooreana is much the best as a garden plant. It has fine foliage, bright green above and covered with white meal on the under surface. P. sphærocephala has rather larger flowers than its sister species, P. pseudo-capitata.

P. rupicola.—I had the pleasure of exhibiting this fine primula at Chelsea in 1923, when it was greatly admired by everyone and a good illustration of it appeared in THE GARDEN the same year. Its native place in Yunnan, where it grows at an altitude of 12,000ft. on boulders and stony pastures. It grows from 3ins. to 8ins. in height and its colour has been described as rose with a yellow eye, but the plant which I exhibited and which, unfortunately, I have since lost had very beautiful mauve flowers. It is one of the extremely mealy primulas. This very fine species is, unhappily, not in commerce.



PRIMULA NUTANS, IDEAL FOR THE ALPINE HOUSE.

P. pseudo-sikkimensis is the Chinese dwarf limestone form of the well known Himalayan primula, P. sikkimensis. It bears fine yellow drooping flowers with a white centre. P. flexilipes may be described as a miniature sikkimensis and may therefore be of value to those who prefer a smaller plant. Its leaves are short, almost rounded, while the leaves of sikkimensis are winged practically to the base.

P. pulchella was introduced from Western China and sent out by Messrs. Bees in 1911. It has denticulated, leathery leaves 4ins. to 6ins. long covered with golden meal below. The flower stem carries a truss of six or more large beautiful deep blue flowers. It is a superior plant in every way to P. pulchelloides, introduced in the same year and from the same district, and which has smaller leaves and flowers which are more lilac than blue.

P. chionantha.—While the two varieties just described are difficult to keep in this country, we have in P. chionantha a species which promises to become quite a popular garden plant. I have seen it growing and flowering in great perfection on the open rockery of Miss Brown at Longformacus in one of the coldest of situations in the Lammermoors. It bears stout stems from 12ins. to 20ins. in height, on which are carried whorls of lovely fragrant ivory-white flowers, each about 1in. across.

P. sino-purpurea, a native of Yunnan, where it was found by Forrest growing at an altitude of 12,000ft., is another very fine species. It has large dark green leaves coated beneath with yellow meal, as is the flower stem, which may attain the height of 18ins. to 20ins. The flowers are rosy-purple with a grey eye, and about 1in. across, and as they are produced in large trusses, the plant when in bloom has a most striking appearance.

P. Maximowiczii.—The flowers of this North China species are small and of a brownish-red colour, and it cannot be said to be a particularly attractive plant. Moreover, it has the disadvantage of requiring to be grown under protection.

P. vincæflora.—I have had the pleasure of exhibiting this species at Chelsea on several occasions. It is distinguished by the possession of one solitary flower carried directed obliquely downward on a stout scape which gradually lengthens till it becomes double its original length. The flower is violet with a deeply tinted eye and stamens with long filaments.

P. membranifolia and P. yunnanensis much resemble each other, but the leaves of the latter are smaller and more finely cut. Both are said to be delightfully fragrant in a state of nature, but in cultivation I found no trace of this. Both produce flowers of a pleasing shade of lilac-purple with a white eye, in small umbels. The flowers of P. membranifolia are quite small when they open, but gradually enlarge until they almost double their size.

P. glycosma.—This primula is much like P. Poisonii and is strongly scented of aniseed. It is only moderately hardy. The flowers are crimson with a golden eye.

P. helodoxa.—One of the best of recent introductions. Much of the plant is covered with golden farina and its stately scapes attain the height of from 2ft. to 3ft. The flowers which are produced in whorls are sulphur yellow in colour and pendent. It bears a strong resemblance to P. Smithiana, a Himalayan species, but in some ways is quite distinct. P. Smithiana is a smaller plant. In P. helodoxa the calyx is more reflexed, the corolla much longer and the flowers of a deeper yellow. The young flowers of P. Smithiana are deeply tinged green, a feature absent in P. helodoxa.

P. chungensis is closely related to P. Cockburniana and P. Bulleyana, two very well known primulas. It produces whorls of beautiful deep orange-yellow flowers which are sweetly scented. It has been called a yellow Cockburniana on account of the resemblance of its foliage to that plant, and many of the plants sent out under the designation of P. chungensis are simply P. Cockburniana. I question very much if the genuine plant is in commerce at the present time.

Digitized by Google

P. serratifolia.—The coloration of the flowers of this plant is most remarkable, the outside being pale yellow, while the centre has a dark blotch. If an ordinary photograph of the flower is taken, this characteristic is even better seen, as the dark patch shows up like a black band.

P. anisidora, as the name implies, has a strong odour of aniseed which is emitted by all its parts and is much more pronounced than in the case of P. glycosma. Its flowers are deep plum purple, almost black and have been likened to a brown auricula with a yellow eye.

JAPANESE PRIMULAS.

Eleven species of primula come to us from Japan, or including microforms, fourteen. It is noteworthy that none of these is found in China. We are so accustomed to link China and Japan together that it is difficult for us sometimes to realise that their floras are so completely dissimilar as they are.

At the head of the list must be put P. japonica. This well known garden plant was introduced at least fifty years ago by Mr. William Bull and is so familiar as to require no description here. It is deservedly popular on account of the beautiful colours of many of the garden forms and lends itself readily to naturalisation, making a magnificent show when grouped. The colours range from deep purple to rose-pink and almost to white; but even in the purest whites there is always a coloured ring round the eye.

P. Sieboldii is not quite so hardy as P. japonica, and one is apt to lose it in winter. The cultivated forms range in colour from white to rose and purple.

P. Reinii, possibly introduced to cultivation by the Yokohama Nursery Co., is a good little plant with soft pink flowers which are large for its size. Unfortunately, it is not quite hardy, but can be kept well under protection.

AMERICAN PRIMULAS.

The Western Hemisphere is not rich in primulas. The three American species which are of interest from the gardeners' point of view are P. Parryi, P. Rusbyi and P. suffrutescens.

THE VIOLET COLOURED P. VINCÆFLORA.

The first named is a native of brook-sides in the Rocky mountains. Coming from such an elevation one would anticipate that it would be easy to grow, but most cultivators find that the contrary is the case. Personally, I have it growing in a rose border not exposed to the direct rays of the sun and in good rich soil, where it bears attractive umbels of bright purple flowers on long scapes.

P. Rusbyi.—I find that I cannot grow this plant in the open air, but it succeeds with me plunged in pots among ashes in a cool house. Its flowers are crimson purple nodding to one side, and have a deep, irregular line round the yellow throat of the corolla, while the calyx is prettily striped with white meal.

P. suffrutescens, from the Sierra Nevada, is a sub-shrubby species and fairly hardy in sheltered, well drained places on a rockery. It is quite like a dwarf shrub, with dark foliage and pink flowers. Apparently owing to the way in which its branches rest on the ground they are apt to rot off in the winter. It can be readily raised from seed or propagated by layers or cuttings. In its peculiar habit it is most distinct from any other member of the group.

A USEFUL AND HARDY SPECIES, P. INVOLUCRATA.

HIMALAYAN PRIMULAS.

Returning to the Eastern Hemisphere, we find that the Himalayas yield us quite a few fine species of primulas. One cannot deal with the primulas from this region without mentioning P. Reidii and P. Wattii.

The first named comes from the Western Himalayas and bears beautiful fragrant creamy-white flowers, carried on short mealy stems well above the densely hairy leaves. It is quite a gem, one of the most delightful of primroses, and seeds easily.

P. Wattii is another very fine primula with bright green leaves, bronzy-hued scapes, and clusters of drooping purple flowers. The

Digitized by Google

unopened flowers are the same colour as the scapes. The flowers have a broad eye of white meal which is not visible unless looked at from below. It was introduced under the name of P. Gilli. Both this species and the last named are sensitive to our damp climate in winter and I am afraid that P. Wattii at the present time is not in commerce.

P. mollis, a Himalayan primula with small flowers, is chiefly grown for its attractive foliage. Its large lobed heart-shaped leaves have their margins watered, notched and roughly toothed; their soft texture and rich green ribs densely covered with hairs give the plant a most striking appearance. The calyx is an intense red colour; the corola is rose.

P. Menziesiana keeps green the memory of a member of the staff of the Royal Botanic Gardens, Edinburgh, who fell in the Great War. It is found in sandy crevices and rocky ledges in Bhutan. It has hairy leaves and light blue, sweetly scented flowers and in cultivation will be found to resent surface moisture in winter.

Mention may also be made of P. burmanica, which as its name indicates. is a native of Burmah, where it was collected by Mr. Kingdon Ward. Its flowers are reddish-purple. Coming from a warm climate it can only be expected to be moderately hardy and it is not of much value as a garden plant.

Some members of the section which includes the well known P. involucrata may also be noted. P. involucrata is a most useful and hardy species and where conditions are favourable increases rapidly. It is a native of the Himalayas and bears umbels of white flowers, produced very early in the year. P. Wardii is its West China form, differing principally in the colour of its flowers, which are light mauve. Being quite hardy it is a valuable garden plant. Equally robust, and, indeed difficult to differentiate, is P. sibirica, the flowers of which are rose or bluish.

P. chrysopa resembles the two foregoing in habit, and though quite hardy is seen to most advantage when flowered under glass, as the farina does not then get washed off by rain. Its flowers are of a fine lilac colour and delightfully fragrant.

P. conspersa, discovered by Mr. Purdom in the Chinese province of Kansu and sent out by Messrs. Veitch and Son in 1913, I consider a primula of great merit. It bears whorls of pale lilac flowers on stems about a foot high and seems thoroughly hardy.

P. REIDII WHICH BEARS BEAUTIFUL FRAGRANT CREAMY WHITE FLOWERS.

THE HARDINESS OF SHRUBS

SO many doubts have of late been cast on the hardiness of some of the flowering shrubs introduced in recent years that the results after the past winter may be of some interest.

Although not so severe as the winters of some record years, the past six months have been remarkable for the continuity of the cold weather. There have been no periods of genial warmth, and in this part of the country we had in the early part of this year as many as forty-two nights during which frost of 5° to over 20° was registered. In some respects this continuity of frost was an advantage, the plants showing no inclination to start into early growth, as often happens after a longish spell of mild weather. Another advantage during the past winter was the absence of rain during the cold weather; the plants therefore did not have to suffer from ice on their stems and foliage. On the other hand, the winds were very cold, mostly from the north or east and often very strong. These gardens have important advantages in the shape of high walls and a light soil. Many plants which survived would probably have been killed if they had been grown in the open and been exposed to the full wind. Although most of the plants mentioned below were quite young and had not yet had an opportunity of making much hard wood, they were all carefully planted in prepared leaf-mould and sand. I am a great believer in this compost for young plants, and find that they make many more fibrous roots in it and are thus much more resistant than when planted in ordinary soil.

Among the older shrubs Choisya ternata on east as well as on west walls was hardly touched, only the tips of some of the youngest growths being killed. Escallonia montevidensis on a south wall lost many leaves, but the plant is quite sound. Buddleia Colvilei is uninjured, but Ceanothus rigidus, very small, on a west wall has been killed. On the other hand, Acacia dealbata on the same wall, only protected by a little straw on the main stems, is practically uninjured and has even had a few flowers; this plant is a seedling of my own, three years old and 14ft. high. Acacia Baileyana on an east wall, also three years old, was killed outright, as was Grevillea rosmarinifolia on a south wall, while its neighbour, Grevillea sulphurea, shows no sign of injury. The other losses on the same south wall were Jasminum primulinum and Fremontia californica, both of which continued to grow (and the latter to flower) till the frosts killed the youngest shoots and eventually the whole plant. In the open I lost Correa alba, Olearia Gunniana, Veronica Balfouriana, and on a south wall Pittosporum Tobira. The following among the less hardy were untouched. In the open:

Eucryphia cordifolia
Corokia buddleioides
Corokia virgata
Corokia Cotoneaster
Coriaria japonica
Notospartium Carmichaeliæ
Olearia nummularifolia
Olearia nitida
Olearia myrsinoides Erubescens
Magnolia Wilsonii
Helichrysum antennarium
Veronica epacridea
VV. Colensoi, monticola, Godefroyæ and glaucescens
Viburnum Davidii
Viburnum propinquum
Raphiolepsis ovata and R. japonica
Caryopteris tangutica

Digitized by Google

Caryopteris Mastacanthus
Indigofera decora alba
Halesia tetraptera.
Ceratostigma Griffithii, cut to the ground but growing again from the base.

The following on a south wall came through the winter practically uninjured :

Indigofera Gerardiana
Indigofera Potanii
Lonicera etrusca superba
Punica Granatum fl. pl.
Carpenteria californica
Escallonia organensis
Sophora tetraptera
Lippia chamædryfolia
Billardiera longifolia
Styrax Wilsonii
Cæsalpinia japonica
Hoheria populnea lanceolata
Akebia quinata fl. pl.
Coronilla glauca
Leptospermum scoparium Nicholii

Dendromecon rigidum, however, lost its shoots, although the plant is alive and is beginning to show new growths from the base. On an east wall Tricuspidaria dependens is untouched, and T. lanceolata has had a few of its growths killed, while Desfontainea spinosa and Lomatia ferruginea look as healthy and strong as ever.

Some of my older shrubs, such as Dipelta floribunda, Exochorda Giraldii and E. Alberti on a west wall are really quite hardy and need no protection. Anyhow, the two former show flowers on nearly every shoot and should be a fine sight within the next fortnight.

On balance, I consider that most of the shrubs have passed through the ordeal very satisfactorily and much better than I expected at one time. If the plants had been older I think that the losses would have been even less, but last summer was very cold till July and the new growths had not really ripened before the frosts came early in November.

Herts. ALBERT PAM.

FRUIT CULTIVATION IN SCOTLAND

THERE is no doubt that gardeners in the past—say up to a quarter of a century ago—were past-masters in the art of training fruit trees. We of the younger generation should therefore study with steady eye the beautifully trained trees, especially pears, the branches of which are placed almost with perfect precision at regular distances apart, both in horizontal and fan-trained fashion, on the high brick walls which enclose many of the fine old gardens of our honoured country's lairds. I feel delighted not only at having seen such fine old trained trees, but also in having had the privilege to have worked in gardens where such trees were grown. We might hear a murmur among the present generation of horticulturists that such training of trees now is out of date. That may be so, but let us give honour to the past—and older—members of our craft for the firm foundations they have left us to build upon.

By planting cordon trees to clothe the walls we might be termed up to date, and no doubt there is a great deal to be said in favour of such a practice. The benefits to be had in planting cordons are many. The walls can be clad in less time, with a greater number of varieties—which if judiciously chosen is rather to be commended—as observant practical and scientific men tell us that certain varieties of fruit trees are self-sterile with their own pollen, while others are self-fertile. It is obvious therefore if we grow a fair number of varieties we shall get fruit crops, provided other conditions are favourable.

In an apple flower there are from fifteen to nineteen stamens and five styles, and from one to three anthers are ready to shed pollen at the same time. I once applied pollen of Irish Peach—given as a self-fertile variety—to a James Grieve flower. Fertilisation seemed to have been successful, as the embryo fruit did swell between May 27th—the date of pollination—and June 10th, a period of fourteen days, but afterwards the tiny fruit fell off.

It is said that "apples can be grown upon soil capable of producing agricultural crops, and if the situation is under 300ft. above sea level with full exposure to the sun the prospects of success would be assured."

In my experience I have seen good crops of fine-sized fruits produced on apple and pear trees, and on all small fruits, growing on a situation well over 500ft. above sea level. The soil was of a heavy nature overlying a cold boulder clay, and the situation somewhat exposed.

The old standard apple and pear trees —somewhere I should say between thirty and fifty years old—bore heavy crops of fruit. Lamb Abbey Pearmain was one of the apple trees. This variety is mentioned by the famous McIntosh, at one time gardener at Dalkeith Palace, in his "Practical Gardener," published over eighty years ago. He states that it originated in this country from a seed of Newton Pippin. Cockle Pippin was another of the trees which produced large numbers of medium-sized nicely coloured apples. This variety is also mentioned by McIntosh. The small fruit plantations contained mostly all old plants, which did well, and especially the black currant bushes—over thirty years old. They produced large crops of fine fruit.

The three year old strawberry plants of Royal Sovereign gave a good crop, and fruits were ready for picking on July 8th, and the variety Keen's Seedling produced large berries, which were ready for pulling ten days later. Raspberries did not grow tall or produce robust canes, but they fruited well. The following varieties of apples grown and trained to the west wall fruited splendidly : Cox's Orange Pippin, James Grieve, Stamford Pippin, Winter Peach and Yellow Ingestre, dessert ; Ecklinville, Loddington Seedling, Lord Grosvenor and Lord Suffield, culinary. On the same wall were a cherry tree which fruited well, and a plum tree which flowered splendidly, but seemed to need an affinity, as only an occasional fruit was produced. There is no doubt that very fine fruits of both culinary and dessert apples are grown in Midlothian.

Colour and flavour must be to a certain extent inherent characters, as one can prove by growing different varieties. Irish Peach, Mr. Gladstone, Winter Peach, Worcester Pearmain, Beauty of Kent and Mère de Ménage take on bright colours, while other varieties are yellowish or some shade of green, and all kinds may be grown, and indeed are grown quite near each other, in the same garden.

However, if Worcester Pearmain is grown in heavy soil and on grassland and in a partially shaded situation over 500ft. above sea level, it certainly lacks the nice red colour and does not seem to have quite the same flavour as those grown in a sunny aspect and in better soil.

In this garden, which is several miles nearer the east coast and situated somewhere between 300ft. and 400ft. above sea level, apples, apricots, cherries, pears, plums and all small fruits do well.

The soil is medium heavy overlying clay. Pear trees on the walls, both cordon and other trained forms, produce good crops. Beurré d'Amanlis, Doyenne Bussock, Dr. Jules Guyot, Jargonelle, Louise Bonne of Jersey, Pitmaston Duchess and Williams' Bon Chrétien are among the free-bearing varieties. Strawberries I find do splendidly for two and three years. One year old plants produce the largest fruits, and from them as a rule we pick the first ripe fruit. In 1921 the first ripe fruits were picked on June 27th. In 1922 not until July 10th, while last year none was ready for picking until July 20th, which is only a few days behind the first picking in 1920.

Our one year old plants did not prove so successful last year as in the two previous years mentioned, *e.g.*, 1921 and 1922, and we had to rely on the two and three year old plantations, which were white with flowers on June 14th. The variety on which these observations were made is called Cropper.

It may interest readers to know about our cultural details. Early in July we select and sever from the plantations the runners we require. These are set out in lines fairly close together in a cold frame and receive a thorough good watering. The frame is kept closed and the runners occasionally sprayed and kept shaded from bright sunshine for two or three weeks. After that time they are gradually aired until they are fairly hardened, then we remove the lights entirely. About the end of August the young plants are taken from the frame and set out in the open ground.

Midlothian. DAVID ARMSTRONG.

THE PRE-CHELSEA SHOW

THERE was a slight feeling of uncertainty at the Fortnightly Show of the Royal Horticultural Society at Vincent Square held on May 13th and 14th. What with bad weather behind them and Chelsea in front of them, it is surprising that the exhibits were so good. After all in this most uncertain year a great deal of ingenuity has had to be exercised in order to make flowering time coincide with the shows, and with a constant eye on Chelsea it must have been extraordinarily difficult to arrange good exhibits at this fortnightly meeting. Although the stands were as bright as usual, there was a slight monotony about the exhibits.

There was one exception and that was the magnificent exhibit of Hippeastrums shown by Sir George Holford, which well deserved the gold medal presented by the Society. There are no flowers which give such rich shades of crimson and vermilions. The size of the flowers shown can be judged from the accompanying illustration and their cultivation in this instance is beyond all praise. It does infinite credit to Sir George Holford and his gardener, Mr. Clark. The most notable strains among them were the crimsons and vermilions and we noticed particularly Macbeth, vermilion-scarlet; Dick Turpin, scarlet, with a peculiar satin sheen; Brian Boru, brilliant scarlet; Cardinal Buton, Couleur Cardinal, and so on. The whites were also excellent, but it is a pity that it is so difficult to get away from the diffused green around the throat.

The Hon. Vicary Gibbs had a most enticing exhibit of Gardenia floribunda and the shapely bushes were a great credit to Mr. Beckett. The bushes were symmetrical and filled with buds. This old favourite is not so often seen as it might be, for few flowers have such a scent or perfection of form as a well grown gardenia.

A WELL FLOWERED PLANT OF PHLOX DOUGLASI.

Another attractive exhibit was that of Mr. William Yandell's violas. These were exceptionally well shown, among them being such favourites as Moseley Perfection, bright yellow; W. H. Woodgate, blue-grey; and Admiration, purple. They all showed purity of strain and are invaluable plants for summer borders. Admiration is a great favourite for planting in beds containing white or yellow roses.

Messrs. Bunyard had some excellent vases of Regelio-Cyclus irises on their stand. We are told that these were cut from plants whose bulbs had not been lifted for four years, so it appears that in some soils lifting is not a necessity. The two best of this form of iris are undoubtedly Osiris and its darker form, Isis.

Messrs. Stuart Low Company. showed perpetual-flowering carnations, acacias and their new rose, Roselandia, which is a yellow sport from Golden Ophelia.

Perpetual-flowering carnations and Dianthus Allwoodii were exhibited by Messrs. Allwood Bros. Mr. Englemann also showed perpetual-flowering carnations.

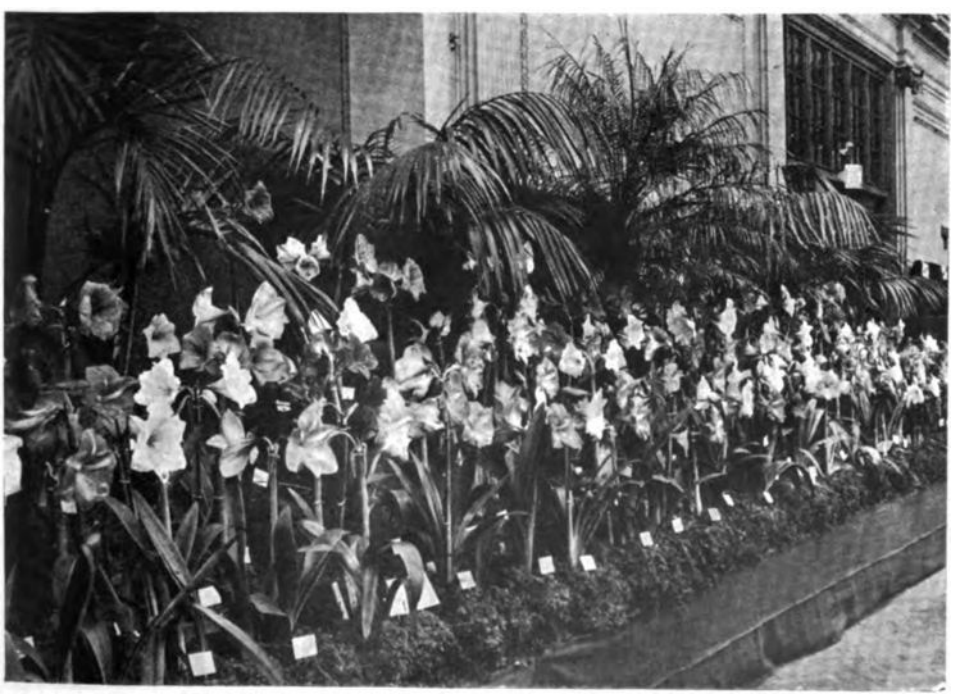
Alpines were numerous and Mr. Clarence Elliott included in his exhibit a brilliant patch of Gentiana Gentianella and a good pan of that little gem Androsace arachnoidea. Messrs. Gavin Jones and Ingwersen also had a good lot of the Gentianella.

Alpines, dahlias and flowering shrubs were staged by Messrs. J. Cheal and Sons, Messrs. Skelton and Kirby, Messrs. Maxwell and Beale and Messrs. Bunyard and Co.

Messrs. Carter Page and Co., Messrs. R. Tucker and Sons, Messrs. Prichard and Co. of Dorset, Messrs. Bakers, Mr. F. G. Wood, Messrs. Waterer Sons and Crisp, Limited, and Mr. Maurice Prichard all showed alpines.

Besides alpines Messrs. Waterer, Son and Crisp showed Strawberries Royal Sovereign and The Duke, also rhododendrons.

Roses were exhibited by several firms and Messrs. Laxton Bros. showed their



PART OF SIR GEORGE HOLFORD'S WONDERFUL EXHIBIT OF HIPPEASTRUMS.

Digitized by Google

new rose Laxton's Bedford, which is a fragrant crimson hybrid tea.

Messrs. B. Cant, Messrs. F. Cant, the Rev. Pemberton and Messrs. Silvester also showed roses.

Mr. Douglas again showed his fine auriculas and Messrs. Reamsbottom and Co. their St. Brigid anemones.

Daffodils, including many seedlings, were shown by Messrs. Barr and Sons and Messrs. J. R. Pearson and Sons. In addition to daffodils Messrs. Barrs staged Cottage, Darwin and Rembrandt tulips. Besides tulips, Messrs. R. H. Bath staged violas.

Gold-laced polyanthuses and the vivid Muscari Heavenly Blue were exhibited by Mr. G. A. Miller. Messrs. J. A. H. Crook brought some seedling polyanthuses.

Flowering shrubs were shown by Mr. R. C. Notcutt. In Messrs. Russell and Co.'s exhibit Rhododendron fragrantissima was prominent. Azaleas and conifers were exhibited by Messrs. R. and G. Cuthbert.

Kalmia latifolia was conspicuous on Mr. Whitelegg's exhibit, and also some charming seedling Kurume azaleas. It seems a pity, however, that these have been christened. The Japanese raisers are accustomed to name every tiny variety in form and shade and if this plan is to be continued in England, it will only complicate the issue by multiplicity of names.

Sprays of flowering shrubs were to be seen on Mr. Chas. Turner's stand. While Mr. G. Reuthe showed azaleas, rhododendrons and alpines.

Mr. E. H. Watson of Mill Hill had an interesting exhibit of calceolarias, and a pretty little unnamed schizanthus.

From the Mental Hospital, Napsbury, came a bright display of miscellaneous plants. There were such plants as carnations, calceolarias Campanula persicifolia and its white variety, pelargoniums and Saxifraga pyramidalis.

A few hybrid echiums were shown by Lady Rayleigh.

NEW AND RARE PLANTS.

DAPHNE RUPESTRIS GRANDIFLORA.—A small evergreen shrub. It is a fine, well flowered form of a somewhat rare plant. Flowers rich pink. First-class certificate. Shown by Messrs. R. Tucker and Sons.

GEUM REPTANS, KESTON TYPE.—A brilliant little plant with large golden flowers. The foliage appears smaller than we are accustomed to. Award of merit. Shown by Mr. G. Reuthe.

IRIS TURKOMAN.—The general colour effect of this is a rosy purple, but on closer inspection blue tones manifest themselves and the whole flower is iridescent. First-class certificate. Shown by Mr. W. R. Dykes.

CERASUS SERRULATA OJOCHIN.—A blush white form of good substance, very free-flowering. Award of merit. Shown by Mr. R. C. Notcutt.

PRIMULA HYBRIDA LADY THURSBY.—A rich salmon pink form. From our observation it shows no evidence of being a cross. In appearance it looks to be a good pink form of P. pulverulenta. Award of merit. Shown by Mr. G. H. Dalrymple.

PYRUS WISLEY CRAB.—A bright rose form, apparently of very free flowering character. Award of merit. Shown by The Director of R.H.S. Gardens, Wisley.

ORCHIDS

LÆLIO-CATTLEYA IMPERATRIX REGINA. First-class certificate. Shown by Sir George Holford.

The only group of orchids was that staged by Messrs. Stuart Low Company. This contained many odontoglossums, odontiodas, cattleyas, lælio-cattleyas and brasso-cattleyas. Orchids are always a great feature at Chelsea, and no doubt other growers kept their plants back for this forthcoming great Show.

TWO MECONOPSIS

BY R. L. HARROW.

MECONOPSIS latifolia, perhaps more generally known as M. sinciata latifolia, the Kashmir poppy, is deservedly one of the most popular of this genus, and at the same time among the easiest to cultivate. When seen at its best, with stems 2ft. or more in height, bearing numerous flowers of a light Cambridge blue colour which continue to expand over a long period, it is certainly one of the most interesting and admired plants for the rockery or an open position in the wild garden. At Edinburgh, this species reproduces itself naturally and seedlings appear in late autumn in large numbers, often in what might be considered unlikely places, such as in gravel paths. Some strong plants have lately flowered in company with Eryngium prostratum, with a background of Cistus formosus. To secure a good crop of seedlings the ground round about them should not be disturbed, as they apparently germinate best on a firm surface. When sowing the seeds in boxes or pans this should be deferred until early spring, sowing on the surface and scattering a little sand over them, but not sufficient entirely to cover them. A rich soil should be used, in frames or boxes, for pricking the seedlings into when large enough to handle. Transplant the young plants, when nice crowns of leaves are produced, into their permanent positions early enough for them to become established before frosts occur.

THE KASHMIR POPPY, MECONOPSIS LATIFOLIA.

Unlike the Sikkim poppy, this species persists for more than one flowering season, forming thick, fleshy roots an inch or so in diameter, and if a layer of thoroughly rotted manure is placed well beneath the plants when they are planted in their permanent positions a moist subsoil is formed into which these roots delight to penetrate.

Meconopsis simplicifolia Bailey's form is really monocarpic, and a yearly sowing must be made to ensure an annual supply of flowering plants. If this trouble is taken it will amply repay by the beauty of the petals of the flowers, which are borne singly on pedicels about 1ft. to 18ins. in height. They are of the most exquisite blue, especially on the back surface of the petals, the flowers are 2ins. or more across, and a good group is always admired. The foliage and habit suggest the fine yellow relative M. integrifolia in its density, but the foliage shorter and more recurved, with brownish hairs. Colonel Bailey collected this form some years ago on the Tibetan frontiers. The cultivation is very similar to that required by M. latifolia, but the colour is better maintained in a rather more shaded aspect.

NOTES FROM CONTRIBUTORS

THE HERBACEOUS CALCEOLARIA.

THE herbaceous calceolaria is a flower universally beloved. It would be difficult to imagine a flower of greater merit for greenhouse display. The problem of cultivation is not difficult to solve. There are leading principles, of course, and I wish to express them briefly in these notes. The seed may be sown during the last week in May or the first half of June. A cool greenhouse will afford amiable conditions for germination. Seed-pans or boxes should be well drained and filled to within an inch of the rim with a compost consisting of two parts loam, one part leaf-mould and one part sand. The compost should be passed through a ¼in. sieve to give it the requisite degree of fineness. As soon as the seedlings can be safely handled they will benefit by being pricked out into boxes filled with a similar soil mixture. If the seedlings are partially shaded and given cool and moist conditions, they will soon be ready for removal into clean thumb pots. The above compost, with the addition of half a part of partially decayed cow manure, will prove suitable, I believe in rather firm potting, because it induces a sturdy growth. Syringing morning and evening will now help the plants to show healthy progress, and every gardener knows the importance of scrupulous care in watering. Removal into 5in. pots will soon be necessary; it should, by all means, take place before pot-bound conditions obtain. A somewhat richer medium should be used at this stage. Experience has taught me that the following is very satisfactory: Three parts loam, one part leaf-mould, one part of cow manure and one part of sand. When the shock of repotting is over the plants may be transferred to a cold frame with an ash foundation. Each specimen should have the growing point removed while in the frame, to induce a branching habit. When the danger of autumn frosts appears the time has arrived to remove the calceolarias to a shelf in a cool light greenhouse. Here they may remain throughout the winter. Only sufficient water should be given to keep the leaves turgid, and decaying leaves should be removed. The growing weather of March will herald the time of final potting into 7in. or 8in. pots. The compost used at the previous operation will be found suitable if enriched by the addition of a 5in. pot of bone-meal to the barrowful of soil. It is advisable to shade the plants from bright spring sunshine, or the leaves will scorch. When the growths are unable to support themselves, neat bamboo canes may be inserted. I find that herbaceous calceolarias derive much benefit from feeding when their roots reach the final pot sides. Diluted farmyard manure water is the stimulant preferred, and it is given twice a week until colour can be seen in the flowers. There are many strains of this beautiful plant.—GEO. H. COPLEY.

GLADIOLI AT THE SHOWS, 1924.

IT would seem from the schedules of the shows which have reached me that the gladiolus will receive a lift up this summer. In the first schedule (Northampton) in order of date (August 6th) there are two classes for local growers only; but at the Shropshire Society's show (August 20th) there is an open class the prizes for which are £7, £5 and £3, and also a class for cottagers and allotment holders. The floral fête to be held at Southport on August 27th and the two following days should prove to be *the* gladiolus show of the year. Here the gladioli are separated into classes for primulinus only and large-flowered varieties only. The post of honour is given to the Primulinus section, for the first prize is a silver challenge trophy, value £25, and £12, with a second of £10 and a third of £8, the flowers to be arranged for effect on staging in a space 30ft. by 4ft. In another Primulinus class the flowers are to be arranged on staging in a space of 6ft. by 4ft. to show suitability for decorative purposes, the prizes being £3, £2 and £1. This ought to prove an attractive class. Another class (15) is no doubt set for the purpose of showing the garden value of the large-flowered section, as the collection is to be arranged on a ground space of 100 sq. ft., no part to be higher than 7ft. from the ground. Here, again, the prizes are generous, being £10, £6 and £3. The gladiolus may also figure in other classes of both mixed pot and cut flowers, where the prizes are in two cases £20, £15 and £10. There are also classes for the amateur, both for primulinus and large-flowering varieties. Altogether there are seven classes for gladioli alone, the value of the prizes being no less than £67 4s. 6d.

At the Glasgow Show on September 2nd the classes for gladioli have been divided and increased in number. Here also the prizes are on the generous side.

The end of the season will come with the competition for the Foremarke Cup at the Royal Horticultural Society's meeting on September 9th.

As I was about to close this note I received a copy of the schedule of the Canadian Gladiolus Society's third annual exhibition, to be held on August 20th and 21st. It contains over 140 classes!—SMILAX.

CORRESPONDENCE

THE PROPAGATION OF CHOISYA TERNATA.

YOUR correspondent, Mr. H. Stewart Wacher (see page 309), has experienced what has occurred to many when attempting to propagate Choisya ternata and other fleshy evergreen shrubs; the more remarkable thing is that such cuttings do not always behave in this way even when they are expected to do so.

I have on several occasions had Choisya ternata and also skimmias remain perfectly fresh and green for over two years, but, as my patience or the need of the pots for something else could not hold out for a longer period, I am not able to answer the question of how long the cuttings will remain alive in that unrooted state. Sometimes, when the callus is injured either in the process of turning the pot out for examination or by deliberately doing so with a knife, roots may be induced to form by a second attempt by the callus.

From experience, I am inclined to think that the reason for this remarkable behaviour of some types of cuttings is partly due to (*a*) the time of year and condition of growth, and (*b*) the type of cutting selected. If the cuttings are taken early in the growing season, such as in May, the wood is scarcely developed enough to form a set of roots, although it may have enough energy to form a callus; this callus in time gets hard and is unable to send out roots at a later period. Growth of the types of shrubs under notice is comparatively slow, and therefore the cuttings cannot be treated as a soft-wooded growth—such as fuchsias, for example—unless, of course, some special method, such as a plunging bed in a propagating case, is employed. If the cuttings are carefully selected so as to be only 3ins. long and slipped out with a heel—which, by the way, need not be dressed with a knife—there is a smaller and more natural wound to be healed, and the energy of the cutting can be given almost entirely to root formation instead of a large callus. If the cuttings are taken later in the season, and carefully selected, rooting may be surprisingly rapid, as it may, in other circumstances, be remarkably slow. This I have proved in the case of Choisya ternata.

Last July we had cuttings of skimmias given us; fairly large branches were sent, but by good luck these were terminated by a bunch of small shoots, generally three or four arising from about the same level at the terminal point. These shoots were merely stripped off, no other preparation given, and the cuttings inserted in ordinary soil in 5in. pots; the latter afterwards were plunged in the soil of a cold frame along with other cuttings. In March, these cuttings, well rooted, were planted out in the nursery and are growing well.

Similar treatment was given to the common and small-leaved types of myrtle with equally good results. We had similar good fortune with the Choisya two years ago.

There is a great deal of pleasure and satisfaction to be derived from propagating one's own shrubs and all good gardeners soon learn the way to solicit the offer of cuttings from a neighbour. As a general tip to amateur propagators, the best time to take cuttings of shrubs is when they are offered you, but ask to be allowed to select the cuttings yourself. Select short sturdy shoots which can be inserted without too much use of the knife. If a heel can be obtained, so much the better. Such cuttings can generally be found low down, at the back or even in the centre of the bush. Vigorous growing tips should be avoided, if possible.

I have seen cottagers root cuttings of the lemon-scented verbena (aloysia) as easily as one would pentstemons, by merely sticking them in their garden; while I have also seen noted gardeners driven almost to desperation in their attempts to produce the same result. It is probably all a matter of selection of the cuttings, although both parties may not be aware of that.—A. D. TURNER, *Bridgwater, Somerset*.

THE EARLY-FLOWERING CHRYSANTHEMUMS

I READ with interest the article on early-flowering chrysanthemums by your able correspondent, Mr. Norman Lambert, and trust that the remarks made by him will widen the interest in these deservedly popular flowers. I find that articles such as that referred to do a lot of good by reason of the fact that they draw the attention of the gardening public to the newer and better varieties. I must confess to disappointment at finding that Mr. Lambert only makes a short reference to singles. During the last few years this nursery and many others have raised many splendid varieties, and I am confident that they have only to be more widely known to have the appreciation they deserve. They certainly are unsurpassed f-

Digitized by Google

table decoration and suffer much less in a rainy season. They can be had in a great variety of colours and do not need disbudding. —A. S. (*Sydenham's Gayborder Nursery*).

PLANTS WITH LEGENDS.

ALTHOUGH it is rather late in the day, I should like to call the attention of that lady who was planting a garden of legendary flowers, and who asked for advice in the columns of THE GARDEN, to the books written by the Rev. H. Friend, "Flowers and Flower-lore"; Elizabeth Haig, "Floral Symbolism of the Great Masters"; T. F. Thiselton-Dyer, "Folklore of Plants"; and the various books mentioned in the bibliographies therein. Very little has escaped these authors. I am interested in the same way myself, and will be glad if anyone can tell me whether "Paris daisies" were sold in Italy in honour of Queen Margarita, as roses are on Alexandra Day, and, if so, for what purpose? I understand that Alexandra Day was patterned after the Italian *fête* on St. Margharita's Day. I am also curious to know whether the Prime Minister's house, Chequers, was named after mountain ashes growing there? I believe that is one name for the rowan.

I am enclosing some photographs of American shrubs of the littoral which may interest those seeking for something which will stand sea air and drought. One is the beach plum (Prunus maritima), which grows in thickets in arid soil near the Atlantic, spreading itself in low domes most exquisitely adorned in early spring, with countless small snowy blossoms on dark twigs, nearly leafless. In late summer the branches are equally crowded with green and purple small fruit, too thin-fleshed and puckery for eating raw, but very satisfactory for jam. Transplanted into good soil, this beach plum is apt to become a sizeable and shapely tree.

Grouped with the beach plums are the bayberries (Myrica) and groundsel-shrubs. The former are rather massive in effect: rounded clusters of heavy, dark-coloured, aromatic foliage, frequented by orange-and-black myrtle warblers when the fruit is ripe. This fruit consists of myriads of tiny, hard, wrinkled nutlets thickly covered with white wax, clinging to the bases of twig and branch. These bayberries were of economic importance to the early settlers. Jesuits and colonists boiled the fruit by the bushel to get the "tallow," which they made into candles, deliciously fragrant at the moment of their expiring. Laws had to be made to prevent gathering them before they were ripe. The twigs studded with waxy fruits are charming for a winter bouquet, and permanent. The groundsel-shrub rather likes swampy shores. It is Baccharis halimifolia, a composite, throwing up tall stems in a group, plentifully furnished with fleshy, deeply toothed leaves richly green against the yellow sands. It is not very conspicuous until autumn, when every stem is topped by huge paniculate heads, forming pyramids of gleaming white tufts of pappus.

Since writing the above I have been grieved by the very cursory treatment awarded our national fruit, or vegetable, or bread-stuff, whichever you like, which the erudite call maize, but which in America is known simply as "corn." Ruth amid the golden corn is visualised by American youth as a flapper wandering through autumnal fields of rustling, ripening maize with huge stalks towering above her head.

Some wit cruelly said of the early English colonists in New England that—

"First they fell upon their knees
And then upon the aborigines."

However that may have been, they certainly pounced upon the Indian's corn, as they promptly dubbed the golden kernels which the pitying red men offered, sometimes involuntarily, since the half-starved adventurers gathered up the stores hidden in caches wherever they could find them. The Plymouth folk, at least, paid for the corn. They used much of it for seed, being shown by the Indians how to plant, manure with fish, and cultivate this most important crop, which saved these reckless innocents.

Most of the Eastern tribes halted long enough in their nomadic life roughly to clear ground and scratch it with their rude implements so that they could plant the "three sisters," corn, squash and beans. With a delightful economy of labour they made one shallow hole and deposited therein a rotting fish, on top of which were dropped the seeds of the above. The corn would shoot up, carrying the bean-vine, and the squash would scramble about in the warm shade of the heavily foliaged stalks, and all would grow obligingly among the stumps, with but little attention.

To this day we are apt to put in corn as a first hoed crop among the stumps of newly cleared land, and still plant squash and pumpkins in the little mounds around the corn, the golden fruit being disclosed when the corn is shocked. The earth must be banked around the shallowly rooted stalks, for roots spring out at the surface, and besides, one has to brace the stalk against the wind. It is not at all unusual to go out after a squall and find one's entire cornfield lying down in windrows. In the garden one props up the top-heavy stalks; but in the field it somehow rights itself.

But there is corn and corn—a circumstance which your correspondent has overlooked. There is fodder corn, grown in rows to be

MYRICA CERIFERA. THE FRUIT IS COATED WITH WAX.

THE BEACH PLUM. PRUNUS MARITIMA.

cut green for cattle while young and succulent; and there is the field corn of gigantic stature, grown only for the ripened kernels, carried in enormous ears (we do not call them cobs, reserving that term for the hard cylinder on which they sit). When frost nears, these stalks will be cut and leaned together in shocks, ears and all, leaving exposed the golden pumpkins and squash that have been growing in the moist heat and shade below the corn. Later in the autumn, all available men gather about these shocks and devote themselves to ridding the ears—crowded to the tips with the hard, plump, golden kernels—of their withered husks. This is the modern "corn-husking," but there are no more of the cheerful neighbourhood "bees" when man and maid pitched in and turned the laborious and hand-rasping work into a frolic.

"The laws of husking every wight can tell,
And sure no laws he ever keeps so well,
For each red ear a gen'ral kiss he gains,
With each smut ear she smuts the luckless swains,
But when to some sweet maid a prize is cast,
Red as her lips and taper as her waist,
She walks around, and culls one favored beau,
Who leaps, the luscious tribute to bestow."

Later, the huge ears are stripped of their kernels by a corn-shelling machine, for poultry, cattle, and for human food.

Now we come to the vegetable "corn on the cob." Presumably, immature field corn, baked in ashes while still in its enwrapping husks, was first used; but as time has gone on, more and more tenderness and sweetness have been demanded, so that there are all kinds of "sweet corn" on the market, early and late, tall and short, and these are the only varieties to be chosen if one wants a satisfactory edible. The seed of these is translucent, wrinkled and generally pale, although a favourite dwarf, Golden Bantam, is yellow, and my pet variety, Black Mexican, which I suspect to have originated in the *pueblos* of the West, where the Indians were great fanciers of maize, is purple-black when mature. The dwarf varieties are often grown in rows, as your correspondent suggests, but the larger ones are usually planted in hills of from five to seven stalks—a reminiscence of the Indian. These stalks bear quickly. It is a ticklish job to pluck the corn at the exact stage when it is most delicious. We first examine the "tassel." If the silk is rusty brown and withering, it is worth looking into, and we cautiously tear down the husk a bit. Alas! half of the ear is still too small—the kernels are not filled out and the silk is bright green among them; the next shows threads of bright sienna silk all the way down and the kernels are tough to the nail—too old; the next is just right, all kernels filled out, milky juice flowing from the cut kernel, the silk still pale and fresh.

Then comes the cooking. There must be plenty of water and boiling hard, so that after husking and silking the pretty ears we can drop them in to dance around for ten minutes, with a dash of salt. Then they are whisked out and buried in a napkin, and served as quickly as possible. Ultra-refinement has tried to introduce machinery for holding the hot ear without touching it with the fingers, but the ordinary creature reverts to savagery and, spreading the rows with butter and salt, grasps the ear by its end boldly, and proceeds to gnaw down its length, squirrel fashion, as gracefully as he may.

There is material for a book on the treatment of corn by the Indians, from its planting to its harvesting, and onward through its culinary preparation. Countless ceremonies were evolved for its protection and for the encouragement of the crop, and for the propitiation of their gods in reference to it, and there are many stories of its origin; but this would probably interest but few—HELEN INGERSOLL, *East Setauket, New York.*

GENTIANA VERNA.

IN reference to "Formakin's" notes on this species (p. 309), suggesting that it is possibly only a short-lived plant, it may be of interest to know of two plants that have been in my garden for fourteen years or so. Originally part of half a dozen received from the Emerald Isle, and owing partly to the rough and ready way they are sent out and also to my being just a beginner, most of them went the usual way. However, the two plants referred to were in sufficiently good condition to be moved on to an island moraine that I had constructed in 1913. They have flourished and flowered there annually ever since. In 1917 the two plants had over seventy flowers, foliage and flowers being large enough for G. angulosa, which probably is only G. verna in richer soil and better conditions, such as plants seem to luxuriate in near Mont Cenis. In 1922 the plants had only about thirty flowers, and in 1923 the same. Owing to the moraine bed, which is about 3ft. 6ins. deep, not having been properly consolidated, some subsidence took place where the plants were situated, involving remaking, and in doing this the thread-like roots of the gentians, which I found about 3ft. long and partially suspended, were considerably interfered with, and the reduction in the size of the plants and number of flowers is no doubt due to this. This year the two plants only have twenty flowers, but this is probably due to the very dry April and May of 1923, which evidently checked the setting of the flowers. The plant is very healthy, with large flowers just opening out, fully a month later than last year. Another plant in somewhat similar conditions, which had seventeen flowers on last year, has only nine this year.

G. verna usually ripens seeds with me if allowed, but I make a practice of cutting the dead flowers off so as to strengthen the plant, and this probably ensures more flowers. I have a good number of seedlings from my own seeds at present, which I am putting out in groups instead of single plants, which are very fragile and slow-growing.

Plants in a wild state growing in grass usually seem to have very few flowers to a plant, and, so far as my observations go, the finer flowered plants are those that are more or less isolated from the grass. I have seen odd plants or plant groups in a very small area with probably twenty flowers, but this is a much more rare occurrence in Nature, where the plant has to compete for its existence.—T. ASHTON LOFTHOUSE, *Middlesbrough.*

THE MIDLAND DAFFODIL SHOW.

IN my report of the above-named show (page 323), all the daffodils appearing under the heading "New Daffodils" received awards.—JOSEPH JACOB.

LYSICHITUM CAMTSCHATCENSE.

ON page 347, and again on pages 374 and 468 of THE GARDEN, 1922, are various references to this plant. The first of those notes concerned some I had recently received from Vancouver. They grew at Milnes Landing, near Victoria. These same plants have now commenced to flower. They appear to do quite well in an ordinary border without any shade or protection on rather high ground in this Sussex garden. I suggest, however, that the place where they are planted be slightly sunk below the surrounding level with a good depth (I think from 18ins. to 2ft.) of leaf-mould and well decayed leaves and bits of decayed wood around them, mixed with rich garden soil, where the roots may have access to constant moisture at that depth. The recent rains have, no doubt, helped them considerably in a position that is far removed from what one would suppose to be most congenial to them. For the first two seasons they did nothing but throw up a few small leaves, and I was thinking of moving them to the edge of a pond, but during the last few weeks they have made great strides. Now one or two of the leaves look as if they will grow to the size of a dinner-plate. They are of a beautiful healthy green, closely resembling those of a colewort. I send you a small bloom, as I am leaving the largest one for seed. The latter is nearly half as large again as the one sent.—EDWARD SHOOSMITH.

[Even this bloom was excellent.—ED.]

ANSWERS TO CORRESPONDENTS

TREES AND SHRUBS.

Lichen on Azaleas (R. D.).—The moss and lichens on hardy azaleas can be destroyed by spraying the bushes during the winter with a caustic wash. This may be made by taking 2lb. of caustic soda (98 per cent.), half a pound of soft soap, five pints of paraffin and ten gallons of soft water, mixing them as follows: Dissolve the soft soap in one gallon of boiling water, and while hot add the paraffin and stir into a creamy liquid. Dissolve the caustic soda in nine gallons of soft water, and into the solution pour the paraffin emulsion and stir thoroughly. The mixture may only be used when the bushes are dormant, as the soda will burn expanding buds and leaves. India-rubber or leather gloves should be worn while the wash is being applied, and a calm day should be selected for the work.

FRUIT GARDEN.

Pear Trees and Insect Pests (L. P.).—Many pests attack pear trees. Caterpillars of winter moth, March moth and other lepidoptera, and grubs of pear and cherry sawfly and other sawflies, and weevils of several kinds all bite foliage, the pear midge grubs feed in the fruits and the leaf-curling midge in the rolled leaves; aphides of two or three species and occasionally capsid bugs attack the tree; the larvæ of the wood leopard moth burrow into the wood. Canker sometimes attacks the branches, pear scab the leaves, shoots and fruits, one or two other fungi the foliage, and the pear mite burrows into and blisters the leaves. All these need dealing with in their own special way, and unless they are recognised before attempts are made to deal with them waste may easily arise. It would be better to send us specimens of the pests met with for identification and advice as they arise.

MISCELLANEOUS.

Raising Seedlings under Cloches (C. E. O.).—Until the seedlings appear it is not necessary to ventilate the cloches, but rather to shade them during the warmest part of the day. As soon as the seedlings are above the ground, air must be admitted on warm days. This is done by tilting the glasses on one side, raising them about an inch by placing a stone under them. Remove the stone about three or four o'clock in the afternoon. It is not necessary to ventilate on cold, dull days. The cloches must be taken off while watering the seeds or seedlings.

Names of Plants.—(H. B.).—1, Primula farinosa; 2, P. Juliæ; 3, Saxifraga bathonensis; 4, Veronica filiformis; 5, Phlox lilacina; 6, Lamium maculatum.——(J. A. E.)—1, Helleborus orientalis; 2, Daphne Laureola.

BOOK REVIEW

A New Book on Irises.—When Mr. Dykes gave us "The Genus Iris" some years ago we realised that he had done rather more than publish the most complete and authoritative work on the iris. He had, in fact, produced what was, in many respects, the finest monograph on any genus hitherto published in the English language. A small popular work that preceded it soon went out of print and is now unobtainable, except an occasional copy, at a premium, from second-hand booksellers.

The present work, "A Handbook of Garden Irises," by W. R. Dykes, M.A., L-ès-L., Secretary of the Royal Horticultural Society (published by Martin Hopkinson and Co., Limited, price 12s. 6d. net), is something between those two, being less ambitious than the greater and dealing much more fully with the subject than the smaller. Every iris lover, and most gardeners, will be with me when I disagree with the author on one point, and that is the opening remark of his preface. "Some apology is needed for the production of a third book on irises." No apology will ever be necessary when Mr. Dykes has anything to write or say on this subject. Primarily this is due to the fact that his every word is penned from an experience gained at first hand, and from his own personal and intimate knowledge of the things he writes of. Hearsay, or the theories of others carry little weight with him, and when he quotes them it is either to substantiate them, and give us his reason for so doing, or to disagree with them, and prove his case where possible. If it is not possible he states the pros and cons and leaves it to time to decide, or the reader to form his own conclusions. Thus, he "speaks as one having authority," and no one will have the temerity to doubt his pre-eminent ability to do so, or that he of all living men has the most complete knowledge of the genus, both from the scientific, and also the cultural sides. For this reason it is devoutly to be hoped that at no distant date means may be found to place under his control a really representative and in a sense "national" collection of the irises of the world. This is by the way, but it will interest iris lovers to know that such an effort is to be made, and to assist in its consummation every garden lover can help by joining the Iris Society of England which has now opened its membership to all interested.

The book contains some 250 pages of well and clearly printed matter, and a careful perusal fails to find a single paragraph that one could wish omitted, indeed, there is not a line of "padding" between the two covers. Every section of the genus is discussed and although from the purely gardening point of view, some sections may appear to have received an undue proportion of attention, in comparison with that bestowed on others that are, and always will be, more popular as garden plants, this is perfectly excusable, denoting as it does the author's personal preferences. After all Mr. Dykes is essentially a "species" gardener, and one often suspects him of having at least as much of the collector as gardener in his composition. Nevertheless the peculiarities of every section are lucidly explained, often in the most minute detail. The table at the end of the book, giving names of species, heights, time of flowering, and the best time to plant each is invaluable. Every chapter is crammed with information, useful, not only to the ordinary gardener, but also to those whose acquaintance with irises generally has, by experience, become more advanced. In fact, the garden lover who wants the most reliable and concise information obtainable cannot afford to be without this book, and it will meet more of his requirements than any other work on the subject.

It belongs essentially to that class of book that is practical rather than poetic, technical than pictorial. Even the illustrations conform to this description. Every plate is a careful drawing which emphasises the principal characteristics of the species it portrays, and for this purpose drawings are often much more explicit than photographs. It is within the power of the delineator to bring out salient features in a way that photography sometimes fails to achieve. True, such illustrations are analytical rather than beautiful, botanical than horticultural, and the interest in them lies in the fact that they tell us more of what things are than what they will do for us in the garden. This indeed is characteristic of the whole book, perhaps a little also of its writer.

On his magic carpet Mr. Dykes sweeps us across continents and drops us down here and there, selects a species, and pulls it apart, almost with the ruthlessness of a boy stripping the legs and wings from a fly. Then, having told us all that is known of it, even to such details as "the ripe seeds rattle when the capsules of I. xiphioides are shaken. This is impossible in the narrower capsules of I. Xiphium," and, before we have had time to apply his theories regarding the identification of the sequence of origin of certain sections by their seeds, he whisks us off a few thousands of miles to repeat the operation on another species. But his information extends further than this, for he not only tells us what they are, but how, and where we can grow them, and how to increase them. Such information as the following is decisive and valuable. After pointing out that I. lævigata and I. Kæmpferi are quite distinct species, he says, "I. lævigata is a true bog plant, and will flourish where it is wet all through the year. I. Kæmpferi on the other hand is not really a bog plant, and should be kept comparatively dry except when growth is active," a statement by the way that has been fully borne out by experience; but I think he intends the "comparatively" in this case to mean exactly what he says, and to apply as between these two species, and not as between I. Kæmpferi and other sections of the genus. He would not advise, for instance, that I. Kæmpferi will stand the dry conditions that can be applied to the bearded section generally.

As I have already said, and despite Mr. Dyke's assurance that the book is "intended for gardeners," it is still rather botanical than horticultural. This in no sense detracts from its value, but there are two distinct types among the garden lovers of to-day. The one is interested in the plant for what it is, and conceives no more desirable achievement than its successful cultivation. To this class the book will prove ideal. The other section (by far the larger one, too), regards the plant rather from the standpoint of what it will do in the general garden scheme, and to this class the book may prove slightly disappointing. The author's knowledge of the genus is so intimate and vast, that one is inclined to suspect that he rather loses sight of the æsthetic value for garden picture making of the plants he describes. Under his cold, scientific analyses the frail beauties of the plant sometimes disappear. Where the plants come from, what they are, and how to grow them, is not quite enough for the great multitude of gardeners (of both sexes) of to-day. There is abroad the ardent desire "to so use our plants that they shall form beautiful pictures in our gardens." Much of this may be the result of feminine influence on which has been particularly strong in gardening. Combinations of form and colour, the gratification of that sense of composition that makes for true art in the garden, as elsewhere, is the keynote of the development of beauty. The disposition of plants in such a way that they shall borrow from their surroundings some harmony of association, and lend to their environments their own individual charms is the laudable desire of every true gardener. In this Mr. Dykes does not help us much. In this he does himself less than justice. He is too good and true a gardener for it to be said of him that "his botany is all names, not powers. poets and romancers talk of herbs of grace and healing, but what does the botanist know of the virtues of his weeds?" Perhaps some day he will give us a book in which he will tell us of the exquisite beauty of the plants and their potentialities for garden picture making, rather than of their bones, sinews, muscles, blood and intestines.

The book is such a perfect example of its kind that adverse criticism would be absurd and impossible, but it does just leave an impression of a music lover sitting among the dismembered components of a magnificent organ, revelling in the perfection of the individual parts, and in so doing forgetting its soul of music, and the power of those parts in unison.

In all his varied experience he must have come across innumerable pictures that thrilled him, not so much because of what they were, as where they were, and with what conditions of beauty they were associated: some happy combination of circumstances that made the plants themselves more beautiful. For the moment he forgot to split his butterfly's wing to see if the colour went right through. If he would tell us of such circumstances, even if he confined his remarks to the species he loves so much, he would do a great deal towards realising his own desire, "that attempts will be made to get into cultivation more of the wild forms and species" than anything or anyone else could possibly do.—GEO. DILLISTONE.

The Horticultural Club.—The Club has decided to contribute towards the entertaining of the members of the Federation Horticole Professionnelle Internationale who are meeting for their annual conference on May 28th and 29th. The entertaining will be done in conjunction with the Chamber of Horticulture, the Horticultural Trades' Association and the British Florists' Federation and is to take the form of a luncheon on Thursday, May 29th, also a dinner on the same evening, followed by a cabaret show. Donations are invited from members of this club to the Entertainment Fund and may be sent either to the Treasurer, Mr. Peter R. Barr, 11, King Street, Covent Garden, W.C.2, or to the Hon. Secretary, G. F. Tinley, 855, London Road, Westcliff-on-Sea, Essex. It is not expected that members who are contributing through the other organisations mentioned will contribute through the Club, unless they desire to do so.

FORTHCOMING EVENTS.

May 24.—Wakefield Tulip Society's Exhibition (four days).

May 27.—Royal Horticultural Society's Great Spring Show at Chelsea (three days).—Bath and West and Southern Counties Society's Exhibition (five days).

May 28.—Annual General Meeting of the Kew Guild, to be held at the Imperial Hotel, Russell Square, London, W.C.1, at 6 p.m. The Annual Dinner will take place after the Meeting at 7.15 p.m.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

VEGETABLES UNDER GLASS.

Tomatoes.—With more congenial weather these are making considerable progress, and ripe fruit may be soon gathered from the early plants. No fire heat is needed and plenty of ventilation may be allowed. Later batches are growing freely, and whether they are planted out on the stages or in large pots, the roots should be fed with liquid manure or some reliable fertiliser when the first truss of blossom is set. Never allow the plants to become really dry, and continue to tie the main growth to the supports, at the same time removing all the side shoots. The plants intended for putting out in the open should be hardened off by placing them in a cold frame, drawing off the lights during the day and eventually at night. Select a sheltered sunny position and set them out about 2ft. apart. White fly will, no doubt, make its appearance in the houses, and only consistent warfare will hold it in check. A white fly fumigant should be used before this pest has made much headway. Spraying the plants, especially the undersides of the leaves, with an insecticide is also beneficial, but not when the fruit is ripening. A non-poisonous insecticide is recommended.

THE HARDY FRUIT GARDEN.

Gooseberries.—Where the bushes have not been ruined by birds, a fairly good crop of fruit is assured, and if the ground did not receive a dressing of manure in the autumn, it is a good plan to give them a sprinkling of Thomson's manure at this period, choosing showery weather if possible. A dusting of soot is also recommended. Where the bushes are producing a heavy crop, the thinning of the fruits should begin as soon as possible. Birds have played havoc with fruit buds this season.

General Work.—Keep down weeds by using the hoe freely. Insect pests are liable to be troublesome and should be dealt with early, while disbudding and tying of wall trees will require attention.

THE FLOWER GARDEN.

Summer Bedding Plants.—The time has arrived for making preparations for summer bedding, and now such plants as pelargoniums, begonias, heliotrope, etc., should be in cold frames and fully exposed when the weather is favourable. In the meantime such plants as violas, pansies, verbenas, pentstemons, calceolarias, stocks, asters, Phlox Drummondii and antirrhinums may be planted where they are intended to flower. Beds that have been filled with wallflowers may be dug over, at the same time incorporating a small quantity of decayed manure. See that pot plants are well soaked with water before they are placed in the beds, and for a week or two it will be necessary to keep the soil in a moist condition until the roots are established.

Annuals.—These are now large enough for thinning, and in many gardens these plants are spoilt because of overcrowding. Blank spaces may be filled by transplanting, and it will be advisable to keep the plants well supplied with water.

Roses.—A watch should be kept for the grub that gets between the leaves and destroys the flower bud. Pick off all affected leaves and burn them. Weeds and suckers should be held in check by periodical hoeings. Greenfly may be present and will become troublesome unless the bushes are sprayed before this pest has made much headway.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Brassicas.—We have now approached what might be termed the great planting-out time, and so, within the next fortnight, garden ground should be studded with sturdy vegetable plants. All vegetables which are to be in use in autumn and throughout the winter and spring should be planted now, such as borecole, broccoli, Brussels sprouts, cabbages, cauliflowers and savoys in their several varieties.

Peas.—Although sowings are sometimes made later than the end of this month, it is not always advisable to do so except in favoured localities. When sowing late it is usual to put in a quick-maturing or early variety, such as The Pilot. We have sown the early variety Essex Star on June 8th and had pods for pulling by the middle of September.

Root Crops.—Thinning the young plants of beetroots, carrots and parsnips, etc., will now call for attention. Where the two last named crops are growing in prepared holes, care should be taken by the worker to leave not only the best plants but the best placed ones—that is, those occupying the centre of the holes. Every precaution should be taken when thinning the carrots to leave none of the roots lying about, as it is said that even the aroma in the air around, caused by the thinning, will attract the carrot fly. Each carrot left should have the soil brought up and around the top, then pressed fairly firm with the fingers, so that nothing of the tender root is left exposed. Every evening after thinning spray the plants with Abol or Clensel—either insecticide, of course, being well mixed with water. The smell from the insecticide is to counteract the aroma from the carrots, and so ward off the fly. In fact, it is safer to give a gentle spray once a week for the next five or six weeks.

THE FLOWER GARDEN.

Tender Plants.—It is rather risky to start bedding out such plants as ageratum, begonias and heliotrope, as they are so easily spoiled by frosts—and we are still liable to get a little frost at times. It is better, therefore, to leave all tender bedding plants where protection of some kind can be given at nights, at least for another week.

FRUITS UNDER GLASS.

Melons.—Now that bedding plants, etc., have been cleared from the houses, more room will be available indoors. Melons which have been forwarded in 6in. pots, should be planted. Once the plants are fairly established in the beds a little lime should be sprinkled on the soil around each stem. No water should be allowed to reach the stems at the soil surface; hence the practice of making little mounds in which to plant the melons, as watering can then be done in the spaces between. Due attention should be given to pollinating the female flowers as they expand.

Peaches.—Trees bearing heavy crops in late houses should be gone over and further thinnings made. Continue to syringe the trees twice daily to keep the foliage free from insect pests. These peaches, grown under more airy and natural conditions, should produce better flavoured and more highly coloured fruit.

Vines.—The principal work among the late grapes, such as Alicante, Lady Downe's, Mrs. Pince and Risin de Calabre, will be thinning—in some cases for the second time—among the bunches. Alicante is a very free setting variety.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Brunfelsias (syn. Francisea).—Although generally regarded as stove plants, these beautiful plants in common with many others that require a fairly high temperature when making their growth, stand quite well in an ordinary greenhouse when they are in flower. These plants have the merit of producing a succession of flowers over a long period, but are generally at their best during May and June. They are easily propagated during the summer months by means of half ripened shoots inserted in pots of sandy soil, and plunged in a close case with slight bottom heat. During their growing season they enjoy a moist atmosphere, and a temperature of about 60°. When growth is completed they will stand in a lower temperature, and during the winter should be kept drier at the root, as they lose most of their foliage. They grow quite freely in a compost consisting of a good medium loam, with the addition of a little fibrous peat, leaf-soil and sand. The species and varieties most common in cultivation are B. americana, a fragrant species, the flowers of which open creamy white, and then change to yellow; B. calycina, very free flowering, as also is its fine variety known as macrantha. The latter is the largest-flowered variety, and its large, deep bluish-purple flowers are produced in great profusion; small plants rooted last summer are now flowering freely in sixty sized pots. B. eximia is also generally grown, and this fine plant is probably also a variety of B. calycina.

Browallia viscosa is useful for the conservatory and greenhouse, as by means of successional sowing it may be had in flower for at least nine months. This species may be flowered in 48-sized pots, but it is a strong grower and better results are obtained if it is potted on into 6in. pots, stopping the young plants several times to form a good bushy habit. It grows freely in any good potting compost and only requires ordinary cool house treatment. B. speciosa major is the largest-flowered kind and requires an intermediate temperature in its younger stages, but stands quite well in the greenhouse when in flower. It is by no means such an easy plant as B. viscosa; it requires careful watering and must not be over potted. There is a white-flowered variety, but it is not such a strong grower as the type; both can be propagated by means of cuttings, but seedlings give the best results.

Alonsoa Warscewiczii is a very beautiful half-hardy annual, with scarlet flowers, which is very suitable for pot culture. Plants from seed sown early in the year flower towards the end of May. If sown about the beginning of July the subsequent plants prove useful for flowering during the autumn. A. gracilis has also got scarlet flowers, while A. Mutisii has pink flowers with crimson centres. They all grow about 12ins. high and succeed in a cool house under the conditions usually given half-hardy annuals grown for pot work. A. incisifolia is a perennial species which is worthy of more general cultivation. It is an elegant plant with bright red flowers, and by growing several batches may be had in flower over a long period. Cuttings root readily at any time in a close case. If the young plants are pinched several times they soon make nice bushy plants in 48-sized pots. If larger specimens are required they should be potted on into 6in. pots. This plant only requires cool greenhouse treatment during all stages of its cultivation.

THE CHELSEA SHOW

WHAT am I to say about the Chelsea Show that has not been said many times before and many times better said? In a sentimental vein I could talk upon every Englishman's inherited love of flowers or in a patriotic strain say that this is the culminating peak of the gardeners' year which proves conclusively that we are at least superior to all other nations in horticulture, but this might be slightly tinged with sarcasm. Behind it all would be a vague wonder as to what was the real spirit of Chelsea, which is as elusive as a will o' the wisp and as difficult of definition as the Fifth Dimension.

Let us discuss for a moment the different classes which throng the gardens on Show days. At the one end of the scale is a devoted multitude to whom Chelsea is a Mecca. It may be their only visit to London in the year; they examine everything with a stern thoroughness as if it was a task to be accomplished and to be accomplished to the top of their bent. They know what they are talking about and are not carried away by the excitement of the moment. They purchase not only with an eye to their pocket, but with discrimination, for they can see the merits and demerits of a plant and know their own capacity for cultivation. That is the class, luckily a large one, which is surely the backbone of Chelsea Show; they are liked and trusted by the nurserymen, to whom Chelsea means bread and butter. Knowing their own limitations, they buy cautiously, and do not turn around in six months' time and complain that the plants supplied were hopeless. They do not go into raptures, which may or may not be sincere, but very little escapes them.

I have enlarged upon the merits of this class, for they deserve every morsel of praise. At the other end is another class, unfortunately almost as large, who play at gardening because they think it is correct to do so. Some of them are women and some are men. They wander through the tents and gardens with no particular object in view. They are full of adulation; "How charming!" and "Isn't that simply marvellous?" are heard on every side. They order a dozen plants without taking the trouble to find out if it is suitable for their requirements; it may come from the Sahara or from Greenland for all they care. They are the butterflies of gardening. Between the two classes come the rest, those who are not quite sure of themselves, but who have somewhere in the background that instinctive love of flowers which *is* our birthright. Perhaps it is for them that the Chelsea Show exists—or, rather, perhaps it is they who make it such a success. Their ideas may be nebulous to begin with, but slowly they crystallise and in a twinkling they may become the most expert of gardeners.

To return to the Show, surely there is no trade in the world which is so lucky in having such tempting wares to set before the purchaser: colour, texture, beauty of form, rarity, shape, they may all be present in the one plant, so what more can one want. This brings to mind the one criticism that can be made of the Chelsea Show, that it is so much of a selling medium and so little of a competition. Amateurs are swamped by the number of trade exhibits, and yet it is perhaps just as well, for 90 per cent. of those who visit Chelsea do so in order to buy either on the spot or in the future.

In our forecast last week we gave a few general notes about many of the main exhibits, and we hope that they were of some assistance to our readers. In this number will be found the first portion of our full report, which will be concluded in our next issue. These are facts which must be duly chronicled. Somebody has suggested that we should publish a map showing the position of the different exhibitors. To begin with, the idea sounded enticing, but then a picture came before me of hundreds of our readers moving along with the crowd inside the tents. Dozens of GARDENS would be opened and elbows thrust out in consequence. Our devoted readers would trip over boxes and collide with stands in their efforts to steer a course by means of our map—so the idea was dropped. The best method is to decide to see everything and drift with the throng. The colours will be kaleidoscopic, and the result will be that you retire at the end tired and footsore, but you will have the satisfaction that it was in a good cause and that you have seen everything. I am as far away as ever from finding out the spirit which draws everyone to the Chelsea Show. Perhaps it is a fetish; if so, it is a benign one.

E. H. M. C.

The Hon. Vicary Gibbs has again kindly consented to the opening to the public of the gardens of Aldenham House on the Saturdays of July, August and September, and the August Bank Holiday Monday, on the same conditions as in previous years, viz., that children must be accompanied by a grown-up person, and that dogs will not be permitted. These facilities will not be available on Saturday, July 19th, as this is the date of the annual floral fête of the Elstree and District Horticultural Society at Aldenham Park, when admission is only possible on payment of the Society's entrance fees.

Dame Alice Godman has announced that South Lodge, Horsham, is open to the public on Thursday, May 29th, and Saturday, May 31st. The entrance money of 1s. per person is to be given to the Sussex Hospitals.

AN IGNORAMUS AT KEW

BY BERNARD DARWIN.

I AM as ignorant and unbotanical a person as exists in the whole world. I can apply to myself the remark made by my great-uncle Ras to his brother Charles, "My dear fellow, I don't care a damn for the whole kingdom of Nature." I have, however, this one redeeming quality, that I like going to Kew.

When I go there I always experience the same series of emotions. First of all, I feel a certain transient shame at my ignorance of the beautiful things there. Next there comes a certain hostility to science which I cannot altogether smother. It is for a moment rather annoying to have an oak, which I really do know by sight, labelled "Quercus pedunculata"; there seems something "highbrow" about it. Then both these emotions are swallowed up in an enjoyment of the peacefulness and the spaciousness of Kew. Kew is so big that there is never a crowd. I have actually eaten my lunch out of doors there on a Bank Holiday. It sounds sheer madness, yet we ate our sandwiches in the perfect solitude of a most enchanting thicket. And as to peacefulness, Kew can in about a quarter of an hour make a complete loafer out of the most restless being. I can look out on the Old Deer Park, where I often play golf, and watch the golfers with pity and amazement, wondering why, when they might sit still and look at bluebells, they pursue a ball with such ungraceful and ineffective antics.

As I always feel these same emotions, so also I have a certain procedure at Kew from which I scarcely deviate. I followed it once more the other day when I went there on rather a chilly, windy day with lowering black clouds at the end of the first week of May. First of all, I dashed to the big pond by the Palm House to watch a small girl throwing bread to the ducks. There are some of the most fascinating possible birds in that pond, with absurd red noses and heads that appear to have been carved out of wood and painted by Caran Dache, and their method of suddenly ducking their heads and presenting their tails is infinitely engaging. Then I went into the Palm House itself, not to look at the palms nor wholly to get out of the wind, but in order to enjoy once more the sentimental memories of a beloved greenhouse which always return to me with that heavenly tropical stuffiness. The palms, too, have a little sentiment of their own, because they remind me of an ancient picture of Ali Baba in hiding while the Captain of the Forty Thieves approached the door of his cavern of treasure in the forest.

These two rites having been performed, I looked with rather lack-lustre eyes at the notice board telling me of special objects of interest. Some were unintelligible, but cherries, magnolias and rhododendrons appeared to constitute an inevitable duty. And the most beautiful of them all hit one right between the eyes on leaving the notice board. This was a double-flowered cherry in the full tide of its loveliness, a dream of white, with every single blossom complete and perfect. As I wriggled under the branches to read the name on the label and knocked off one single petal through not stooping low enough, I felt a Goth and a vandal. The magnolias were disappointing by comparison but then I know that I am never worthy of magnolias, which look to me rather too full blown and like ladies who have lost for ever something of youthful slimness. The rhododendrons were very splendid and better still, for me, were just one or two azaleas that had ventured out. To an unflowery person I suppose that flowers are dear not for their own sake but from some association of ideas. Rhododendrons mean a little island in the middle of a lake on a lonely hill in Wales and azaleas mean a particular flower-bed in a Kentish garden, and the azaleas mean most because Kent comes first and Merionethshire second.

Yet there is one thing that I do want to see purely for its own sake at Kew, and that is the blue sea of bluebells. Alas! when I was there it was but a little edging of blue foam on a green sea. One associates bluebells with beech trees that have just put on their new spring clothes. The beeches were almost at their best, so clean and fresh and delicate, but the bluebells were still very few. They looked rather dowdy and bedraggled and as if their poor little noses were only blue with the cold which had tweaked them. Elsewhere, however, there was a compensating stretch of blue. This was where the grape hyacinths were in full glory near a little temple. They were very properly labelled "Heavenly Blue." These, too, had an association of ideas. If it was not actually these very flowers, it was certainly some pretty little cousins of theirs that grew on the bank of a dry river bed where I lived for a while in Macedonia. They brought back the mud-walled houses of a Turkish village, with all the quince trees in blossom, the Belasica mountains behind and in the foreground a Turkish boy, his little stomach enveloped in a big red sash, playing an engrossing game with pebbles from the river bed.

IRIS SIBIRICA AT KEW.

As one wanders through the great spaces of Kew one's surroundings change so much that one's mood must change with them. The bamboo garden gives a feeling of richness

Digitized by Google

A PANORAMIC VIEW OF KEW.

Frontispiece to the Guide to the Royal Botanic Gardens, Kew.

and splendour and luxury. How gorgeous is the name Arundinaria japonica! It is pleasure to roll it out aloud as one might do with the high-sounding titles of an Oriental despot. On the other hand, where the daffodils are growing casually in the grass among the trees, one has the peaceful, sunshiny, homely feeling of an intensely English garden. Then, again, when we are among the fir trees the sun goes in. Everything is dark and gloomy, and we might be in Switzerland or Scotland, in a lonely wood on a lonely hillside.

Finally, to give one more desultory impression, there is one thing at Kew that makes me more ashamed of my ignorance than either the flowers or the trees can do. It must be a delicious place for people who know and love birds. There was at one spot a blackbird which sang to us divinely, but beyond that my mind is a blank. I merely know that there were birds everywhere, that I did not know their names or their songs, and that I felt a sudden desire to look for their nests; only a notice said I must not. But stay! I have forgotten one thing—the pleasantest thing that happened to me at Kew. A dear little robin sat on a *Fraxinus anomala* and looked at us as bold as brass with his beady eye while we stood within a foot of him. I wonder that he does not tell all the other little robins in Surrey and Middlesex to come and live in so agreeable a neighbourhood.

The FINER HYBRID RHODODENDRONS

A FEW weeks ago Mr. Gomer Waterer wrote a most excellent article in THE GARDEN on hardy hybrid rhododendrons. What he says is true, that there is a strain of hardy garden hybrids which are among the most suitable of all rhododendrons for ordinary gardens, that they are very floriferous year after year, that they will stand any amount of frost and will flourish in full sun. Where I might join issue with him is in his general utilisation of rhododendrons, for they are not, and never have been, plants which love the sun; the reason is that they are such typical plants for moderate shade. This can be proved by growing even the hardiest of hardy hybrids in a situation where there is some protection from wind and where the sun does not blaze down on them from sunrise to sunset. You will find that their leaves will grow larger and their brilliant trusses of flower fuller in form and more beautiful in texture.

This was easily seen at one of the Vincent Square Shows of the Royal Horticultural Society, where a plant of Loder's White was staged. Now, this is a rhododendron which is absolutely hardy and yet has the advantage of giving, even in a cold garden, a touch of an exotic look. If grown in a position where it is in moderate shade, it will delight even the most sophisticated by its magnificent rather loose trusses of a pure white opening from rosy buds. The petals are fimbriated and the corolla is often 5ins. in diameter; and this in an ordinary garden. This plant at the Show had tiny leaves and flowers barely an inch and a half in diameter. No doubt this plant was forced for the Show, but it had been so obviously half starved and grown without any protection that it was a pity it had been staged: it certainly did the plant no credit.

Many people are only too inclined to treat all rhododendrons, whether hybrids or species, as they do the common garden varieties, and this is a grave error, for the plants are so obviously unhappy that constant complaint is laid at their door that they are not hardy in that particular garden. All hybrids and species are the better for partial shade and particularly for protection against wind. With these two precautions and with proper feeding the whole of the hybrids mentioned in the latter part of this article are suitable for our gardens unless they are definitely stated as being tender. In an article of this length it is, of course, impossible to mention more than a few successful hybrids, but these included are all well tried plants which already beautify many gardens.

Digitized by Google

DR. STOCKER.—A cross between R. Aucklandii (Griffithianum) and R. caucasicum album, raised by Messrs. R. Veitch and Sons of Exeter. This is a magnificent hybrid with large flowers, resembling R. Aucklandii in shape, carried in a loose truss. The flowers are very wide open, often 4ins. to 5ins. in diameter, white with a few dull crimson spots at the base; the outside of the corolla is faintly tinged with rose. It is very floriferous and rather dwarf in stature, which is an advantage, as some of the Aucklandii crosses are inclined to be long and lanky. It flowers in the first half of May and makes its growth late, so its young shoots are rarely cut by frost.

MANGLESI.—Another fine Aucklandii cross, probably with some catawbiense hybrid. It was raised by Messrs. J. Veitch and Sons at Coombe Wood and was first sent out in 1885. Although fairly well known, there is room for a great many more plants of it in our gardens. The flowers are carried in a large upstanding truss. They are pure white with a few crimson spots on the upper part of the corolla. It is a more vigorous grower than Dr. Stocker and becomes a large plant. It is just as hardy and flowers in May.

BEAUTY OF LITTLEWORTH.—Raised by Mr. J. H. Mangles, it is an Aucklandii cross with notably large foliage and white flowers speckled with dull crimson. As will be seen from the illustration on page 370, the leaves are particularly large for a hybrid, while the flowers make a bold show on the fine conical truss. It flowers in May, and is perhaps not quite so hardy as Manglesi.

IVORY'S SCARLET.—A hybrid from blood-red arboreum, raised by Mr. Ivory, a nurseryman at Dorking about 1850. Mr. Millais calls it one of the "great" rhododendrons that should be in every garden, although at the end of his description he wisely adds the warning that this rhododendron strongly resents full exposure to the sun and drought. The colour is intense, but is, perhaps, more of a rich red than scarlet. It is rather a straggly grower and has to be helped to make a shapely bush. Although very floriferous, it does not flower freely until it is of some size. It flowers in May.

THE UNKNOWN WARRIOR.
A new Dutch hybrid, with rose-pink flowers.

THOMSONI × FORTUNEI.
Raised by Sir Edmund Loder at Leonardslee.

LUSCOMBEI.—R. Fortunei × R. Thomsoni. It has been raised by several growers, including Sir Edmund Loder. Although it flowers in April or early May, it is rarely cut by the frost. The flowers are often 3ins. in diameter, clear rose in colour, and carried on rather a loose truss. This is a most excellent hybrid, very free flowering and adaptable. There is an opposite cross, Thomsoni × Fortunei, with rose flowers of varying intensity; an illustration of some fine trusses of this hybrid is given.

LUSCOMBE'S SCARLET.—The parentage is doubtful. The truss is more compact than in Luscombei, while the colour is a mixture between rose and scarlet. It flowers early in May and is very floriferous.

LODERI.—The best hybrid and probably the finest rhododendron in existence. This famous plant was raised by Sir Edmund Loder and is a cross between R. Aucklandii and R. Fortunei. It grows to a height of 15ft. or more and as much in diameter. The flowers are produced in late May. There are two forms, one with a very loose truss and the other moderately so. The corolla is widely campanulate, often 6 ins. across, while the colour varies from pale pink to pure white. No description or illustration can give a picture in late May of this magnificent plant with its grace, its large foliage and exotic-looking flowers. Although hardy, it is a plant which will not stand full sun or drought. To see it at its best it should be planted alone in thin woodland in a position where it can be admired from all sides. It is best seen with a dark background. Another hybrid of similar parentage is Kewense; although a fine plant and very floriferous, in size and grace it cannot compare with Loderi. It is absolutely hardy and a worthy garden plant.

Two most excellent strains of hybrids have been introduced into commerce by Messrs. C. B. van Ness of Boskoop and Mr. M. Koster, most of them with Aucklandii blood in them. With one or two exceptions they are of extreme hardiness and are of inestimable value to our gardens. They are large-flowered and take the place in cold gardens of those magnificent hybrids which are only hardy in Cornwall. As a rule the colours are rich, while the plants flower at an early stage and are very floriferous. One exception which is not quite hardy is Queen Wilhelmina, owing to the fact that it flowers and makes its

Digitized by Google

growth early in April. The colour is a rich red. Among the best are :

EARL OF ATHLONE.—Large fairly tight trusses of magnificent rich blood-red flowers. It flowers in May and is the nearest in colour to blood-red arboreum that a cold garden can possess. Plants of 2ft. 6ins. will flower freely even in full sun, although the trusses will be larger if it is grown in moderate shade.

UNKNOWN WARRIOR. — A shapely bush with large upstanding trusses of rose-pink flowers in May. It is very floriferous and is an admirable plant in every respect.

GEOFFREY MILLAIS.—Similar to Unknown Warrior, with spotted palest blush flowers.

PRINCESS JULIANA. — The commonest of this strain in our gardens and, to my mind, the least pleasing in colour. The edges of the petals are fimbriated and the trusses are shapely, but in a dull season there is too much blue in the pink to make it attractive. Later the colour fades to a blush white, which is attractive.

KING GEORGE.—A very fine deep rosy-scarlet with buds deeper in colour. It flowers in May and is fairly soft.

R. KEWENSE.
A most floriferous hybrid and absolutely hardy.

ARMISTICE DAY. — Large trusses, deep rose in colour. A very good hybrid.

VAN NESS NO. 300.—A new variety shown by Messrs. van Ness for the first time this year. Pale lilac in colour and slightly fragrant. This is not a common colour in large-flowered hybrids, and so should become very popular. The trusses are large and stand up well.

Many gardeners are now interested in hybridising rhododendrons, and it is certainly a fascinating hobby. There is one word of warning, however, which can be given. Do your hybridising with some definite object in view. It is little use crossing two ordinary garden hybrids, for in form and shape the progeny will be the same as the parents. There is still a great deal of work to be done in providing our gardens with large-flowered lilac and bluish tinged rhododendrons, and also those with yellow and orange flowers. Remember always that the best forms with the largest flowers will produce the best progeny. R. Loderi is a case in point; several growers have tried to get the same result from a similar cross, but never with the success attained in R. Loderi. The reason is obviously the quality of the parents. E. H. M. Cox.

BEAUTY OF LITTLEWORTH.
A fine hybrid, with upstanding truss and large foliage.

GEOFFREY MILLAIS.
A new Dutch hybrid, which will certainly become popular.

A POOR MAN'S PARADISE

BY DION CLAYTON CALTHROP.

OVER the length and breadth of England you will see strange conglomerations of history, colour, arrangement and pride jewelling the roadside. They are the cottage gardens of England, and note also that there are but few homes where no flowers enter. As a race we have a passion for flowers. The Romans left us many great things, and I am inclined to think this gardening mind of ours is not the least of them.

A CHARMING COTTAGE WITH AN OLD ENGLISH GARDEN.

Many a man in England little dreams that where his cottage stands, once, in the Roman days, gentlemen sat drinking Falernian poured out of amphoræ dated with the year of the Consul. There they ate roasted field fares and asparagus, and dates sent from Thebes; and where stood their clipped hedges of yew and box there stands a cottage or two with gardens gracing the road, a windfall of colours for the traveller's eyes. Still less do they realise that the gardeners' patron saint is Saint Fiacre, who gave his name to the French cabs.

There's your man in his shirt and trousers with a belt about his middle and a pipe in his mouth, a brawny brown man used to hedging and ditching, or reaping and sowing, tending his flowers with as much pride as a woman has in her jewels.

There's your cottage thatched with reeds or straw, or tiled with slate or stone, and there's a bit of supper getting ready and a chat with a neighbour and great content.

In English literature, which is rich in descriptions of the country, one gets the two views—the realistic and the ideal. Some writers see nothing but the brute force of nature, the eternal struggle for existence, the harshness of poverty, and others see, more truly, the decorations of life like medal ribbons on a field of khaki. And flowers are bright spots of comfort in a world of doubt.

Your poets' picture is the true one, let the pessimist say what he may. It's a cutting here and a cutting there and a packet of seeds from the village shop (and let me assure you they do come up looking like the coloured pictures on the outside). It is an article of faith that, and a tribute to seedsmen, that marigolds come up looking like marigolds and pinks are pinks, which nobody can deny.

Here we have our history at our door with coloured illustrations. Here's Sir Walter Raleigh looking at you from the eyes of a potato, here's Greece with her currants from Zante, and here's the quince from Crete. Tobacco, that agreeable weed, scents the night air, with stocks and fifty growing things to give you a calendar.

Here's a herb or two for the pot and a bit of lavender to sweeten linen, and what is life without an onion?

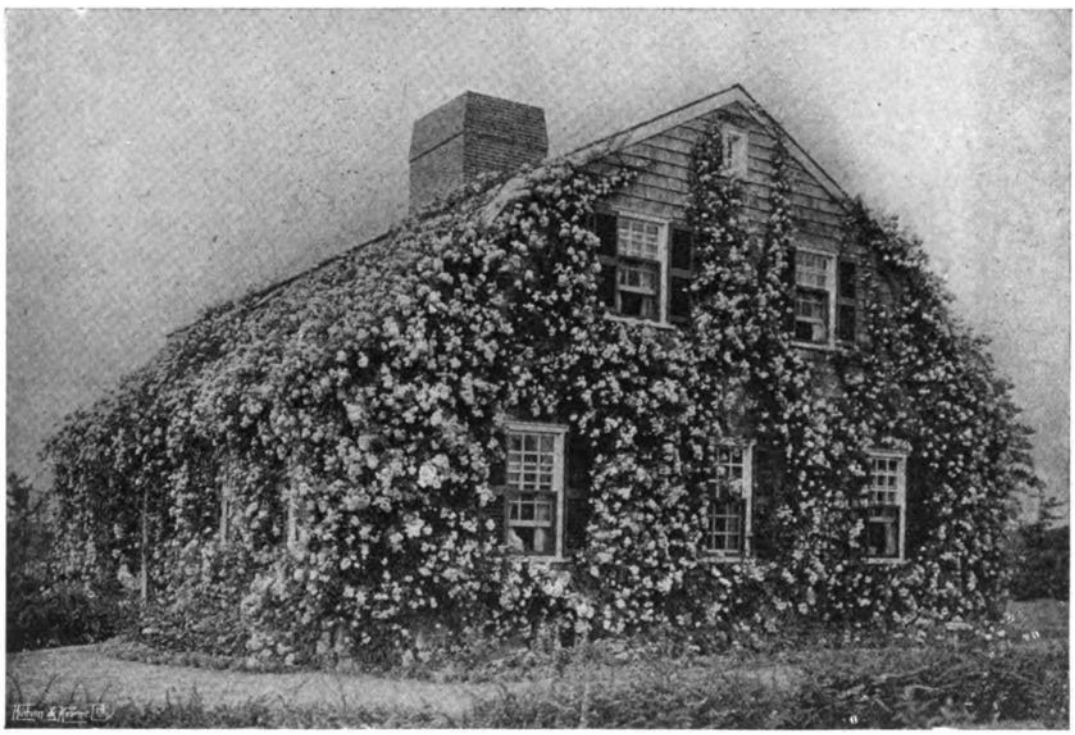
The very names of the flowers have a happy sound, bachelor's button and gillyflower, love-lies-bleeding and heart's-ease. The geranium and the arum the poor man has from Africa, the crocus from Persia with its gorgeous friend, the tulip.

Right up from the gate to the door are ladies and gentlemen, or over the porch and on the window sills, and creepers on the house front maybe, a gnarled old apple tree in the bit of ground at the back, where the lavender bush is to dry your linen on, and a herb or so to pluck at, and poppies to cure the

Digitized by Google

toothache, and aconite for the rheumatics, and tansy or camomile for liver, and hellebore for blisters, you will find them in plenty of gardens; and, as like as not, an old body in a shawl sitting outside doing about five things at once, minding the children, scaring the birds, listening for the kettle to boil, hurroushing a stray dog out of the garden, and keeping a weather eye on the neighbours. She's history is the old dame, she could tell a tale as old as the tale of Noah taking to the water, and does tell a tale, too, if she and you get on together—right from the time when she was in service to the time she married her third husband—and good listening it is too. Maybe a flower will start the tale—those great big sunflowers, for instance—and she's off with the story of the Squire and the Lady from London. You don't have to bother how the story links up with the sunflowers, but it just begins. "I mind the time," and there you are back sixty years, anyhow the year the young Squire set his watch by the sundial of a moonlit night. (Hush!)

Old-fashioned the garden is with those frail pink roses such as you see on Lowestoft bowls, and sweet-scented musk by the way, where has all the sweet-scented musk gone nowadays?), and periwinkles, and those great blue and white striped convolvuli, beloved of the flower painters in the eighteenth century.



A WONDERFUL PROFUSION OF RAMBLER ROSES ON A COTTAGE.

There are other roses in this garden, the York and Lancaster, the cabbage rose and the Seven Sisters, a hollyhock or so and some African marigolds, and, of course, evening primroses. Herrick would have felt quite at home in such a place: even the very wains which pass the door, even the brass ornaments on the horses, are just the same as they were in his day, or for the matter of that, in Chaucer's.

Round at the back (O, I've been all over the place), there are two straw skeps, with wood hoods painted blue, and the alighting board for the bees is white. This is the kitchen garden, a potato patch, a mound with vegetable marrows growing on it, cabbages, sprouts, onions, leeks, a few chives, lettuces and turnips, and all sorts of oddments, but kept as neat as you please.

If you look at the garden on either side you will soon see that our man is a gardener born, and I, for one, don't believe you can make a gardener: he is like the artist, born and not made.

You can tell that his wife is a good housewife by one glance at the parlour, which sparkles with cleanness. A pair of brass candlesticks flank a Dutch clock on a bracket, and there are two spotted dogs on the mantelpiece, and one of those mugs with brown and blue bands and a design of seaweed holds a bunch of lilies of the valley. There are one or two silhouettes and two enlarged photographs (one of a man nearly all beard and a painfully fixed expression and the other of an old woman in her best cap), and there is a church almanack and six very uncomfortable chairs.

I am all for the kitchen myself, where I am allowed to sit on a patchwork cushion in a Windsor chair and there we talk, the man in his socks, for he is not allowed to bring his muddy boots into the house, and he will talk about flowers in just the same way and with the same sense of love and pride as a man who runs an orchid house or an orangery. Indeed, the Squire turns a blind eye when he passes by and sees one of his choicest carnations flourishing away in the front garden, well knowing that the pot of musk in his dressing-room came from the cottage in exchange. And no robbery either, say I. The Squire, let me tell you, being just as at home in that kitchen as in his own drawing-room, and he'll bring his bottle of port and bottle of whiskey round himself on Christmas Eve, and not grocer's port, either, I'd have you know.

I might have forgotten—but, no, I never should—the bush of moss roses in the garden and their persistency in the decoration of the house, pink on the parlour wallpaper, blue in the passage and staircase and figuring in an orgy of sentimentality on a woolwork fire screen. If I had to pick a flower to symbolise the Victorian era I should pick the moss rose, just as I should pick the gardenia for the Edwardian, and harking back to Chaucer's daisy, the Tudor rose, the auricula for King James, and the tulip for William of Orange.

If all this appears to wander, remember that such gardens do give rise to rambling thoughts; they are places in which to cull a posy more than to pick choice exhibition blooms. A thought for a flower, a memory, or perhaps a succession of memories back to the time when one picked daisies and poppies and brought them home in a hot hand as an offering. There, that takes me back to doddering grass at once, and daisy chains, and cowslip balls, and the threaded loops of dandelions one used to make helped by a thorn out of the hedge.

Lucky the man who lives off a main road and does not suffer clouds of dust raised by passing motor cars to smother his garden. Lucky the man who can find comfort and repose after his days work in his garden, with his pipe; enjoying the night scents, the cool of the evening, and the final settling down of a dormitory of starlings.

Once, I was talking to an old gardener by the sea, and two or three seaplanes flew overhead. "Times have changed," I said. He took his pipe out of his mouth and replied, "Well, sir, when I look at the sea and the sky and notice the young folks courting in the lanes, I don't seem to feel they have changed very much."

Flowers and gardeners, I salute you.

FORTHCOMING EVENTS.

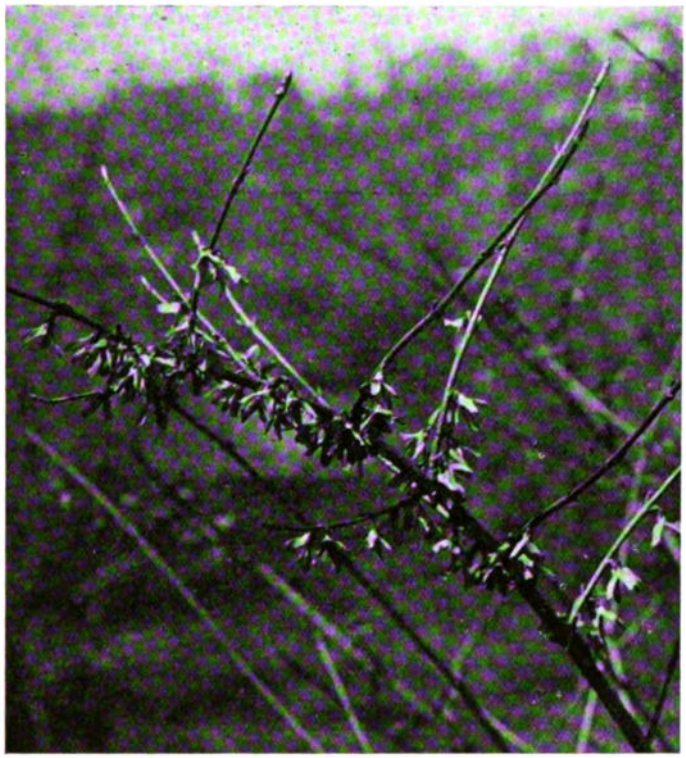
RARE AND NOTEWORTHY PLANTS

BY E. H. WILSON.
OF THE ARNOLD ARBORETUM.

FORSYTHIA OVATA.

THERE are comparatively few Korean plants cultivated in England, though those of the sister countries of Japan and China are among the most valuable material hardy gardens possess. Undoubtedly the best known and most prized Korean plant we have is the lovely Viburnum Carlesii, often carelessly referred to as native of other Eastern lands. Since the annexation of the country by Japan the flora is becoming known and each year good plants are brought into cultivation. Korean plants are hardier than the rank and file of those of China and Japan, but since the flora is boreal in character many are less suited to the English climate. In the milder parts they start into growth early and usually suffer from late frosts. In eastern North America the climate is to their liking and they give maximum returns. In the British Isles these plants should be grown either in the coldest parts or in those favoured with the mildest winters, and then good results would ensue.



A FLOWERING BRANCH OF FORSYTHIA OVATA.

A new and interesting Korean plant is Forsythia ovata from the Diamond Mountains. It was discovered and named by Dr. T. Nakai in 1917 and was brought into cultivation by means of seeds which I collected in the autumn of that year in the type locality. In the Arnold Arboretum the plant, without any special attention, has grown well and flowered for the first time in 1923. This year it is flowering more freely and a better opinion of its garden merits can be formed. The flowers are primrose yellow

A FINE TREE OF CERCIDIPHYLLUM JAPONICUM, 80 FT. TALL GROWING IN NORTHERN JAPAN.

C. JAPONICUM, 40 FT. TALL GROWING IN THE ARNOLD ARBORETUM. THE SEED WAS SOWN IN 1876.

Digitized by Google

in colour, rather small, and are open a week in advance of those of any other species. The leaves are very distinct, being broadly ovate, even rotundate, 2½ins. to 4ins. long, 2ins. to 3½ins. wide, long-pointed and often very coarsely toothed, though sometimes they are more or less entire. The stems are rigid, ascending, clothed with grey bark. How tall this plant will grow in gardens we do not know, but in a wild state I never saw it exceeding 6ft.

In exceptionally severe winters the flower-buds of F. suspensa, F. viridissima and their varieties and hybrids are killed in this Arboretum, though the European species (F. europæa) rarely suffers in this way. If the new Korean Forsythia proves "bud hardy" it will be of exceptional value to northern gardens.

CERCIDIPHYLLUM JAPONICUM.

Not before in the Arnold Arboretum have the trees of Cercidiphyllum japonicum flowered so freely as they are doing at the present time. Every tree is decked with colour, illuminating the landscape from a distance. The male and female flowers of this plant are borne on separate trees. They are naked, produced from short, spur-like shoots; the male flower is a cluster of crimson stamens with long anthers suspended from thread-like filaments; the female consists of two long divergent crimson pistils. The aggregate number of flowers is enormous, and the whole tree appears flushed with bright crimson. The leaves unfold immediately the flowers fade and are at first bronzy crimson and singularly pleasing to look upon; in the autumn they become brilliantly tinted with yellow, orange and scarlet. In shape the leaves resemble those of the Judas-tree, hence the generic name.

The cercidiphyllum trees in this Arboretum were raised from seeds received from Hokkaido in 1876. The trees have grown very well, the tallest being fully 40ft. high with a trunk 6ft. in girth; they flower freely and have ripened their curious fruit pods regularly each season for twenty years past. In outline the crown is broadly ovoid and made up of innumerable ascending-spreading and twiggy branchlets.

Some years ago an animated controversy was carried on in English gardening papers as to whether Cercidiphyllum was a bush or a tree. As a matter of fact, cercidiphyllum is one of the world's noblest trees and grows to a larger size than any other deciduous-leafed tree indigenous in north-eastern Asia. It is native of Japan and of interior China, where I once measured a tree 55ft. in girth of trunk; but more usually the trunk circumference of cercidiphyllum is from 20ft. to 30ft., and from 70ft. to 80ft. high. In Japan, where it is known as the Katsura, the wood is valued for planking and general building purposes.

GARDENS OF INDIA

BY SIR GEORGE WATT.

(*Continued from page* 286.)

THEIR gardens contain an assemblage of plants of this nature, peculiar and characteristic. Among these the following may be mentioned: Malva verticillata, the mallow or *lapha-sag;* Chrysanthemum coronarium, the *babir*, not met with in any other part of India though common in China; Rumex vesicarius, the sorrel, regularly eaten as a *sag* and also an extremely handsome plant, well worthy of a place in the ornamental garden; and lastly, Brassica cuneifolia, found in nearly every one of the Northern Bengal to Assam vegetable gardens. That remarkable plant forms a rosette of dark bluish-green leaves, having broad yellow midribs and leaf stalks. When young it looks not unlike a Chinese cabbage, but in time it becomes more like a sprouting broccoli and shoots up a much-branched inflorescence to a height of 6ft. All parts are eaten, especially the young flowering shoots and tender leaves. It is generally known as *lai-hak*, which might be translated as *mustard-sag*. It is nowhere met with outside the region indicated. But perhaps the greatest novelty is the edible chrysanthemum. While not exactly an ornamental species, when seen in compact plots, the erect sparsely branched stems with their crowded yellow heads make a good show. But the startling thing about most of the plants in the Northern Bengal and Assam gardens is their strongly Chinese feeling, this is the more significant since the people are also distinctly of the Mongolian type.

THE FLOWERS.—Such then are some of the chief fruits and vegetables of the peasant garden, so I must now hasten to tell you something about the flowers likely to be seen there. Right in front of the house door, very possibly, will be found a plant of the sacred *tulsi* (Ocymum basilicum), a plant that cannot be omitted since, through its cultivation, the favour of the gods is not only thereby secured, but the plant itself is believed to purify the atmosphere and to kill mosquitoes, so it is invaluable. The oleander or *kaner* (Nerium odorum) in a like manner has the reputation of being able to protect the household from malaria, so it also must be found a place. Moreover, and as a matter of business, the *kaner* must not be overlooked since in the garland trade it has few equals, and possesses the additional merit that it can be presented to all the gods. Then the bush *tagar* or *chándui* (Tabernæmontana coronaria), with its sweetly scented flowers (as its specific name implies), might be spoken of as *the* garland flower of India. Fortunately, it flowers throughout the year and there are single and double flowered forms. Roxburgh (the father of Indian botany), truly observes that few shrubs surpass in beauty the double-flowered *tagar*. The *gandharaj* (Gardenia florida), a Chinese and Japanese bush, is sometimes cultivated as a substitute for the *tagar* and there are both single and double-flowered forms, sweetly perfumed.

The *har* or *harsinghar* (Nyctanthes Arbor-tristis), is a shrub much admired by the Natives of India; it has the habit of shedding its flowers in the early morning. The orange-coloured tubes of the corollas are picked off from the white limbs, and from the tubes, thus laboriously collected, a golden yellow dye is obtained. The flowers have also a sweet perfume, like that of the jasmine. The *harsinghar*, according to a Hindoo tradition, is said to have been brought from heaven by the god Krishna. Still another story tells of the bush having been a king's daughter who fell in love with the sun, but being repulsed, ever after refused to look on it again, hence the well known fact of the flowers falling before the sun rises. Mimusops Elengi has the same property of shedding its flowers at break of day. Both these flowers are highly valued in the garland trade.

But the mali or garland-maker must possess a jasmine or two and the species most generally met with are the Arabian or *mogra*, the *bel* (Jasminum Sambac), which is much admired for votive offerings in certain religious ceremonies; moreover, the flowers constitute one of the darts of Kama-Deva, the Hindu god of love. Then again, the Spanish jasmine, *chameli* (J. grandiflorum), was highly commended by the Emperor Baber in 1519. But it is to-day more valued as a perfume and medicine than as a garland flower.

A member of the Amaryllis family, the *dapidhupi* (Crinum latifolium), is a most stately plant, in blossom during the rains. Room for it is found, as a rule, near the well, where it may secure a daily supply of water. Recently, another Amaryllid has been introduced to Indian gardens—the *gulshab* or *rajani-gandha*, the tuberose (Polianthes tuberosa). It has been given an honoured place in the peasant garden, but more, in response to the demand for the flowers in the extraction of attar of tuberose, than as a garland flower.

ORNAMENTAL FLOWERS.—Most of the flowers already mentioned, it will be observed, are natives of India. They constitute a series very possibly not unlike that grown in the gardens of the malis centuries ago. Flowers not used for religious observances, naturally, are more subject to the caprice of the cultivator. Hence one might be permitted the observation that the choice of foreign flowers has in many cases been unfortunate. Two more discordant notes (both in colour and form) could hardly have been struck than the introduction, first of the *genda* or marigold (Tagetes erecta); to-day its flower heads are strung into garlands and these are even hung round the idols, so that the *genda* has, it would seem, been adopted as a sacred plant; second: the yellow, purple or magenta flowers of the *gulabbas* or *krishnakeli*, the Marvel of Peru (Mirabilis Jalapa), a plant that is leaving the gardens and becoming so prevalent near villages as to exclude all other vegetation. It is, in fact, following closely on the *sial-kanta*, the Mexican or prickly-poppy (Argemone mexicana), now no longer cultivated, for it has assumed everywhere the condition of a pestilent weed.

The ornamental flowers met with in the peasant gardens had better, however, be left over till we come to deal with the Native gentleman's garden. The following may be accepted as the more constant: The *joba* (Hibiscus rosa-sinensis); the *krishna-chura* or Barbados pride (Cæsalpinia pulcherrima), an introduced plant now met with in every garden in India; the *galub* (Rosa damascena), the Damask or Persian rose; the *rangan* or flame-tree (Ixora coccinea); the red periwinkle or *sadaphul* (Vinca rosea), and a West Indian plant rapidly becoming a weed.

THE GREAT CHELSEA SHOW

May 26th, 27th and 28th

CHELSEA this year promises to exceed that of any other year, not only in the numbers of visitors, but also in the quantity and brilliance of the exhibits. The colour is particularly brilliant this year, perhaps partly owing to the cold winter and the late season, which has brought on plants with a rush, without any time to allow them to fade in the bud owing to strong sunlight. Their Majesties, the King and Queen, have again graced the Show with their presence, and were noticeably interested in many of the exhibits. Other Royal visitors were the Queen of Rumania, accompanied by her two children, and the Duke of Connaught. We are sure that this Show will be more than satisfactory from everybody's point of view, and from personal experience we are sure that the exhibitors deserve every encouragement. They have worked early and late in the past few days, and few people can realise the amount of labour entailed in preparing every exhibit, however small. Plants have had to be brought up a long distance from the country, and to see them as we are now able to—both in the tents and outside—shows not only skilful cultivation and careful packing, but also a capacity for taking pains. Chelsea opens in fine weather, with a promise of clouds and a few rainy periods in the forecast. Let us hope they do not materialise. At any rate, it is a vast improvement on last year's horrible experience of rain and storm.

MR. CLARENCE ELLIOTT'S ROCKERY. THE BRILLIANT AQUILEGIA GLANDULOSA WILL BE SEEN IN THE BACKGROUND.

ROCK GARDENS

Although many different styles have been evolved during the recent and widespread development of rock gardening, yet the majority of the exhibitors at Chelsea still remain faithful to a type, composed of a waterfall and a stream bordered with rocks, that seems to have become classical for show purposes.

This type is handled with the most immediately striking and brilliant effect by Mr. G. G. Whitelegg, whose stream lies in a rocky valley, with its 9 wide ledges heavily planted in drifts of colour. The dominant note on one side is given by masses of creamy white Saxifraga lantoscana, backed by the cool blue of Veronica gentianoides; while, on the other side of the stream, sheets of pink lead up, through the rather harsh magenta pink of Phlox Vivid, to a group of orange and violet blue in the background, formed by the double Welsh poppy and Aquilegia alpina. In the foreground by the stream-side is a delicate, cool-coloured group of grey powdered Primula pulverulenta in a setting of blue-grey grass; while the central point of the picture is a single plant of Ourisia coccinea in orange-scarlet. The whole effect is very brilliant, but in spite of the studied arrangement of colours the impression it gives is rather uncomfortable; there is, perhaps, too much unrelieved colour, and the general feeling is rather that of a carefully irregular piece of bedding-out than of the brilliant but always congruous association of alpine plants in their natural setting.

MR. WHITELEGG'S ROCK GARDEN.

Messrs. T. R. Hayes use their rock-bordered stream (which is a reproduction of a little piece of Westmorland scenery) with rather more restraint. Their weather and water worn rocks are of great individual beauty and would make a satisfying picture with only the slightest planting; there is one especially fine old channelled boulder lying in the stream bed in the foreground. Very good use is made of dwarf conifers; many of them are being shown for the first time, such as Abies Forrestii, a completely prostrate fir with the tough, wind-swept look of a true high alpine; this is the chief ornament of a large boulder cropping up out of the turf in the foreground and planted discreetly with grey and bronze sedums. One or two of the little cypress-shaped junipers and a small group of Gentian verna grow in the turf at its foot. T

Digitized by Google

boulder is really a little rock garden in itself and a style independent of the stream and waterfall; it could be placed naturally in the lawn of many a small garden where the more ambitious sort would be extravagantly out of place, only—it requires the greatest strength of mind not to overplant it. Two other very attractive dwarf conifers in this garden are a flat-growing form of the deodar and that solid little hedgehog Picea excelsa echiniformis, very effectively planted up against a boulder, and the pleasantest piece of grouping (to one visitor, at least) in all the rock gardens, is a clump of the soft pink Cypripedium spectabilis against a background of grey limestone and the dark green of Picea Remontii.

The Backhouse Nurseries obtain a brilliant effect by backing their stream with Kurume azaleas, Japanese maples and Rhododendron Pink Pearl, the rather emphatic splendour of which a little overpowers a fine group of Antirrhinum Asarina, trailing its creamy yellow flowers over the face of a grey rock. Another modest beauty is Viola Hazlemere, a little pansy of which the colour is very difficult to describe, and very charming; perhaps a pinkish lilac washed over with grey most nearly fits it.

Messrs. Hodson's, Limited, vary the theme by introducing a satisfactory-looking "moraine" garden, a shelving valley of scree, alongside their stream; but it is a pity that this, the only example of its kind exhibited as part of a general scheme, should be planted with drifts of Lithospermum Heavenly Blue, yellow sedum, etc., instead of with the typical scree plants.

Messrs. Cutbush dispense with the stream and waterfall and build up, instead, a narrow gorge, planted with fine specimens of hardy ferns and lit up by a clump of trollius and Primula japonica. Beside the entrance of the gorge is an interesting holly, dwarfish and small-leafed, Ilex Pernyi that should make a useful bush for the higher slopes and background of the rock garden.

Messrs. Pulham and Son's stream meanders very pleasantly, and has three waterfalls. An interesting little cotoneaster overhangs the stream in the background, a new introduction of Mr. Forrest's from China. It has all the distinction of design of the best of its family, and the grey green leaves tone pleasantly with a bush of Senecio Grayii behind it.

Mr. Clarence Elliott breaks away altogether from the classical type of the show rock garden, with a steep cliff of which the upper ledges are thickly planted with Aquilegia glandulosa, solid lines of ivory white and powder blue against a background of grey stone and dark green conifers. The great widespread flowers show to best advantage nodding down, as here, from above eye level; but it is worth noting that these sturdy plants, some of which have between thirty and forty blossoms, have been grown in ordinary stiff loam in open beds, which should encourage a bolder treatment for one of the most beautiful of hardy plants and find them a place in the choice border. Over against the cliff is a little conical mountain, one slope occupied by a forest of dwarf junipers with a plant or two of a special dwarf form of Rosa alpina at the base; the other slope planted with wahlenbergias, pentstemons and Asperula Gussonii. But the most original development of rock gardening is shown in the stone sinks and pig troughs (the incongruity of their association with alpine plants is merely verbal), which Mr. Elliott exhibited for the first time last year. These illustrate, in their small compass, three distinct types of rock garden: a "scree" garden, containing Linaria alpina, Gentiana verna, achillea, etc.; an "alpine lawn," a close mat of thymes, Dianthus Musalæ, Arenaria verna and other little plants that are naturally companionable; and a boulder, with Wahlenbergia serpyllifolia major streaming out from under it over the rough edge of the sink, and saxatile plants long established in its crevices—a square foot of alpine scenery with all the charm that comes of intimate association between the plant and its setting.

FORMAL GARDENS

One of the outstanding features of Chelsea is formed by the life-size gardens, complete with their walls and paths, terraces and fountains, which enable one—or *should* enable one—to judge of the work of some of the bigger landscape firms at first hand. These gardens are this year inferior in quality (taken as a whole), to those to which we have for some years now been accustomed. Stonework, timber, paving, statuary and water are as lavishly employed as ever, but the results achieved are not—except in one or two cases—commensurate with the outlay. Better luck, perhaps, in 1925!

MESSRS. CARTER'S FORMAL GARDEN.

Messrs. J. Cheal and Sons, the well known Crawley firm, have a rather attractive arrangement for an ordinary rectangular suburban garden. The outer borders are filled with miscellaneous plantings, while a large part of the centre is devoted to beds of polyantha roses and a little circular sunken pool garden. The pool garden is very nicely proportioned and good to look upon, but two beds of polyantha roses break up the view of it from the house; these would be better on the farther side. The bottom portion of the garden is devoted to fruit trees, while the "herbaceous walk" through it is planted with dahlias. In addition Messrs. Cheal have an avenue of topiary.

Mr. James MacDonald once again exhibits a formal garden of grasses and this is very tastefully laid out, albeit the rather broad paths—for the great Chelsea public—would look better covered with granite chippings than with the rather nondescript gravel employed. Not the least notable feature is a *hedge* of grasses—mainly well grown plants of Miscanthus japonicus gracillimus.

Mr. Herbert Brook has a small garden featuring much rough walling and rougher paving.

Messrs. Kent and Brydon have a quite small, but very pleasing little formal garden, planted with Japanese maples and choice rock garden plants.

The Horsecombe Quarries display all kinds of stone garden ornaments and, mistakenly as we think, attempt to make with them a formal garden.

Messrs. Italia House, Limited, stage a garden with much walling and paving which in fact gives as much of the Italian feeling as is desirable in an English garden. One enters between a pair of roofed colonnades and the bottom end of the garden is dominated by rather an attractive terrace with rubble walling and easily graded stairways.

Messrs. Wm. Wood and Sons have a quiet little formal garden and a paved wooden pergola among a fine display of their garden furniture and statuary.

Mr. John Klinkert has a garden of topiary, which, judging by the "Mounts" at Packwood and elsewhere, would greatly have intrigued our forefathers. The topiary is excellent.

Messrs. W. H. Gaze and Son have an attractive and very restful garden in the Old English manner, the colour being provided by orange azaleas and mauve aubrietias. The inevitable central pool takes the form of a Maltese cross. On the whole we believe this to be the most entirely satisfying exhibition garden Messrs. Gaze have done.

Messrs. Carter of Raynes Park have a rhododendron garden, with garden shelter complete, which encloses a formal sunken pool of rather elaborate—dare we say too elaborate—shape. Pool and garden alike are dwarfed by an over-powerful fountain.

Messrs. R. Neal and Sons, Wandsworth, have one of the best positions in the Show and have erected thereon a doubtless very expensive and quite spectacular garden. Rhododendrons are largely employed for the planting, and the colour combinations are daring in the extreme.

ROSES

It might have been the "Flaming Month of June" to see the masses of glorious roses in the tents; they are shown in such generous quantities and of such excellence.

Time was, and it does not seem so very long ago, when most of the roses at the Spring Show were exhibited as cut flowers, but the scene has changed and it is profusely-flowered

Digitized by Google

ROSE ROSELINDA SHOWN BY MESSRS. STUART LOW AND CO.

pot plants that now predominate. Almost any and every type and variety have been pressed into service, and the growers have been equally successful with all. To the lover of garden roses there are numbers of the best Hybrid Tea varieties, both the newest and the older, tried favourites. The lover of Nature's species will be charmed with the pillars of Rosa altaica in the collection of Mr. Elisha J. Hicks, for there he shows it in unaccustomed luxuriance. The roundish single blooms are larger and of a clearer white than usual and they are very freely produced As shown it is quite a desirable rose for a dwarf pillar or as a bush in the shrubbery. In the same collection Rosa Willmottiæ, a dwarfer species with pink flowers, is also of interest. In this generous group the free-flowering varieties include Double Orleans of great beauty, Lady Swathling, Lady Reading and Coral Cluster. Among the large-flowered sorts are Premier, Margaret Horton, Rev. F. Page-Roberts and Clovelly.

Rosa altaica is also shown by the Rev. J. H. Pemberton adjoining a vase of R. sinica Anemone of lovely pink colour. Chatillon Rose might be termed a glorified wild rose, for it has much of its appearance but with immensely improved colouring, though it is a real dwarf polyantha. Carrie Koster, White Echo and Edith Cavell are also especially well shown. At one end of his collection Mr. Pemberton shows a vase of a dazzling polyantha said to be a sport from Edith Cavell. This appears to be almost, if not quite, identical with La Reine Elisabeth, which, shown as half-standards, is so striking in the collection of Messrs. F. Cant and Co. In their back row they have a number of tall cluster varieties of considerable beauty. Exhibition boxes placed along the front contain many desirable sorts, such as Capt. F. S. Harvey Cant, which is also to be seen in a large group, Premier and Lady Alice Stanley.

Phyllis Bide, shown by Mr. George Prince, is described as a new perpetual climbing polyantha, and its uncommon orange salmon colouring attracts attention. Edith Cavell, Souv. de Claudius Pernet, Mr. Henry Morse and Hoosier Beauty are all of merit.

As at the N.R.S. Spring Show, Messrs. A. J. and C. Allen have cluster varieties bearing a great wealth of bloom. Romeo, Thousand Beauties, Chatillon Rambler, Excelsa and Paul's Scarlet Climber are noteworthy examples, while among their excellent dwarf pot plants may be mentioned Columbia, America and Hoosier Beauty. Of their newer roses Albertine, a double-flowered copper salmon coloured climber, Papa Gouchalt, another climber of deep pink colouring, and Pilgrim, which is much like a larger and more pointed La France, are of much more than average merit.

In a corner space Messrs. W. Cutbush and Sons have a pretty group of such free-flowering roses as Red Explorer, American Pillar and Hiawatha of the taller sorts, with Orange King, Greta Kluis, Salmon Queen and Mrs. W. H. Cutbush of the dwarfs.

Messrs. B. R. Cant and Sons have an interesting collection on a stretch of tabling where they show Padre, Hiawatha, Sovereign, Covent Garden, Blush Rambler, Thousand Beauties, Orange King, with other good sorts.

A magnificent group of pot plants has been well set up by Messrs. Chaplin Brothers, and this is noteworthy for quantity and quality of bloom. The tall varieties include American Pillar, Dorothy Perkins and the white variety, Blush Rambler and Sodenia. Among the dwarf Hybrid Tea sorts William Bowyer and Agnes Glover, two dark maroon crimson varieties; Florence, rich pink; Mrs. Tresham Gilbey, pale salmon pink; and Mrs. Henry Bowles are all very charming.

Mr. Charles Turner has placed his collection of roses behind many excellent lilacs. The chief of the roses are Mrs. T. Roosevelt, Souv. de Claudius Pernet, Countess of Gosford and La France.

Vases of fresh-cut roses are shown by Messrs. Ernest Paul and Co. Madame Butterfly, Mrs. Henry Morse, Hoosier Beauty, Ophelia, Mrs. John Laing and Covent Garden are the principal sorts. In the Orchid Tent, Messrs. Wheatcroft Bros. have a small collection, in which Coral Cluster and Jessie are prominent.

Messrs. Stuart Low and Co. are showing their new rose, which is a sport from Golden Ophelia. It excels the original both in colour and size. The centre of the flower is orange golden. This rose is sweetly fragrant.

TREES AND SHRUBS

This year, a certain number of the trees and shrubs, perhaps more than usual, particularly rhododendrons, are being shown in formal and informal gardens. These will be found under a separate heading. Messrs. Wallace are showing a magnificent group of azaleas and hardy hybrids at the bottom of the Sundries Avenue. The colours of the azaleas are particularly fine owing to the fact that they have all been grown outside and are not forced for the occasion. The two most noticeable plants on this stand are Koster's Red, which is really a flaming vermilion in colour, and the other Dr. Oosthoek, of which the colour is quite impossible to describe. It is, perhaps, closest to that of a roaring fire on a cold, frosty night.

Another exhibit outside, at the entrance to the main tent, by Messrs. Charlton and Sons, is rather spoilt by overcrowding. They have a large space, and if only some exhibitors would realise that the public is often as much attracted by individual plants well grown and well shown as by a crowded exhibit, they might find these shows more satisfactory from the point of view of orders. Messrs. Charlton show maples, azaleas, hardy vines, hardy hybrid rhododendrons and Populus lasiocarpa, a most attractive species, with large leaves, which should be more often seen in our gardens.

Messrs. Koster and Sons have a fine exhibit opposite the entrance to the main tent of their seedling azaleas, some of which are particularly brilliant in colour, especially those of flaming orange.

Messrs. Cutbush's outside exhibit consists entirely of topiary trees, which show excellent craftsmanship in cultivation.

At the entrance to the main gate is Messrs. Fromow's exhibit of their well known maples. As usual, this exhibit is one of the most interesting of all in the entire Show. Among many fine varieties Acer dissectum palmatifidum and Acer dissectum ornatum are very fine. The latter is pleasantly flushed with purple and young leaves.

Messrs. Cuthbert have a magnificent collection of azaleas of all shapes and sizes. Their corner of the main tent is probably

MESSRS. ALLEN'S ROSES.

Digitized by Google

the most brilliant in the exhibit, but the azaleas lend themselves to colour grouping. Their Azalea mollis x sinensis are, as usual, the most noticeable, among them being Radiancy, a fiery red of very pure tone, and Apple Blossom, which is a true name, for the colours are exactly similar in their soft pinks and whites to apple blossom. They are also showing a very fine altaclarense hybrid of a pure canary yellow called Sunbeam.

The Donard Nursery Co. are staging a most interesting exhibit of trees and shrubs. Skimmia fragrans with its strong wholesome scent is a most attractive plant in a garden. Enkianthus campanulatus is also seen on this stand; it is a more bushy grower than the more common E. japonicus, but is otherwise similar in appearance, with its hanging bells almost coppery in colour. Two softish plants that are noteworthy are Pittosporum Silver Queen, a fine hybrid of their own raising with an almost metallic sheen on its leaves, and Lomatia pinnatifolia with heavily cut foliage.

Mr. Notcutt is showing brooms, azaleas, lilacs and other plants, but the finest are the brooms. His collection is well worth a close examination, for it contains many uncommon varieties. The more common Cytisus fulgens and Beani are to be found, but also C. versicolor of a pleasant greeny white, and C. among them R. Keysii, a peculiar Himalayan species with tubular orange flowers, and R. Elizabethæ, a hybrid from R. Falconeri. On his stand are also shrubs, such as Enkianthus japonicus.

The Yokohama Nurseries are showing their dwarfed trees, which are so well known that they require little comment. They also have several plants of Quercus dentata, which only arrived a week or so ago from Japan. This handsome species, with its large cut leaves, and others travel well to this country, which is surprising, but deaths on the journey are remarkably few.

Messrs. M. Koster and Sons also have a most attractive exhibit of their fine hybrid rhododendrons inside the tent. No. 150 is a pure crimson with darker spots, in an upstarting truss. Robt. Wallace is a fine rose, but probably the best plant on their stand is Peter Koster, a rose-carmine with particularly open flowers.

The Orpington Nurseries have an attractive stand of hardy hybrid rhododendrons, azaleas and some fine bushes of Cytisus Dallimorei.

Mr. T. Lewis also showed hardy hybrid rhododendrons and two very fine new azaleas, King Albert, a good orange, and Seedling No. 1, which is quite equal to the famous Dr. Oosthoek in colour.

THE RHODODENDRON EXHIBIT OF THE LADY ABERCONWAY AND THE HON. H. D. MCLAREN.

sessifolius, feathery in habit and of a clear soft yellow. In a vase on this stand is a magnificent spray of the single scarlet thorn, a plant which should not be despised.

Lilacs and roses are exhibited by Mr. Charles Turner. The roses are noticed elsewhere, but his lilacs are causing great enthusiasm. Among the best are Princess Clementina, a new large semi-double white; Mme. F. Morel, lilac with a dark reverse in particularly large trusses; M. de Messemæcher, the inside of the flower a deeper purple than that of Louis Spath, with a lighter reverse. This last is very fine indeed.

Messrs. Hillier and Sons are showing a fine collection of trees and shrubs, including wistarias, bamboos, syringas, etc. Many of the plants are Chinese species, and no doubt in time will become common in our gardens. Populus Wilsoni has magnificent large leaves, even larger than P. lasiocarpa; Salix magnifica is another large-leaved Asiatic species which looks soft and is not. Then there is Syringa reflexa, a fine species with rose flowers; the raceme as it ages bends over and hangs down. One other plant must be mentioned, and that is Raphiolepis Delacouri, with soft rose stars; this is also apparently hardy.

Next to Messrs. Hillier is Mr. Reuthe, who, as usual, is showing his well known rhododendrons, both species and hybrids;

Messrs. John Waterer, Sons and Crisp have an attractive exhibit of their famous hardy hybrid rhododendrons, among them Pink Pearl, Mrs. E. C. Stirling, Cynthia and Bagshot Ruby; the last is still one of the best hardy reds in existence.

Another exhibit of hardy rhododendrons was that of Messrs. Fletcher Brothers, who also staged several bushes of cytisus.

Messrs. Robt. Green are showing a collection of clipped bays at the entrance of one of the tents and a fine collection of ornamental palms inside. On Messrs. Gills' stand are seen the last of the Cornish rhododendrons in flower. It is rather late on in the season for this genus in Cornwall. Among other plants they are staging Clianthus puniceus, that valuable New Zealand climber, both the familiar red form and a less common and just as attractive white variety. There are also Drimys Winteri, olearias and abutilons. The Lady Aberconway and the Hon. H. D. McLaren have a magnificent exhibit of rhododendrons from their Welsh garden. R. callimorphum, with its rose-coloured bells is excellent, so also are the flat platter-shaped flowers of R. Soulei, both pink and white, the latter most effective. There is also on this exhibit fine vases of such semi-hardy rhododendrons as Lindleyi, Lady Alice Fitzwilliams, and fragrantissima. These have all been grown in the open. One shrub on their exhibit is worth noticing, Corokia Cotoneaster, perfectly hardy and charming. Its twigs are even more twisted than the more common Corokia virgata. Messrs. Cheal's have an attractive exhibit of hardy trees and shrubs in a corner of the main tent. Among them are Corokia virgata, Hydrangea Sargentiana, Enkianthus cernuus and numerous Japanese azaleas.

Messrs. Russell and Co., Limited, have a large exhibit of ornamental trees and shrubs in the open. Cytisuses, acers, wistarias, rhododendrons and azaleas, and clematises are conspicuous. Close by are several specimens of topiary work.

IRISES

Fleur de luce—the flower of light. Truly irises are, above all flowers, lovers of the sun and the open, and in the comparatively subdued light of the exhibition tent the full beauty of their colours is partly lost. Especially is this so with the violet-blues and the blended; the yellow variegatas and the rich red purples are less affected. Also the best effect is attained if we look a little down on them, just as we see them when growing naturally in the open. This is admirably exemplified at Chelsea in Messrs. Bunyard's and Messrs. Wallace's exhibits, the plants being grouped on slightly raised and very naturally formed borders. Considering the late season and interminable wet weather, these two exhibits are wonderful and divide the honours for irises at Chelsea this year. Both contain many of the latest varieties in splendid condition. The Wallace display is more open and extended, while Bunyard's is perhaps the finest and most artistically arranged massing of bearded irises ever seen at Chelsea.

Of the individual flowers there is only space to mention the most notable. But this does not mean merely the newest and latest arrivals. Princess Beatrice is still without a rival among the pale violet-blue pallidas. Queen of May, Alcazar and Isolene are still in the front rank. Jacquesiana still holds its own, though over sixty years old. There is a large group now of this type—the red squalens type—all of which are desirable and satisfy varying tastes. Prosper Laugier and Ambigu are rather deeper toned, and Rosalba, shown by Messrs. Bunyard, is a more self red toned flower and the best for massing. Opera and Archeveque are a little nearer the red pallida or red bicolor type and the latter rather dwarf. Seminole is the finest in colour, form and habit of all these. These red-toned irises are coming more into favour, since it is realised how beautiful they are as cut flowers by artificial light, for which purpose the violet-coloured iris are unsuitable. Among the lighter red purples Ed. Michel is still good, but Miss Sturtevant's Dream, shown by Wallace, is more beautiful in colour, a self lilac rose; while Mr. Dyke's Aphrodite, shown by Bunyard, is the best of these. In Wallace's display may also be seen the new Lady Byng and Queen Caterina, both of a beautiful clear rose-mauve, and the latter with a lustre unsurpassed by any other iris, but needing the full sun for its perfect display.

There are so many of the violet-blue Trojana hybrids that it is difficult to choose. Lord of June, Morwell Angelo and many others are all fine, but perhaps the best seen to-day is Ann Page, shown by Wallace. of the specially blue-toned irises, Crusader is shown in fine form by Bunyard and Blue Bird by Wallace, but brighter and bluer than either is Leoné Trenance with flowers of very fine form. Azure may also be noted together with these, though it is a bicolor.

Digitized by Google

Of the outstanding varieties to be seen at Chelsea this year the two most notable are shown by Wallace. Theseus is a splendid large-flowered white raised by Sir A. Hort. Though its parentage is unknown, it has every appearance of being a union of Kashmir White and a Trojana hybrid. Tall and of fine Trojana habit, it has also the Trojana form of flower and strong olive yellow reticulations. Pioneer, of which Messrs. Wallace show a fine group, is now the finest of all the deep red-purples. The flowers are very large and of the finest form, and the colour rich and deep. It is early, very strong-growing and very free-flowering, being derived from Germanica through Paladin (which may be seen in fine form in Messrs. Bunyard's display). These two are now shown for the first time. Others that, though no longer new, are still among the best of irises, include magnifica, one of the largest and quite the finest formed iris yet raised—with a little more substance it would be almost perfect. Messrs. Wallace also show Ambassadeur, which is equal to all but the best of the Dominion race and has the same rich velvety falls, darker even than Moa. Bruno, probably the richest coloured iris yet raised, but weakened somewhat from forcing. Lent A. Williamson, likewise somewhat weakened in colour, and Mr. Yeld's stately Asia and Prospero. A good group of Denis' Dalila, always a striking iris in the border, is also shown.

Souvenir Mme. de Gaudichau is shown both by Wallace and Bunyard, though the colour is not so rich as when seen in the open. It is quite the best self deep violet purple iris and wonderfully free-flowering. Citronella is to be seen near Bruno, and maintains its reputation as the most beautiful iris shown, in spite of the median line in the falls that some think a blemish.

In Messrs. Bunyard's display, besides others already mentioned, may be seen Glamour, one of the fine Dominion race, and the nearest of these to a red squalens type; indeed, it might almost be described as an enormous Jacquesiana. Also Titan, so fine in form and size, but less distinguished in colour than others of Dominion's progeny.

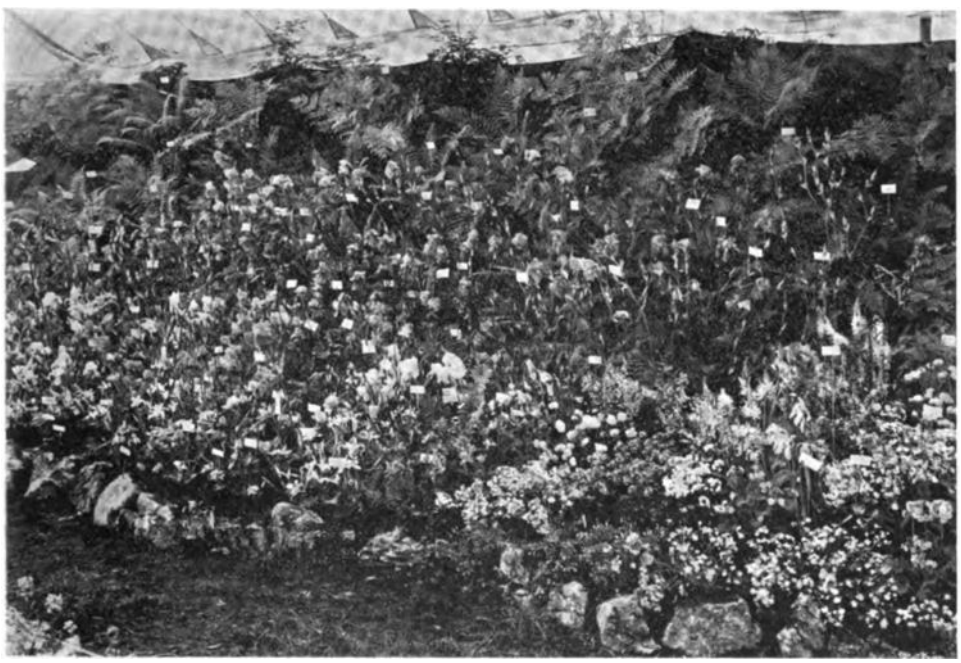
Few Plicates are to be seen, but in Messrs. Bunyard's exhibit is the beautiful Mme. Chobaut, a squalens-plicata. The colouring baffles description—cream tinged yellow and margined in the standards with a veining of pale wine colour, and in the falls with lilac shading to brown at the hafts.

The Orpington Nurseries make a large display on raised staging. This is more convenient perhaps for examination of individual flowers of special merit such as this firm specialises in, but it makes a less effective display as a whole. The season has been too unkind for their finest varieties, which are of midseason flowering. Those worth noting include Istria, a white of a pleasing greenish tone and faintly tinged porcelain. Sapphire, one of the best of the Ciengialti hybrids. Turbine, one of the best of the rose mauves for artificial light and very early; and Cretan, a deep rich violet purple species from Mr. Dykes' collection.

Mr. Perry has, as usual, a beautifully displayed exhibit, but owing to the late season is unable to show any of his fine new Barbata iris seedlings. Some very interesting hybrids of the Californian Apogons are to be seen, such as Douglasiana × bracteata, and a fine display of the Regelio-cyclus hybrids, including Artemis, Psyche, Luna with its blue beard, Charon and stolonifera.

Lastly, Hoogiana is shown by many growers. A most beautiful iris and come to stay.

A CORNER OF MESSRS. BUNYARD'S COLLECTION OF IRISES.

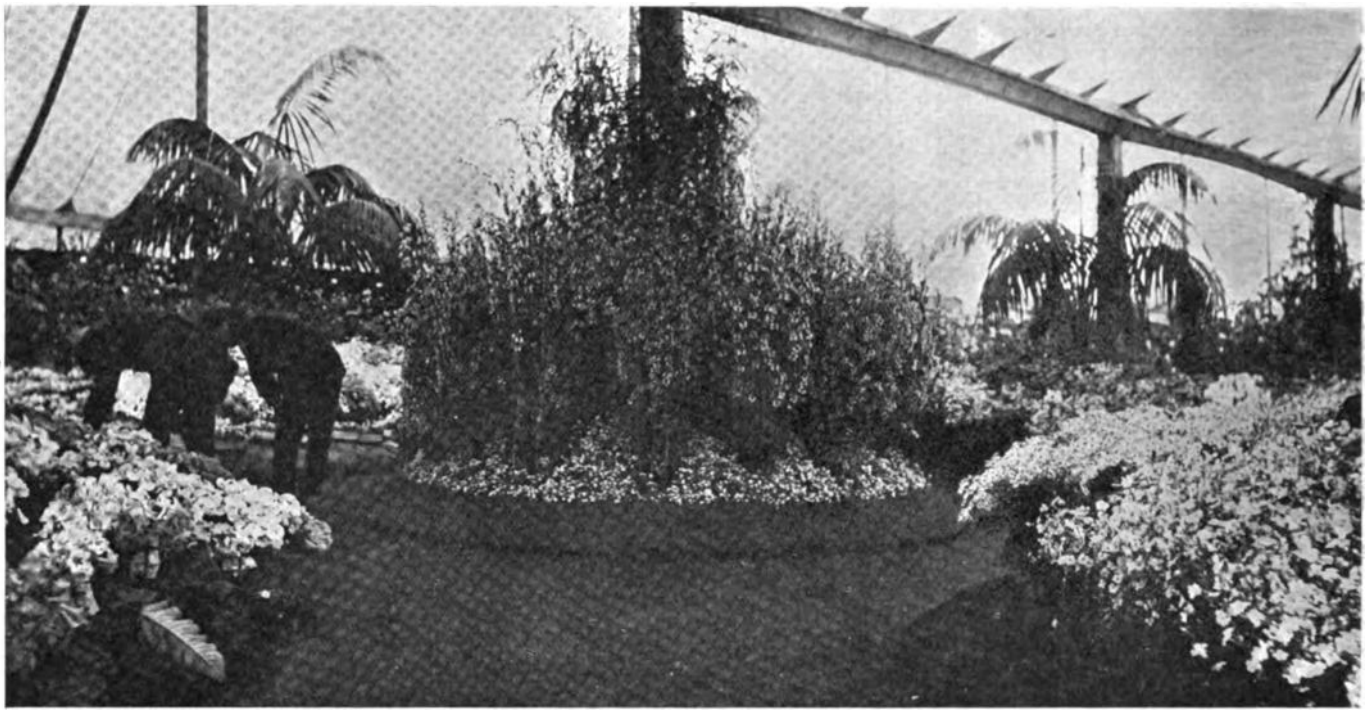


IRISES AND FERNS AS SHOWN BY MR. PERRY.

ANNUALS.

The plant of annual growth still retains its popularity with the public in spite of the greatly increased interest taken in herbaceous, bulbous and deciduous plants which form special features in so many gardens nowadays. Annuals have all the promise of simple and expeditious gardening; the harvest follows so easily, so surely, and so early is the flowering time compared to the date of sowing. By their aid the front garden can be made tidy and quite respectably furnished with little outlay and without interfering too much with week-ends, golf scores and holidays. But with annuals, as with all other flowers, it is more difficult to cultivate them in perfection than in a slipshod fashion, and all too often, from lack of a little more care and a little more knowledge, the results fall woefully short of the mental picture conjured up when the seeds were bought. If you would grow annuals well you have a splendid example of the *fait accompli* here to hand. An exhibit such as that displayed by Messrs. Sutton and Sons or by Messrs. Carter and Co. is worth a great deal more to the intelligent gardener than the mere regaling of the eye with pleasing colours. Note the plants themselves, how sturdy, bushy and well grown they are, and you will learn with a judicious question or two the real secret of successful results. With so much of the Colonial and American element about this year, Messrs. Sutton's exhibit is such as to make one proud of British horticulture. The centre-piece is built high with salmon clarkias, carpeted with white alyssum. Surrounding this are numerous beds laid out with tasteful colour schemes ranging from cool whites and blues of Cineraria stellata to the most intense orange-scarlet of Clerodendron fallax. Here, too, are salpiglossis as they can and ought to be grown, and among them one notices a new shade of soft purple-mauve and another of pure Indian yellow. Nemesias with which the name of Sutton is particularly identified, make glorious masses of white, orange and crimson; while the manner of

Digitized by Google



MESSRS. SUTTON'S FINE EXHIBIT.

displaying salpiglossis and Nicotiana affinis over carpets of Phlox Drummondii is extremely pleasing and effective. Tall and dwarf lobelias are also cunningly blended in the sixty beds comprising this unique picture of gardening. The employment of palms placed at intervals adds importance and grandeur to what is the most beautiful effort we have seen produced by the famous Reading firm.

Messrs. Carter and Co. have another splendid floor piece centred also with clarkias in rose shades and surrounded with schizanthus in rose and white. Salpiglossis in velvety garb are also strongly represented here, but the main features comprise a great range of greenhouse plants and will be dealt with in our next issue.

Messrs. Dobbie and Co., thorough in all they attempt, make many claims on the attention of the visitor. Their gorgeous array of May-flowering tulips will be described in detail next week, has an effective crescent edging of rose schizanthus and white Brompton Stock Snowdrift.

Like the Chelsea Show of 1922, this is another year of schizanthus, and one might travel far before seeing such splendidly grown plants of these showy annuals as are staged by Mr. Alfred Dawkins and Messrs. Hurst and Son; while the same flowers are also utilised largely, with linaria and Dimorphotheca aurantiaca, by Messrs. Webb.

SWEET PEAS

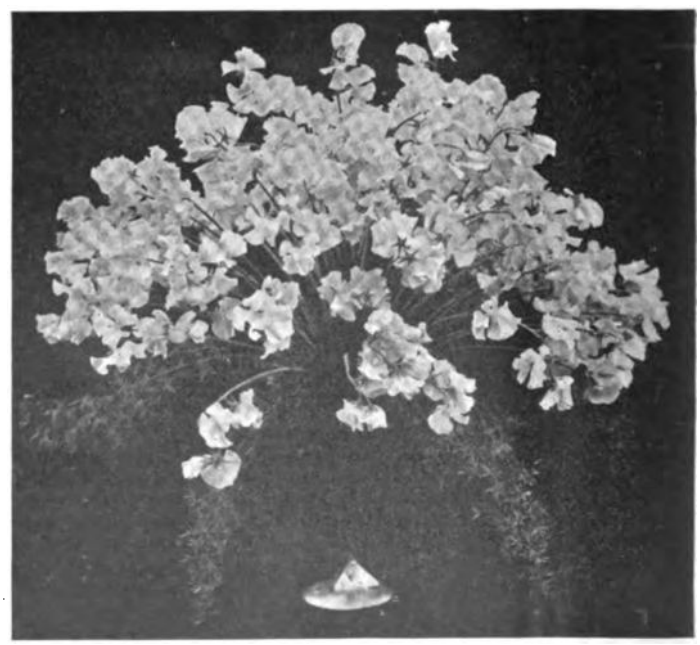
Year after year the last word seems to have been spoken about the development of this favourite summer flower, but year after year new things come to make us wonder and admire, and if one were confined to the growing of novelties as shown at Chelsea, there would still be a great range of colour in the garden.

In Messrs. Bolton's stand we note fine new varieties which will give great pleasure to all who love the queen of annual plants—and the names are as up-to-date as the blooms. Wembley and Empire are both reminiscent of the current year, the former a lovely soft pale bluish lavender, the latter a pale rose pink, both of them being new sorts of great merit. Angele has pinkish lavender wings and mauve standards, the colours blending well and forming a flower both striking and beautiful. Mammoth is a very rich orange, and Supreme is a first-rate decorator in its dainty satin pink. Wizard, one of Bolton's new ones of last year, is still outstanding in its unique shade of coral orange, and all the flowers shown on this stand reach a very high level of excellence.

Mr. Stevenson brings Coraline, a brilliant orange cerise, and Venus, pale salmon-pink on cream ground, which are quite new; and his older varieties, notable for lovely colouring, are Wild Rose, orange-pink shaded with old rose; Grandeur, rosy purple; Felicity, flushed pink on a white ground and Fair Lady, delicate pink on cream. This grower has two very fine peas classed among the so-called blues—Diana, a lavender-mauve, and Cynthia, a pale mauve. There is no background to assist the flowers here, but Mr. Stevenson needs little to set off the excellence of his culture.

From Messrs. Dobbie and Co. one looks for the finest that good culture can do, and there is nothing to disappoint in the display made by the Scottish firm. Naturally, the novelties for 1925 will attract much attention, and among them is one of distinct colour, viz., the cerise-rose of Rose Maiden. That well known variety, Royal Scot, is now surpassed by Grenadier, more fiery than the older one and better in form and substance. Ruby will also be hailed as a new colour in sweet peas—ruby-carmine seems to describe it, and not only is the shade a striking one but the plant is a fine grower and the form and placement on the spike all that fastidiousness demands. A new American variety strikes us as being the finest we have seen of the picotee-edged class, Youth by name, and it certainly has all the freshness of adolescence about it. The elusive yellow seems to be just a trifle nearer accomplishment in Majestic, which has a suspicion of sulphur on the cream petals.

Messrs. A. Dickson and Sons have a splendid lot of Hawlmark sweet peas most tastefully arranged in large baskets, the colours being thrown up clearly on a background of green formed by sprays of Asparagus plumosum. For next year this firm has three highly meritorious novelties, Pink Perfection, Blue Bird and Flambeau, all



MESSRS. BOLTON'S NEW SWEET PEA "WEMBLEY."

Digitized by Google

of them self-descriptive; but Blue Bird seems to demand special mention, as it is probably the finest of this colour yet raised. Other baskets that will catch the eye are filled with Purple Perfection, Lucifer, rosy cerise; Fairy Queen, flushed rose on cream ground; and Matchless and Champagne, two fine deep cream sorts.

The struggle to obtain something like a yellow pea is waxing keen again, and in Messrs. Ireland and Hitchcock's collection we note Mme. Sarah Grand, one of the prettiest of this section in deep ivory and cream. This firm has just secured the first F.C.C. granted by Covent Garden's newly formed Floral Committee for a new sweet pea called The Beacon—an appropriate name, one would say, for a flower with orange and coral blended together, forming an upstanding bloom of great substance with erect standard. Note here, too, another pair of lovely "blues"—Lord Lascelles, pale mauve, and Moonbeam, mauve and heliotrope; and, among the varieties already known, Annie Ireland, Bunty, Hawlmark Pink Improved, and Mascott's White, the last very pure in tone.

Messrs. Sutton and Sons make a brave show of sweet peas of daintiest and freshest colour tones from which we singled out a new seedling called Shell Pink, very exquisite as a vase flower. Where excellence is maintained at such a high level throughout, it is difficult to point out special vases for particular mention, but very beautiful indeed are Butterfly Spencer (another new one), Colne Valley and Tom Jones in strong shades of mauve, also Powerscourt of like colour, Gloriosa, Tangerine Improved and Blackseeded Cream. Several unnamed seedlings in this group may be heard of later on.

The Preston Hall Nurseries stage some choice varieties also.

CARNATIONS

With one exception the greenhouse carnations are shown by the trade growers, but the welcome exception is the Hon. George Herbert, who, from his gardens at Knoyle House, Salisbury, has sent a collection which is necessarily smaller than the others, but is quite their equal in quality. The principal sorts so well displayed are Enchantress, Nigger, Benora, Harvester, Mary Allwood and Astral.

A very delightful style of arrangement has been adopted by Messrs. Allwood Brothers, who have displayed a very dainty touch, though they show a large quantity of excellent blooms. From lightly arranged vases of yellow and pink sorts are suspended elegant baskets of dark crimson blooms. Jessie Allwood and Mary Allwood are associated with Triumph, while from Maine Sunshine and Wivelsfield Fancy spring Wivelsfield Claret. Of the many other varieties, Coral Glow, a richly coloured orange fancy, Topsy, Benora and Mikado insist on being admired.

At the Embankment end of the large tent, Mr. C. Engelmann displays an enormous quantity of excellent blooms. Very large stands, containing almost countless numbers, have Peerless, a glowing mass of rosy cerise, Saffron of rich yellow, and Cream Saffron, which is saved from insipidity by a delightful suggestion of the palest blush pink; Enchantress Supreme, of charming soft pink colour; Topsy, dazzling crimson; and White Enchantress. Smaller, but really large, stands contain Mrs. Hamilton Fellowes, rosy purple; Orange Sunstar, the scarlet Tarzan, and Sheila Greer.

On a table space Messrs. Keith Luxford and Co. are showing Tangerine, a beautiful fancy carnation; Coquette, a mauve-cerise fancy; and Lady Meyer, a very large mid pink; with such older sorts as Cheerful, Aviator, Bona and Saffron.

Adjoining their miscellaneous greenhouse plants, Messrs. Stuart Low and Co. have vases of White Pearl, Arnos Grove, of mauve and heliotrope colouring; Lady Inverforth, deep salmon; Eileen Low, pale salmon; Topsy, scarlet; and Red Ensign. Next to these they have splendid vases of the new roses, America and Roselandia, which we admired recently at Vincent Square.

Although, generally, the border carnation season is not yet, Mr. James Douglas is able to set up a large number of his splendid blooms. The fancies are especially good, and include Lieut. Shackleton, Lomond Hills, Viceroy and Highland Mary. The production of fragrant varieties has long claimed Mr. Douglas' attention and energies, so that he now has many varieties of delicious perfume. Of those now on view the chief are Wonder Clove, Sir Bonetto, Steerforth, White Clove, Purple Clove, Rose Clove and Blush Clove. Rather a new shade of colour in border carnations is apricot, which is represented by Melaine, a really charming flower.

At the time of taking these notes there was no definite information available, but we believe a collection of border carnations in another part of the tent belongs to Mr. F. W. Seymour. This includes such desirable varieties as Gondolier, Sam Weller, Cleopatra, Highland Mary and Lieut. Shackleton.

A PORTION OF MESSRS. DOBBIE'S EXHIBIT OF SWEET PEAS.

LILIES

One of the firms always associated in the gardener's mind with the lily is that of Messrs. Wallace. It is seldom, however, that they have matters quite so much their own way at Chelsea with this grandest of flowers as on the present occasion. Barring a few longiflorums here and there in miscellaneous exhibits, they have a monopoly. Their lily garden, if smaller than last year (to make room for an iris grove), is equally as interesting as that memorable display and is unlikely to be missed by any visitor. The Martagon section is well represented, bold groups of three Sutton Court hybrids being shown, these being Mrs. R. O. Backhouse, Sutton Court and Sceptre. The last named, probably the least known, we think the most attractive as shown, but all these gold or apricot and black "Turks-caps" are attractive. A very good colour form of L. Martagon is there, as well as the glorious Martagon album, while the buttery "Marhan" form, Ellen Willmott, will attract attention as well as Hansoni itself.

Lilium regale upholds its royal style and a group of sulphur-gale forms shows the variability of the sulphureum-regale cross. L. excelsum (testaceum) lifts high its nankeen blossoms, while a group of the grand old orange lily, L. croceum is the first shown at Chelsea for many years. Lovers of the rare and dainty will find a plant of Farreri and one or two other varieties—some, alas! only in bud; and many forms of L. umbellatum make bold splashes of colour. Orange Queen is a particularly good one, but grandiflora and the less known lingulata are even more showy.

Groups of hardy cypripediums and Roscoea cautleoides lend variety and Japanese maples and that most beautiful of hardy ferns, Adiantum pedatum give needful foliage colour. The mauve Ixiolirion Pallasii, shown here in quantity is perhaps "liliaceous" enough to justify a mention.

CLEMATISES

Quite one of the features of the Show is Messrs. Geo. Jackman and Sons' exhibit of large-flowered clematises. This firm, whose name is a household word for clematises, has on this occasion surpassed itself. Almost every large-flowered variety in commerce is on view, and that in excellent form, and it seems almost invidious to mention names; but the huge blossoms of Gloire de St. Julien (lilac), Marie Boisselot (pure white) and Fairy Queen (blush pink), though these are less free to flower than some of more reasonable dimensions, compel attention. The striking bi-coloured blossom, too, of the always popular Nelly Moser stand out from the cooler tones of lilac and purple and the glistening whites. It is a little unfortunate that this splendid group should have to compete with the multi-coloured splendour of Mr. Jones's hydrangeas.

HARDY FLOWERS.

A lovely group of delphiniums is shown in tent No. 1 by Messrs. Blackmore and Langdon. Noble and stately spikes of the better kinds are shown at their best, including such sorts as Princess Mary, pale blue and mauve; Marjorie Ferguson, pale blue; Lavada, deep mauve; George Cochrane, deep mauve-blue; Rev. E. Lascelles, deep blue and white double; Glory, palest mauve; Mrs. Colin McIver, lovely rich mauve; Purple King, deepest mauve; Blue Boy, single blue; Turquoise, semi-double bright blue; and Millicent Blackmore, mauve and blue, a beautiful double sort. It is quite impossible to mention but a tithe of the grand things in this group.

A magnificent lot of hardy flowers is seen in a large beautifully arranged group set up by Messrs. John Waterer, Sons and Crisp. Here are displayed in delightful fashion Lupinus polyphyllus, LL. Delight, Pink Pearl, Fascination, Sunshine and many of the older varieties of this plant. There are also delphiniums, irises, aquilegias, peonies, eremuri, heucheras and other beautiful hardy flowers, all charmingly disposed. This exhibit is to be seen at the Embankment entrance of No. 2 Tent.

A triangular group of trolliuses, Iceland poppies, Oriental poppies and other such plants make an attractive show in No. 2 Tent, as exhibited by Messrs. Wm. Artindale and Son. The most noteworthy examples being Trollius Helios, TT. Orange Globe, Lichtball, Golden Wonder, Goldquelle and europæus. Ranunculus aconitifolius fl. pl. and other plants make a beautiful floral picture.

A lovely circular group in the same tent, arranged by Messrs. Geo. Jackman and Son, comprises lupins in charming variety, irises, delphinums, lavateras, aquilegias, kniphofias, cytisuses, cheiranthuses and a host of most beautiful plants that everyone wants in their garden. Surrounded with Acer Negundo and palms, this is a most attractive exhibit.

Messrs. B. Ladhams, are showing a lot of beautiful plants in a table group in Tent No. 2. There are several plants worthy of notice, such as Thalictrum Purple Cloud, Polemonium carneum, Heuchera Pink Pearl, Mimulus luteus (semi-duplex), Heuchera tiarilloides, Primula japonica "Etna," Cheiranthus Little Gem, Achillea montana, Geum rivale (Ladham's variety), G. Borisi, Aster alpinus, King Viola gracilis in variety and many other pretty plants.

Messrs. Storrie and Storrie, have a very showy table group of hardy primulas, polyanthuses, border alpine auriculas, set up in the admirable manner peculiar to this firm. Aquilegias are very good in this instance, charming colours being represented in all of them. Scotland Yet, is a fine thing, scarlet and yellow petal. England's Glory is also a lovely variety, blush pink and yellow. Among the alpine auriculas in blue and helio shades are many very beautiful things, and there are also others in yellow and cream shades. The border polyanthuses and cowslips in charming variety, have much to commend them.

A few bunches of hardy flowers are shown together with alpine plants by Mr. W. Wells, Junr. Lupinus Moerheimi, L. Merstham Gem, Trollius Orange Gem, Thalictrum aquilegifolium purpureum, Heuchera tiarelloides, Onosma taurica, double Pyrethrum Queen Mary, single Pyrethrum Hamlet, are a few of the more noteworthy plants in this group.

St. Brigid anemones, exhibited by Messrs. Reamsbottom and Co., are a most attractive table group in tent No. 2. The flowers are large, of brilliant colours and are set up mos attractively.

In the same tent Messrs. R. Gill and Son, make up a table group of anemones, blue bells, Lilium regale and flowering shrubs. The arrangement of the flowers might have been improved upon.

Messrs. Kelway and Son, show pyrethrums and lupins in pleasing variety. The new single pyrethrums worthy of note, Prince of Wales (carmine), Lady Astor (white tinted pink), King of Spain (bright crimson), Mrs. James Kelway (cerise pink with twisted florets). There are many other beautiful things, all worthy of attention.

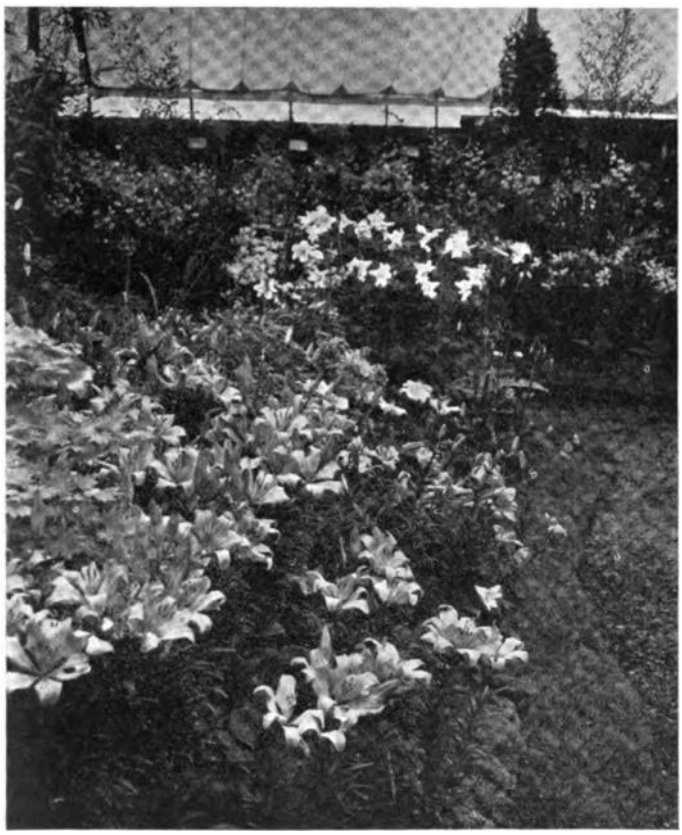
Mr. Fredk. G. Wood, has a small table group in No. 2 tent, comprising such things as Oriental poppies, heucheras, geums, campanulas and other plants, not arranged very satisfactorily.

Seedling varieties of Lupinus polyphyllus are shown in large numbers by Mr. G. R. Downer. There are many varieties shown under numbers, but others worthy of especila mention, such as The Dingle (pink), Bella Jones (violet), Mount Everest (white), Downer's Delight, Chelsea (mauve-blue), Goodwood (bright pink), May Queen (violet) and many others too numerous to mention.

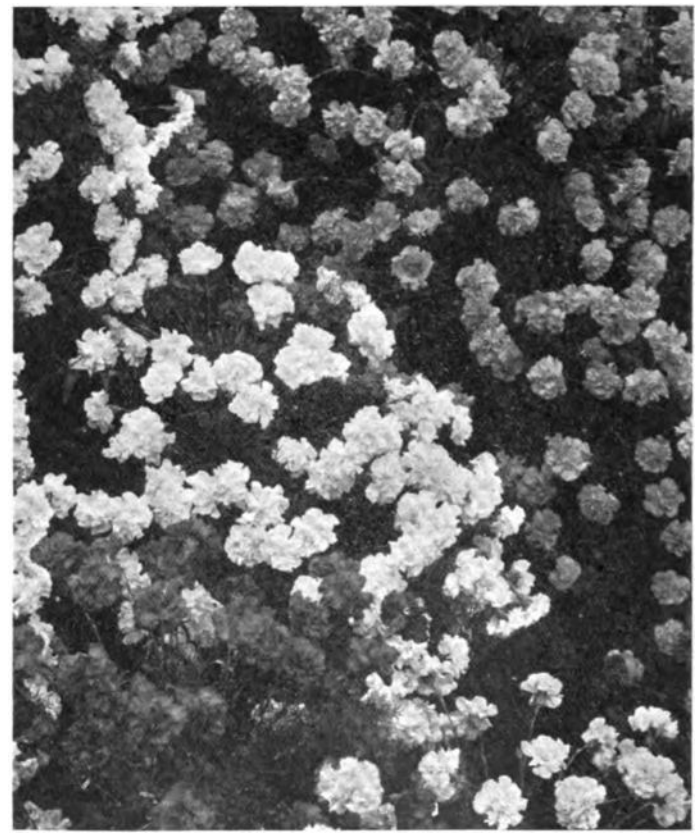
Mr. George G. Whitelegg, showed, in a group of iris, good bunches of Lupin Sunshine and Trolliuses Orange Globe and Phœbe.

A table group in No. 2 tent, exhibited by Mr. G. A. Miller, included a great variety of plants, such as polyanthuses, mimulus, single Pyrethrum Early Favourite (deep pink), Daphne Cneorum, heuchera, Genista præcox, lilacs, etc.

Lupins from Messrs. Godfrey and Son, are shown in bunches of unnamed sorts, and forms of Viola gracilis are also displayed. A sort of horseshoe border,



SOME OF MESSRS. WALLACE'S LILIES.



PERPETUAL-FLOWERING CARNATIONS SHOWN BY MR. ENGELMANN.

In next week's issue we shall publish detailed comments on Rock Plants and Primulas, Stove and Greenhouse Plants, Pinks and Alpwoodii, Orchids, etc., and Garden Sundries, with descriptions of New and Rare Plants.

Digitized by Google

SOME SHADE-LOVING ROCK PLANTS

DESCRIBED below are a few choice plants that require shady positions in the rock garden; positions which are not too easily furnished when only choice or rare plants are required. Some of the plants are difficult to make happy, even though a good deal of care and attention may be given them; but that is the most interesting and fascinating part of the hobby, and to triumph over the most difficult little plant gives unlimited pleasure. In odd cases, no doubt, the joy one may get in mastering a hard subject, exceeds the joy that the perfected plant grants one.

In Omphalodes Luciliæ, from Asia Minor, we have a perfect treasure, with many likes and dislikes, usually more of the latter than the former, when attempting to provide a home for it in the rock garden. However, it is an ardent lime-lover and appreciates a shady corner, cool and moist in summer. Quite an agreeable compost may be made up of two parts limestone chips and old mortar rubble and two parts leaf-mould, loam and sand. This should be placed in a suitable pocket with a due north aspect. The foliage of the plant, handsome in appearance, is of a blue-grey colour, and the forget-me-not-like flowers are a lovely electric blue, tinged with the faintest flush of lilac. The most successful means of propagation is by seed, which, curiously enough, should be taken from the plant and sown when the nutlets are still green.

Pyrola rotundifolia is a rare British native, belonging to the winter-green family, whose home is to be found in the cool shade of a woodland. It is evergreen, with round leathery leaves of deep green. It carries six to twelve waxy white flowers on a raceme about 9ins. high, and has a lily-of-the-valley-like appearance. The flowers are also deliciously fragrant. A shady corner filled with peat and leaf-mould will assist in making the plant at home, and when it is established it will soon make a handsome patch.

Unlike a great many of the wood sorrels, Oxalis enneaphylla from the Falkland Islands never makes itself a nuisance, although it is an easy doer generally and a plant of genuine merit. It favours shade, peat and leaf-mould, together with good drainage. It increases by multiplying its scaly corms into a compact tuft. Being deciduous, it disappears in autumn and reappears in spring, first producing its grey heavily-crinkled foliage, which is followed immediately by shining white flowers on 2in. stems. There is also a fine pink form, known as O. e. rosea, which requires exactly the same treatment. In each case the flowers are large and are convolvulus-shaped.

Cypripedium Calceolus is reputed to be the gem of British wild plants, although I believe it is now almost extinct in this country. Its beauty forces it to be placed in one of the choicest of choice corners, shady, cool and moist, with its roots in rich leaf-mould and loam, not forgetting an adequate supply of lime rubble. The foliage usually consists of four large, heavily veined leaves, and the flowers are generally borne singly, sometimes two, on a 6in. to 12in. stalk. The flowers are large and very attractive, having a pale yellow inflated pouch or bag and long purplish-chocolate petals.

Astilbe simplicifolia is a dainty baby "spiræa" with a graceful habit and possessed of a good constitution. There is no difficulty about growing this plant if it is provided with a moist and shady corner and a compost of fibrous loam and leaf-mould. Flowers are borne in June, comprising dainty feathery plumes 6ins. high, of a rich cream shade, from tufts of glossy green leaves, which turn to a reddish-brown tint in autumn.

One of the great favourites among alpine lovers is Ramondia pyrenaica. It requires deep shade, unless it is found convenient to plant it where it can have abundant moisture in summer. For instance, if it were possible to give it a crevice by the side of a waterfall, where it could be constantly sprayed in hot weather, then it might thrive in full sun; but otherwise, a northern exposure would suit it more. By planting it on its side in a crevice, the best results may be expected, provided that a good sound mixture of peat, leaf-mould and silver

OXALIS ENNEAPHYLLANEVER MAKES ITSELF A NUISANCE.

A FINE PLANT FOR A NORTHERN EXPOSURE, SHORTIA UNIFLORA GRANDIFLORA.

Digitized by Google

sand forms the root run. It makes large flat rosettes of crinkled hairy leaves of rather coarse texture, and in June or thereabouts it produces its lovely mauve, golden-eyed blossoms. There are two other rarer forms, known as R. p. alba and R. p. rosea.

For a shady corner or for carpeting under trees, preferably pines, Linnæa borealis, a rare native of Britain, is excellent. It makes long trails of growth, with small round leaves, set out in pairs. From the axils of these arise the flowers, which are also in pairs. They are poised on slender 1in. stems, hanging gracefully, like waxy pink bells and are sweetly fragrant. Peat, leaf-mould and decayed pine needles make quite a good compost. It is evergreen, and if the trails are pegged down they will root freely.

Shortia uniflora grandiflora is another fine plant for a northern exposure, with handsome reddish foliage, stout and tough, which contrasts greatly with the large, nodding, delicate pink flowers, that resemble heavily fringed open bells. As the second name suggests, they are borne singly, on 3in. or 4in. stems. Good drainage is essential and a deep pocket of the best peat and silver sand.

THE SHADE-LOVING RAMONDIA PYRENAICA.

Patrinia palmata is a pretty shade plant, but is only too uncommon, as it is a perfectly easy doer without being made any fuss of. It will flourish in any good loam and leaf-mould. Its bright golden yellow flowers are borne in corymbs about 4ins. high and the foliage forms a tuft of bright green palmate leaves.

Primula Loczii is a lovely species of fairly recent introduction from Tibet. The heads of pink flowers are very similar to those of Primula frondosa, save for the farina which is absent in P. Loczii; thus somewhat resembling the species of the sibirica clan. The leaves are of a pale, often yellowish green. The chief characteristic of the plant is that it throws out runners several inches in length, and these terminate in a rosette of leaves. Roots will soon be produced if a little soil is placed over the runner, which may then be detached as a separate plant. Leaf-mould and silver sand, in a roomy pocket in cool shade, seem to be the limit of its requirements.

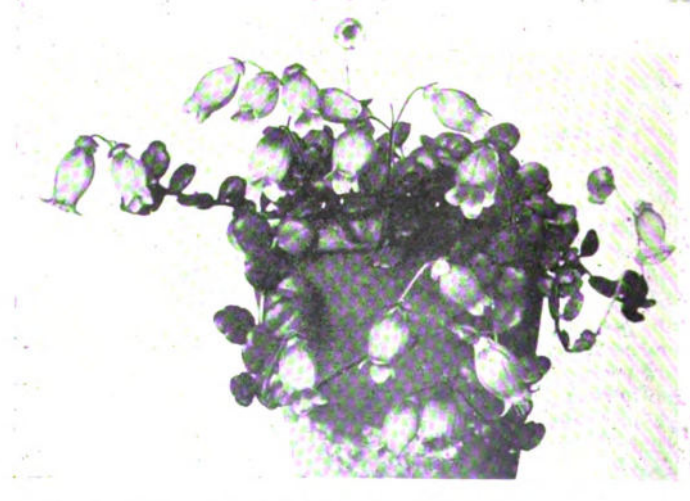
F. BARKER.

AN IDEAL PLANT FOR A COOL HOUSE

A VERY beautiful plant with a very cumbersome name, Kitchingia uniflora is comparatively new, having been introduced only some fifteen or twenty years ago. Its home is supposed to be the island of Madagascar, where all the members of this genus of Crassulaceæ come from. For some reason—its name, perhaps—the plant is still quite a rare one in gardens, which is a great pity, for it is certainly quite worth growing. The slender, slow-growing stems, carrying small fleshy rounded leaves, creep along the ground or hang down graciously when in a position to do so. They keep sending down roots at the nodes as they crawl forward. In the spring, or at other seasons of the year, according to culture, they send up quantities of graceful little bells of the most lovely pink.

It has the added advantage of lasting a long time in flower. As the specific name implies, the flowers ought to be single on each stem, but since the plant was named by Dr. Stapf in the *Kew Bulletin* for 1908, it seems to have taken a most malignant pleasure in sending up two or even three at a time on each stem.

The photograph here reproduced gives some idea of what the plant looks like when in flower, but the colour of the bells, which is everything, is, unfortunately, lacking. Owing to the climate of the country of origin, Kitchingia uniflora requires a temperate or a cool greenhouse treatment when cultivated in northern Europe. The best way to grow it is, probably, to keep it in a temperate house in winter under moderately dry conditions, and to give it, in summer, cool greenhouse quarters with more moisture. Small pots, or pans, well furnished and in full flower, make delightful decorative subjects. Propagation is easy, for, as has been stated, the stems root naturally as they develop or will root readily as cuttings.



THE GRACEFUL PINK BELLS OF KITCHINGIA UNIFLORA.

C. L.

ALPINES ON THE MONTE MORO PASS

(*Continued from page 352.*)

A LITTLE lower still, Chrysanthemum alpinum, extremely pretty, took its place, also in mats of lovely foliage plentifully relieved with its dainty white daisy flowers. Lloydia serotina was seen locally in masses at about the same level. Silene acaulis exscarpa was much finer and flowering more freely on this side of the pass. At about 7,000ft. Senecio uniflorus with its silvery serrated leaves and fine single short-stemmed golden daisy flowers was a pleasing feature in a greensward jewelled with many other notable alpines, including Senecio incanus. Seedlings of both these senecios were obtained in the Alps some three years ago and planted on my little moraine. S. uniflorus lingered on until last summer, S. incanus dying out in its second year, neither of them flowering. The trouble seems to be the frosts and thaws that we have in our winters so frequently loosening and lifting out the roots, and the damp days also encourage rot if the plants are not protected. Silvery squat artemisias were frequent, the "Genepi" of the Swiss. Reginald Farrer in his "English Rock Garden," draws attention to the value of this plant to strayed travellers, stating that "a few of the leaves, bruised and nibbled, will bring back vigour to the most weary; and no traveller or climber, if he only knew, need feel his sinews or his heart give out, in even the most awful stony wilderness of the upmost Alps, so long as the silver leaves of any mountain wormwood are heaped about on the shingles beneath his aching feet." Alfred Wills (Justice Wills) one of the brilliant group of British alpine pioneers and writers in the middle of last century, in his "Wanderings among the High Alps," calls attention to another high alpine plant of use in time of need: "Reindeer Moss (lichen Rangiferinus) . . . A small bit of this plant, carried in the mouth and sucked, is one of the best things to allay thirst or stay hunger, when on a mountain excursion. It is slightly bitter, but not unpleasantly so, and very nutritious and fortificant."

On these high pastures there are tiny rosettes in quantity of a primula which must be a form of P. hirsuta. I should have been inclined to name it P. minima if all the books at my disposal were not so emphatic on this primula not being a native of Switzerland; unfortunately, it was out of flower, but some dead flowers that I saw seemed to have been single and almost stemless. A few rosettes were crammed into a tobacco tin; a good many of these are now quite fresh in a sand frame and I can only hope that they will flower and solve the problem. A dwarf form of Antennaria dioica was also here with reddish flowers, and tiny rosettes very similar to some taken in the higher parts of a Yorkshire locality. Antennaria carpatica was seen at a lower level—the leaves of this plant seem to lose their "hairiness" when planted in the garden. Continuing on towards Mattmark, Campanula excisa was a pleasant feature, generally in the more stony places. This local campanula, with its quaint deeply cut and perforated petals, was luxuriously abundant and continued for many miles down the Saasthal, but was much less common at the lower levels. This campanula planted in 1915 continues to run about and flower (as well as the slugs will allow) in my little moraine bed. A large purple rotundifolia belled campanula with single flowers beautifully poised on 3in. to 4in. stems was gloriously beautiful in a limited area. I have also seen a similar campanula in one or two other localities including Zermatt and with flowers of pale silvery blue as well as purple. It would be a gem for the alpine garden if it would only flower in the same way. I imagine it will not, at least I have never had the pleasure of seeing it, nor even seen it illustrated or named to recognise. It is possibly the campanula referred to by Mr. Clarence Elliott in his interesting note in THE GARDEN recently on Campanula linifolia of Mont Cenis meadows; but it is not at all the same as the latter, which in the luxurious meadows in which it occurred had to be at least 2ft. high to show itself. Reginald Farrer's reference in "Among the Hills" is as follows: "In the lush herbage in the hay fields around . . . there were now campanulas in swathes and sheaves, linifolia like a giant violet Harebell and rhomboidalis in luxuriant bending jungles." Mr. Stuart Thompson's reference to a hybrid between C. rotundifolia and C. rhomboidalis is worth following up, as it certainly had the more upright carriage of C. rhomboidalis with purplish rotundifolia-like flowers, larger and fewer in number than typical C. rotundifolia.

As it was getting late, owing to my "hold-up" on the top, I decided to stay the night at the little inn at Mattmark See instead of going on to Saas Fee as intended. Some interesting plants are to be found by the side of this interesting glacier lake at the edge of the Allelein Glacier one end of which reaches right up to the track. A very pretty cotton grass, Eriophorum Scheuchzeri, with its large white fluffy heads, was prominent in the marshy ground by the lake side, as was the dainty Pinguicula alpina in boggy places. I also noticed Astrantia minor, also Campanula spicata, but with poor flower spikes in comparison with those seen at Mont Cenis. Campanula pusilla was frequent all down the Saasthal. Campanula barbata had its silky bells finer and more variable than on the Italian side, including pure white and pale silvery blue flowers. Myosotis alpestris was not common on the route, although on a previous visit to this district it was very fine in restricted localities higher up. Gentiana acaulis was in seed and the large purple flower heads of Gentiana purpurea were particularly noticeable. Anemone alpina and A. vernalis with their fluffy seed heads and Bupleurum ranunculoides (Hare's Ear) were also on the Gletscher Alp. Two other species of this occur in the district but were not seen. Sedum dasyphyllum, S. grandiflorum and S. Rhodiola (rosea) were noticeable, and in wet boggy places S. villosum was found along with fine green rosettes of Saxifraga stellaris and Bartsia alpina. The latter association reminds me of a similar one in the springs and streamlets of the upper part of Mickle Fell, Yorkshire's highest mountain, where S. villosum with its beautiful rose pink flowers and the dainty white stars of S. stellaris were particularly beautiful when seen on a miserable drizzly day in August of the previous year while seeking for S. hirculus.

After a comfortable night a fairly early start was made for Saas Fee, where a few hours were spent. On leaving Mattmark and passing by the end of the glacier the track is somewhat shut in by high mountain walls until it opens out and brings into view the magnificent amphitheatre above Saas Fee, formed of Switzerland's highest peaks, including The Dom, the highest actually in Switzerland, the Taschhorn, the Alphubel and the Allalinhorn, together with some of the finest glaciers in the whole of the Alps. The climb up from the valley is steep and somewhat trying in a hot sun. Dianthus sylvestris and D. Carthusianorum were pretty frequent by this path and more or less frequent, especially the latter, down the remaining part of the Saasthal to Stalden. D. Carthusianorum seems to take the place of D. neglectus (of the Italian side) on this side of the Alps and is common in stony parts of the pastures and by the wayside.

After lunch the track was taken by the lower part of the Fee glacier, with torrents from the melting snow dashing down its deep cut tracks, to the alpine pasture of the Gletscher Alp, a pasture almost surrounded by the glacier and famous for its alpine flora. Unfortunately it had been "eaten" off pretty well by cattle, but still many interesting plants were to be seen, although not in the masses of an earlier period. Colchicum alpinum was just nicely coming into flower in the well watered meadows; it is quite a beautiful feature of the meadows here and also at Zermatt. Primula hirsuta was frequent in shady places and rock crevices both on the way to the Gletscher Alp and in the valley towards Stalden. On the high pastures Gentiana utriculosa was very fine with its pretty clustered blue flowers; unfortunately it is only biennial. Androsace obtusifolia was seen sparingly and also Saxifraga obtusifolia. Aster alpinus was fine locally, along with the rich orange daisy flowers of Arnica montana and occasionally Geum montanum. In the early evening my journey was continued down the Saasthal to Stalden where I arrived considerably after darkness had set in and stayed the night, previous to my passing away from the joys of the Alps into the more usual worries of everyday life.

MULCHES AND MULCHING

I AM greatly surprised that more use has not been made of mulches up to now in the average garden. The process of mulching is probably as old as the hills, as references to it are made in early garden literature under various names. It may be that gardeners are not aware of the advantages which accrue from carrying it out, which advantages are very real indeed in these expensive and somewhat difficult horticultural days.

One of the most important advantages of mulching is that it reduces the need of watering, and consequently the cost of labour in working the garden. It also reduces the amount of surface cultivation, such as hoeing, hand weeding, stirring with the cultivator, and raking, as, if mulches are not applied, one has to be constantly attending to these other jobs. Another advantage is that it keeps the roots of one's plants cool, which is a different thing entirely from keeping them moist. If the roots of flowers and vegetables are kept reasonably cool in hot weather, growth appears to be definitely stimulated, whereas if the roots get hot, with very few exceptions, the speed of growth is reduced, as the plants become torpid and lazy, like many of us do when we go to relaxing seaside places for our holidays.

There is a further advantage of mulching against non-mulching, and this is that the mulch, in a mild way, may serve to stimulate the growth of crops by the feeding materials it contains. This, of course, is only in evidence when the mulch is of rich material, or, in other words, when top-dressing is combined with mulching. I usually regard the two as distinct, since a mulch will be exceedingly useful and effective if it is of some comparatively poor material, such as lawn mowings, the stimulating effect of which, even when watered through almost daily, is practically nil.

Mulches are divided, then, into two great groups, those which are rich, and those which are poor. From this it almost follows that the first are apt to be extravagant, and the second are almost invariably the more economical. A mulch which is practically a top-dressing of rich manure is very rarely required in practice, and hence I think the process has got a bad name in certain districts. I have often heard it said that mulching is exceedingly extravagant, and so it is if one has to use farmyard manure for it. I do not think, if farmyard manure and nothing else is used, that the process can ever pay for itself in these days, when dung is so expensive.

Let us take the rich group of mulches first. These consist, as I have already said, of farmyard manure, but stable manure and cow manure are also used. Sheep manure and pig manure I do not recommend for mulching, for obvious reasons. It may be mentioned that farmyard manure may usefully be employed as a mulch on any kind of soil, but that stable manure is better for the heavier loams, while cow dung is of very great use on the lighter land. It is an important point to avoid applying these manures in an absolutely fresh state, and half-rotted farmyard manure or stable manure should invariably be employed. Old hot-bed manure, while very useful, is hardly ever available as a mulch, since it almost always goes straight to the potting shed to be made into potting soil. With regard to cow manure, if this is used as a mulch in a fresh state it is, of course, exceedingly difficult to spread, and shortly after spreading a hard skin will form on the surface which will throw off any rain which falls, instead of absorbing it like a sponge, and rob the roots of moisture when they most require it. Cow manure should be stacked long enough in a heap before being used as a mulch to get over this skinning stage, and the time required for this varies considerably with the nature of the weather. As long as it spreads like paste or pudding, it is not yet ready for use as a mulch.

With regard to the other class of mulching materials, *i.e.*, those which are poor or comparatively so, quite a number of materials has been used. Lawn mowings are very valuable; half-rotted leaves are exceedingly so; peat in a half-dried state is quite good, although this is generally used more as a top-dressing than as a mulch; well rotted vegetable manure, *i.e.*, decomposed weeds and plant remains, is quite useful; but pond mud is utterly objectionable in any condition.

As regards lawn mowings, I know that they are very often used as a mulch in a fresh state both for flowers and vegetables, a layer about an inch in thickness being put along both sides of the rows of such plants as culinary and sweet peas. Such mulches have to be renewed at very frequent intervals if the weather is really hot, since the mowings dwindle down or evaporate practically to nothing. If, however, the mowings are treated before being applied, the mulches will remain much more lasting, and it is a good plan to throw the mowings into a heap, mixing about a spadeful of soil with every boxful from the mower, and allow them to warm up for a day or two and turn yellow or brown. There will, of course, be loss of bulk as a result of this heating, but the mulch when applied will last much longer. No special treatment is required before using any of the other materials except in the case of vegetable manure. Care should be taken if this is to be applied to see that the decomposition has gone far enough. If any of the weeds have not been completely killed by the process, growth will restart as soon as these are spread out in a layer along the rows of plants in the open air. If, however, the bottom portions of the manure pit are used, there is very little danger of trouble being experienced in this direction.

It is necessary now, before concluding, to give a few hints on the actual application of mulches, as I have frequently known gardeners defeat their own object when the materials were excellent both in kind and quality. The object of the mulch is, primarily, to conserve the moisture in the soil; but in applying this conserving material one covers up the soil and therefore protects it from any rain which falls, which, of course, first-class mulches absorb. If the mulch, therefore, is applied when the soil is dry, it follows that the plants' roots will be kept in a dry condition, although they will be cool, and very unsatisfactory growth will be the result. Mulches, therefore, should only be applied when the soil is in a moist state.

It is, however, often impossible to get the mulches ready, however early one starts, before the soil becomes thoroughly dry. Many gardeners, of course, do not think about mulching at all until July, and at that time the soil may have become dried through to a very considerable depth. My object in making these comments on mulches early in the summer is that the materials shall be applied before the ground has been completely robbed of its moisture. Where, however, the ground is light and sandy or the operation has to be postponed for various reasons, such drying-up will inevitably take place, and before material of any kind is applied this moisture will have to be made up, otherwise it is far better to leave the operation entirely alone. One thorough soaking with the hose-pipe, however, will do all that is necessary, and immediately this is completed pack the mulches on at once. Any subsequent watering is generally done through the mulches.

The thickness of the mulch varies very greatly with the kind of soil, the kind of crop, and the kind of material. I am in favour of a fairly thick layer in the first instance, since loss of bulk is almost certain to take place, however carefully the material may have been prepared. Some of the stronger-growing vegetables appreciate very thick mulches, these being applied in a layer up to 3ins. or 4ins. on hot and light land. In most cases a mulch 2ins. in thickness will be ample, provided that the material is of a lasting character; but where unprepared or fresh lawn mowings are applied a 2in. mulch is frequently reduced to a mulch less than an inch in thickness by a couple of hot days, and hence, if the object in view is to be maintained, a very thick layer will be required in the first instance.

One last point. In the flower garden mulches certainly look rather ugly, but their appearance can be greatly improved if a very light sprinkling of fine soil is given immediately after applying them. I need hardly add that a mulch of peat should only be used in the shrubbery where rhododendrons are cultivated or other ericaceous shrubs are to be found, and that in the flower garden itself it should only be used for plants which like rather an acid soil, as some of the acid the peat contains is certain to be washed down to the roots after the first heavy rain.

E. T. ELLIS.

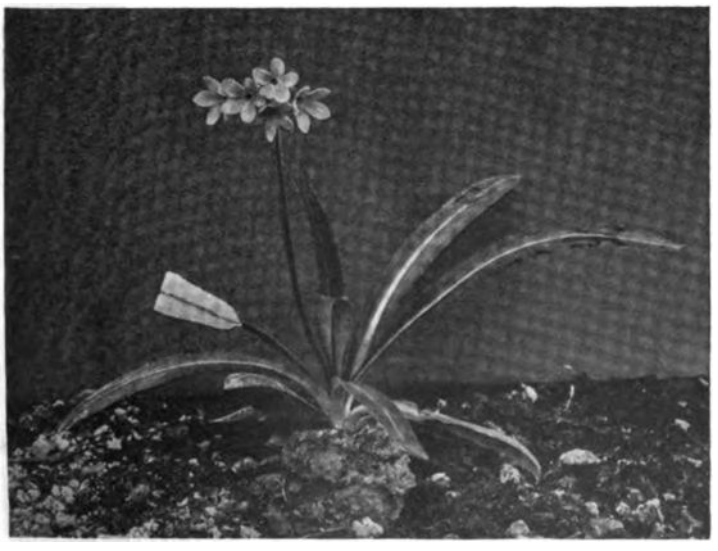
NOTES FROM CONTRIBUTORS

SOME PRIMULAS OF THE NIVALIS SECTION.

THE species included in the nivalis section contain some of the most beautiful of our early-flowering primulas. To the cultivator, up to the present, they have presented considerable difficulty; indeed, I know of no one who has been successful in finding suitable conditions in which they may be kept in health over any number of consecutive years. Most are easily raised and grown to the first year of flowering, but the second winter usually finds them in a weakly condition from which no amount of attention will induce them to become vigorous again. Here we have lately experimented with most of the species in cultivation around the edge of the pond, among the grass, not many inches above the pond level. This is the only place at all imitating the conditions of a wet meadow, and, so far, the plants appear to be strong and healthy. Among the first to flower are P. sino-purpurea and P. sino-plantaginea. Both are handsome plants from Yunnan, which are attractive both in foliage and flower. In the first the golden meal is conspicuous on all its parts, especially on the lower surface of its broad leaves. It flowers in April or May, the inflorescence rising above the foliage, bearing numerous lilac purple flowers the eye of which is greyish white. The last named is a nearly allied plant with slightly narrower foliage and less deeply coloured meal, with flowers of a deeper purple tint. The illustrations of these show them in their first season of bloom. Another desirable species is P. calliantha, which we have raised here, but never yet been fortunate enough to coax it into flower. It has meal on its foliage of the deepest gold, and lavender flowers. If we could induce it to flower it would be a desirable addition.

Perhaps the least exacting of the species so far known in cultivation of these Chinese species is P. chionantha with white flowers and sturdy foliage covered with a light golden meal. This readily lends itself to cultivation, and I have seen plants in a garden on the borders of Perthshire which have flourished for at least four years in a well drained moist, loamy soil. Of the later additions there are several outstanding plants which have been introduced by Farrer, Forrest and Ward, several of which have been lately described by Professor Smith in the Notes of the Royal Botanic Garden. These are P. Agleniana, a robust grower with tall scapes of flower of a creamy yellow colour and fragrant. P. Coryana is another giant of this series described by Forrest as growing to 18ins. in height with fragrant rose lavender coloured flowers. In P. ingens we have a still stronger-growing species than the preceding, which is stated by Forrest in his Field Notes to be "the most robust as well as one of the most beautiful primulas I know," one of the fruiting specimens he collected being between 2ft. and 3ft. in height. It is much to be desired that these last may prove amenable to our climatic and cultural conditions. There can be no doubt of their beauty, and their colours being quite distinct from the Candelabra section, now so popular, they would be welcome additions to our gardens. There are other species of this section in cultivation, such as P. pulchella, a good blue-flowered plant, and its near ally, P. pulchelloides, with rather lighter flowers and longer foliage, as well as P. Prattii, a yellow counterpart of P. pulchella, but as far as our experience goes these have not proved altogether satisfactory out of doors, but succeed well in frames, and would make good plants for the alpine house.—R. L. HARROW, *R.B.G., Edinburgh.*



PRIMULA SINO-PLANTAGINEA. KINGDON WARD, NO. 4911.

TULIPS AT VINCENT SQUARE.

DISAPPOINTMENT and surprise. In these two words I sum up my feelings as regards tulips at the Royal Horticultural Society's Show on May 13th and 14th. The disappointment I half expected, for I felt quite half-sure that there could not be a sufficiency of bloom, even in the south, to fill the Schedule of the Royal National Tulip Society that Mr. Peters, the Secretary, had not very long since sent me from Cambridge. The florists' tulip may be a cultivated taste, but it can claim as one of its devotees a Queen of England. Queen Adelaide had a tulip bed at Windsor, and tradition asserts that Queen Victoria attended one, if not two, of the Society's shows. In my own small experience I can quote two involuntary ejaculations from men well known and honoured by horticulturists. George Gordon, editor of the old *Gardener's Magazine*, once pointed me to a "Trip to Stockport." "Well, after all, it is *uncommonly* beautiful"; and on another occasion when the Hall at Vincent Square was filled to overflowing with good things, I came upon Sir Frederick Moore looking at a "pan" of prize blooms. "Jacob, I don't know if these are not the most beautiful flowers here." I often wonder if any flower will have a more prominent position assigned to it in Paradise than the tulip. For countless years it has afforded much pleasure to "Turks, Infidels and Hereticks," to say nothing of good Christians. When all this is weighed in the balance, *where* will the flower be found that will weigh it down? I once went to a show—a pukka tulip show — at Wakefield, when in one class there were *eight* prizes. The first was eightpence and the eighth, a penny! No more could be afforded, but there was as much keenness to win a prize as there is to win one of the "big" cups at Chelsea, perhaps more, and

Photos: R.B.G., Edinburgh.

P. SINO-PURPUREA.

certainly as much gratification in the winning. If these English florists' tulips were absent, there were others of great interest shown by Mr. W. R. Dykes and representative of the other end of the scale, that is, "nature unadorned." There were six of them They were on the new plant table, but as far as I could judge visitors did not crowd round them as I expected they would. They were a typical little lot ranging from the big bright scarlet blooms of Tubergeniana to the much smaller coppery-coloured flowers of a variety of the Greek orphanidea. There were two unnamed species. One was from Turkestan. It was long and pointed in the bud state with the three outer segments of the perianth covered externally—but for a narrow edge of rich yellow—with a pretty shade of red. All the rest of the flower, including the interior of these segments, was of the same rich yellow as the edge. The other unnamed species came from Asia Minor. It, like the orphanidea, was of dull colouring, impossible to describe—dingy green in the centre, then a halo of dingy yellow—then the rest of the petals dingy red mixed with yellow. Smoky might be a better qualifying word than dingy, for the flowers were quite all right, although unassertive. There were some good examples of the deep cream self-coloured Batalini, which Mr. Dykes considers is a colour form of the scarlet Maximowiczi. This species made up the half dozen. In its flowers it very much resembles the low-growing linifolia, although it may be its scarlet is not quite so bright nor its dark base quite so dark. The great difference between the two is in their foliage. Whereas in linifolia it rests on the ground, in Maximowiczii it is upright. There is no use disguising the fact that far the larger number of species tulips require annual lifting and drying off if we wish to keep them going. Left to themselves they soon disappear. The examples in the Hall on May 13th and 14th demonstrated the soundness and efficacy of this treatment, for this is the secret of Mr. Dykes' success. Of all the large red species from mid-Asia, such as Fosteriana, Ingens, Michaeliana, etc., he told me Tubergeniana was the easiest to manage.—JOSEPH JACOB.

PRIMULA WINTERI OUTDOORS IN CO. WICKLOW.

HAVING heard that a gardening friend of mine, Mr. H. de M. Barton of Antrim, had been very successful in growing Primula Winteri, I wrote to him to ask under what

P. WINTERI ON A PERPENDICULAR WALL.

conditions he grew it. I had obtained in exchange two little seedlings from Kew in 1922, which I was very anxious to preserve, as I had previously lost a plant immediately after flowering. Mr. Barton wrote that he grew his plants between stones built perpendicularly, facing north and with a good body of earth behind them to supply the roots with moisture. He added that it seemed to dislike sun and could not stand dryness at the roots. I immediately proceeded to make a rough perpendicular wall of stones, facing north, on the lower part of the rockery here, where it would have a good body of earth behind to keep the roots moist. As an extra precaution against dryness, I arranged a depression above the roots which I could fill with water in case of great dryness. The two little seedlings were duly planted and commenced at once to respond to the new position. One plant grew more vigorously than the other, commenced flowering on January 28th, 1924, had twenty-one flowers open at the same time, and continued to flower till the end of April. All the flowers here were pin-eyed, but Mr. Chittenden kindly sent me on two occasions some thrum-eyed blossoms which enabled me to fertilise with a small camel-hair paint brush. The plants have now set a good deal of seed. We have had here very changeable weather, cold, harsh dry winds, snow, frost, heavy rain and some hail. P. Winteri flowered in spite of all the changes. Twice I saw the flowers and leaves covered with driven snow, but owing to the position it did not remain on long, and at present the plants are looking as healthy as ever. The enclosed photograph was taken by a friend early in April, and though a little late gives a fair idea of the vigour of the plant.

As regards colour it would be interesting to know what Mr. Winter, the finder of it, means by blue. The blue that I have always seen in P. Winteri blossoms was a very beautiful grey-blue, and this blue it has retained here. When fading, the blossoms get at times a slight mauvish tint. It would also be interesting to know whether the soil in its native habitat is calcareous or not, and whether it contains much iron. If collectors would state the character of the soil in the native habitat of plants, especially as regards the presence or absence of lime, it would greatly assist us gardeners and greatly add to our indebtedness to them. Several times when daffodils were drooping from frost P. Winteri was as bright and gay as ever. No weather seemed to affect it.—O'MAHONY, *Co. Wicklow.*

THE CARE OF RHODODENDRONS IN SUMMER.

THE long dry summer of 1921 nearly cleared out all our rhododendrons. A certain amount of benefit was got by saucering the earth round each plant to receive the water. Afterwards a 6in. flower pot was sunk in the earth as close as possible to each root—two to some of the larger ones. This method, by taking all the water 6ins. below the surface, needed less labour and was more effective, as the sun could not evaporate the moisture so easily. The rhododendrons were all watered each day till they had recovered, and about twice a week afterwards, and all were saved. Perhaps some of your other readers would be glad of this suggestion.—R. H. CHAMBERLAIN, *Birmingham.*

THE BRIDGE END GARDEN, SAFFRON WALDEN, AND ITS BOX.

A FEW days ago I was in Saffron Walden and, remembering that a short article had appeared in *Country Life* on the Bridge End garden there, I went to see this strange old example of the Dutch style. The curious scrollwork of the beds round a central fountain had, I think, been trimmed and perhaps replanted by someone who had no idea of making scrolls and curves match, which were evidently intended to be in pairs. They were as intricate as the pattern of a Tudor Knott, about which we have been hearing a good deal lately, but the *smell* of the box in which these scrolls and ornaments were carried out was most offensive. Is there a box which is particularly disagreeable in this respect? If so, I feel sure many of your readers would be glad to have the name of the variety in order to avoid it. The leaves appeared to possess an unpleasant catlike odour. It was not confined to the plants that were in flower; but, possibly, as the leaves grow older the odour disappears, or it may depend on weather conditions. Any information would be gladly welcomed by H. H. W.

A CURIOUS PARASITIC PLANT.

THE accompanying illustration represents a parasitic plant which grows in the sand dunes near the sea at Karachi, India. It has been identified at the Natural History Museum (Botany Section), South Kensington,

A QUAINT PARASITE RESEMBLING A PINEAPPLE.

as Cistanche tubulosa. The tuber resembles a pineapple in colour, size and form, and produces an amber-coloured flower very like a foxglove in size and sometimes scented. The tuber is covered with sand, and from its base comes an aerial root which comes to the surface and runs along the sand for 12ft. or 16ft. and attaches to a shrub with small succulent leaves, on which it feeds. The flowers produce seed-pods containing very fine black seed.—(Mrs.) C. A. CLARKE, *Karachi.*

[There are many interesting parasitic plants, and several have been described in these pages. It would be interesting to know whether this particular plant is edible. —ED.]

THE GARDEN AT BRIDGE END.

CORRESPONDENCE

AN APPRECIATION.

SIR,—I have just read the article on cinerarias by H. W. Canning-Wright in the issue of THE GARDEN for May 17th, and feel I must give some expression of my appreciation. It is a very excellent article indeed, and I am sure all your readers who are interested in these delightful plants will much appreciate the practical hints it offers. My appreciation of THE GARDEN does not stop at this one article, however. I should like to say here how much enjoyment I get out of reading the paper week by week—enjoyment which has been considerably heightened since you remodelled it recently. It deals nowadays with the various phases of horticulture in a way which no other paper has yet attempted successfully, and there seems to be nothing left out of it which the practical gardening man could possibly need. Not only do I find it supplying me with useful information about the culture of all kinds of plants, but as often as not I find myself assimilating from it lots of really interesting and unusual data about their origin and history.—A VERY OLD READER.

GENTIANA VERNA.

SIR,—Had it not been for "Formakin's" interesting note on page 309, I too may have added yet another recipe for the successful cultivation of this gem of our alpine meadows. Now, however, it is laid aside; after all, a recipe is rather tiresome and sometimes quite useless in the hands of the inexperienced. I do not, of course, suggest that all failures are due to inexperience—far from it. No doubt we could all give instances when the discovery of some little detail has at once given us the key which relieves us from further anxiety and at the same time gives us just that confidence so essential in cultivation. Unfortunately, I have never yet seen Gentiana verna growing in the wild, although I am nearer to it than ever before; but for a while longer I must be content with the buttercups and daisies, which are to me just as beautiful, though less important, and supposing I saw an acre I do not think I should want to dig one up, but should be glad to help myself to seed were it seed time; neither would I buy collected stuff, however cheap: rather would I pay treble for a third of the quantity that had been raised from seed and established in pots. These I should plant in full sun at the foot of the rock garden in a good free soil. In the actual planting they would have to go down right up to the neck and be made absolutely firm: this does not mean ramming or trampling, but just what can be done with the hands. Now, I know if these plants are to be as successful as is possible for me to have them I must henceforth keep them down; never must I allow them to get far enough out of the ground to flop about, therefore they must be top-dressed at least twice a year—that is, once after flowering and again in autumn; but with what? Old potting soil, adding a goodly portion of heavy marl that has been dried and broken down, but not quite to powder; if clay is easier to procure, use it in the same way, but in a lesser degree.

Sometimes I consider G. verna to be short-lived, and sometimes the reverse. Probably this is where the difference lies between collected plants and those raised from seed. As regards the bellglass, if I saw one above verna I should feel like smashing it into a thousand fragments, for I believe it hates glass. Quite recently I have planted out from pots 400 odd from a batch raised from seed two years ago. During the whole growing period after germination, which was within six weeks from harvesting the seed, they were never more than a fortnight or so at one time under glass—this at pricking out time and again when first potted up. No doubt my employer, likewise his gardener, hopes to get some pleasure from these plantings, although to a certain extent I have had to adopt the unsuitable pocket method, for where will not their thread-like roots extend unless stopped or turned by some hard substance? For instance, turn a seedling verna out of its pot, and you will find its roots wound round and round its side by the yard.

One other point. Is not "Formakin" rather exacting in asking for a comparison with Anemone angulosa or Adonis vernalis?—J. T. H.

MISTLETOE ON A ROSE TREE.

SIR,—Mistletoe does not grow very frequently on a rose tree (see page 343), so that the record and illustration given are interesting. I have two records of mistletoe, however, on roses. The locality for one of these records was given by Mr. G. W. Stacey as Chorleywood Cedars, who stated that two strong bushes of mistletoe grew on roses there. My record for the other is up in town, and I cannot lay hands on it at present. If roses were larger-growing plants one might expect mistletoe to grow upon them, seeing how many of the same family support the parasite. I have records of it upon apple, crab apple, the two Siberian crabs, the common hawthorn and varieties of it, Cratægus orientalis, C. tanacetifolia, Pyrus Aucuparia, P. Sorbus, P. Aria, cotoneaster, Prunus Cocomilia, plum, pear, medlar and peach. All of the above belong to the rose family.—HORTULANUS.

SIR,—I was much interested in the note from Mr. Meade-King (page 343) on mistletoe growing on a rambler rose in his garden. The rose is certainly an uncommon host for mistletoe, but I have seen it growing on a wild dog rose in the Croft Woods, near West Malvern in Herefordshire. I cannot say if it still exists there, as it is about ten years since I was shown it. Mistletoe grew on a cotoneaster in a garden in Worcester and I knew of at least two instances near Malvern in which the hazel was the host. Does it occur anywhere in England on Scots pine (Pinus sylvestris)? In some of the mountainous regions of south-eastern France it is extremely plentiful on this tree, so that its apparent distaste for it in this country seems remarkable. Possibly the mistletoe on the pine belongs to a biologically distinct race, though in all outward respects it is identical with the familiar parasite of our apple orchards.—N. G. HADDEN, *Somerset*.

ALPINE PLANTS AT MURREN.

SIR,—In regard to the Soldanella alpina so beautifully figured on page 303 and which "R. B. C." suggests (page 344) is more like S. montana as described by Farrer, I fail to see why the plant illustrated does not come under the very variable S. alpina, of which the leaves, moreover, are sometimes as large as in the illustration. But, unfortunately, I have not Farrer's "English Rock Garden" and have little knowledge of S. montana, *Willd.*, except that it is not recorded from Switzerland, but is given in Nyman's "Sylloge Floræ Europæa" as from the Austrian Alps, Lombardy, Transylvania and Basses Pyrénées. Grenier and Godron state that, except for a greater development, the characters are the same as in S. alpina.

In Mr. Wacher's very readable article, "A Plant-hunting Holiday at Mürren," in which appears the illustration of the soldanella, he faithfully extols the beauty and accessibility of the Bernese Oberland, "which is inclined to be avoided by plant-hunters from the fact that it is dubbed a tourist resort to which it is no use going if one wishes to obtain the choicer alpine plants." All who know the Mürren district and its beautiful Blumenthal in June will agree that the ordinary attractive alpine flowers are a glory there, and it is a satisfaction to know they are still plentiful; but the fact remains that there are far more interesting rarities, many worth cultivating, in the Vallais south of the Rhone and in the Italian and Austrian Alps.

Notwithstanding Mr. Wacher's long and entertaining list, he does not mention any rare plants except Veratrum nigrum, Goodyera repens, Lloydia and perhaps Saxifraga cæsia, Androsace helvetica and Cypripedium Calceolus. Veratrum nigrum is only recorded in Switzerland from Monte Generoso and S. Giorgio in Canton Tessin in the south; and, as the big heads near Mürren were only "poking up," it would be very interesting to know if the finder is sure it was not V. album which he saw.

Very probably the "Gagea lutea" on baked ground near the Winteregg cowsheds, "quite recently a swamp," was G. fistulosa Ramond (G. Liotardi, *Schultz*), a most characteristic plant of such ground, whereas G. lutea in Switzerland is a plant of hedgerows, orchards and rich meadows at a lower altitude. Most of us have been deceived by these yellow stars on our first visit to the Alps.

It is extremely satisfactory that Mr. Stewart Wacher has successfully constructed part of his rock garden on the principle observed in nature, after seeing such a wealth of blossom in the swampy Schilt-thal and studying the conditions. There, we are told, the soil is not composed of stone chips with water flowing beneath, but of pure peat overlying rock, with grass roots everywhere to drain the surface, and 1ft. channels (floored with solid rock) cut for drainage of the natural swamp. And so it is in many another Alpine valley.—H. STUART THOMPSON.

SOLDANELLA ALPINA INJURED BY FROST.

SIR,—The case of injury to the above plant by frost, mentioned by "R. B. C." on page 344, reminds me of some of my experiences. I had a small bush of Salix Myrsinites established in the garden for some years. In this country the species ascends to an altitude of 2,700ft., and could be classed as one of the lower alpines. It came into leaf at different times in the garden, according as the late winter was mild or cold. One year it came into leaf rather early, and a late frost blackened and killed every leaf. The bush put out some leaves afterwards, but never fully recovered and soon died. A bush of the cultivated Japanese Salix gracilistyla came into full leaf in the garden one spring, but a late frost killed it. My conception of the occurrence was that the plant would have been safe if merely in flower, but that the leaves expanded in the lowland garden before the weather was safe for them, and that they had no natural covering, such as snow. It is true that many alpine flowers come into bloom as the snow melts and when the weather is mild, but I have seen them completely covered with snow within half an hour. In favourable weather alpine plants in gardens grow quickly, but the new growth of some of them is very tender.—J. F.

NARCISSUS FORTUNE.

SIR,—I have just been reading in your issue of May 17th, the Rev. Joseph Jacob's notes on flowers at Birmingham. and I should like to say that I feel rather to blame for his somewhat disparaging remarks about this wonderful daffodil. The flowers he saw at Birmingham of this variety were some that I showed, and they were really quite out of condition; in fact, almost dead. Mr. Chapman said to me at the show that I ought not to have put them up, and I now realise that he was quite right, as they have given an unfair impression of the variety. Fortune is a first early variety, and this was an extraordinarily late season, and although I realised when cutting the flowers a day or two before the show that they were even then much past their best, I thought I should never again have a chance of showing it at Birmingham, and so put them up. Mr. Jacob, of course, could only judge from what he saw, but if he had realised that besides having travelled a long journey the flowers he was looking at had been more than three weeks in bloom, and if he could have seen the clear and intense brilliance of their perfectly formed deep lemon gold perianths, and the astonishing splendour of their great glowing deep flame orange-red crowns in my garden on April 1st, when nothing else was out except Golden Spur in the grass, I feel quite sure that he would have formed a very different opinion.—GUY L. WILSON, *Co. Antrim.*

THE USE OF GARDEN LABELS FOR ALPINES.

SIR,—There is no doubt that the Rev. Edward S. Lyttel (page 345) is an enthusiastic cultivator of alpines and loves them or he would not take so much trouble about the naming of the varieties, etc. But the reverend gentleman denies titles to others that he would claim for himself, personally. His second venture in the field of criticism does, however, show up more clearly the helpful hints contained in Mr. Gerald Hillier's original article (page 211) on the labelling of alpine plants.—G. G.

AMERICAN NOTES.

SIR,—In THE GARDEN, January 19, page 32, "W. I." dealt with various thalictrums, including the beautiful T. dipterocarpum. It might be of interest to know that this species is perfectly hardy in northern New Jersey, where the temperature has touched zero on several occasions since I planted it, three years ago. I have it planted on a north border on medium loam, and give it no protection beyond what other perennials receive, that is, a few old pea boughs and a little litter. It grows at least 7ft. and flowers beautifully. The last two seasons I have saved from half a dozen plants quantities of seed; last year I had several hundred young plants which, as I had no use for them, I gave to a nurseryman friend. The seeds were sown in the open in May, 1922, and made quite strong crowns by the autumn. My experience with the plant in Kent led me to expect dying out, but it would seem that T. dipterocarpum is absolutely hardy. I might add that various other things I expected would prove "miffy," including border and perpetual carnations, are quite equal to withstanding zero weather if given a little protective litter to break the bleak winds and warm sunshine that come along in March. While everything is buried in snow or ice all is well, but when this melts the dangerous time begins. Pansies and primroses laugh at the cold providing they have a little straw or litter shaken over them to prevent alternate thawing and freezing. I had quantities of pansies, violas, etc., under rough frames made of Cel-O-Glass, a material that is practically the same as Spondite—collodion-coated mosquito netting. This material without any other protection is keeping pansies and other plants in great health. Even snapdragon cuttings and sweet peas came through, although during this winter we had no protective snows as we did last year.

Reverting to thalictrums again, a firm over here is offering T. Fendleri, which I have never seen offered before and with which I am not acquainted. It is a native of the Western and Southern States, and apparently is not generally known, due probably to the fact that it is a dicœcious species and therefore shy at seeding. The concern offering it has apparently worked up its stock by division, as the plants are said to be males. That it is not common is evident from the fact that 5 dols. is asked for a plant. Bailey's Cyclopedia quotes T. Fendleri as being a strong grower with yellow and violet flowers, the foliage being somewhat akin to that of an aquilegia. A friend tells me it is not so fine as T. dipterocarpum, which, by the way, is very scarce this season.

Touching upon the question of blue hydrangeas, you may not be aware that the New Jersey Experiment Station has conclusively proved that acidity of the soil is responsible for the blueness. Experiments are not completed, but I have seen enough to convince me that the explanation is correct. Naturally acid soil or soil artificially made acid not only induces blueness, but by controlling the degree of acidity the flowers can be made to vary through all shades of rosy mauve, pastel shades to sky blue. Purely alkaline soils ensure pink shades. The deep-coloured varieties like Trophee yield a wide range of tints when treated with acids. A certain amount of details have already been published, but after this year's tests a complete bulletin will, I believe, be published by the Experiment Station.

Regarding Lonicera nitida, a few firms here have listed it for a number of years, but it is not widely known, and it is said not to be hardy in the north-eastern section. In the north-west it does well, and in California, around Los Angeles, it makes such rampant growth that some nurserymen have discarded it. No one, however, has suggested it as a hedge plant. I am giving it a test this season and do not anticipate much trouble, as my two 6ft. Pyracantha Lelandi planted a year ago suffered no serious injury. My only loss apparently is one new delphinium raised by a north-western enthusiast.

The little cornuta hybrid viola which I have named Jersey Gem has survived both in the open and in the frames. It began flowering nearly two weeks ahead of Geo. Mennig, which is a weedy thing compared with it. Jersey is a brighter blue than Papilio or Lord Nelson. The latter is a fine plant, but is too dark and too near a bedding viola to be a cornuta. Jersey Gem has petals slightly fluted. It is distinct from any cornuta form I have seen, and many florists see in it a substitute for Princess violets when the latter are past. Anyway, it will have a good testing this season, for after growing it three years I propagated several thousands last autumn, while a well known nurseryman catalogued it even to the extent of having a colour plate.

As you know, we cannot import plants these days, therefore to appease my appetite for violas I keep raising batches of seedlings. From Dobbies' seed I have secured several fairly good bedders, and one that is equal, I think, to Lady Knox, but I still await one like Moseley Perfection and W. H. Woodgate. Jersey Gem, by the way, came out of seed sent me by Mr. J. M. Bridgeford of Messrs. Watkins and Simpson. I am not sure as yet, but I suspect it is the plant they lost several years ago. Being something of a "crank" on violas, I am trying to raise V. bosniaca. V. Munbyana I am flowering shortly for the first time. It makes such enormous roots that I think it will be useful for this climate. I am also just about to flower Viola cucullata, a most pleasant thing. The plants I got from Virginia last season were full of seed and the seedlings are coming up in thousands.

Primroses are a great success this season, really for the first time, as last year I took the litter off too soon and the March winds ruined them. In the Munstead strain I have some practically pure vulgaris. I have also the blues, and quite good at that. In the frame I have seedlings of several of the hybrids and species of primulas, including japonica and rosea. The seed laid dormant nearly two years, but it is germinating, so I have hopes. Beesiana I expect to flower this season, as a friend sent me some plants last autumn.—T. A. W., *New Jersey.*

SOUTHAMPTON ROYAL HORTICULTURAL SOCIETY'S SHOW

THE Council of the above Society has every reason to congratulate itself on the high standard and excellence of its first spring show, which was held in the Pier Pavillion on May 13th and 14th. It is also to be hoped that it proved a success financially.

Judging by the many magnificent groups of rhododendrons and other flowering trees and shrubs, one could almost imagine themselves viewing a Truro or Falmouth exhibition. With the ever-increasing interest in hardy trees and shrubs, and the introduction of so many of these good plants from China, which can be as successfully cultivated in the many beautiful gardens in the South of England in the open air, just as well as in the gardens of the West, it is to be hoped that the interest and enthusiasm at this first attempt will in no wise be allowed to flag, but that another year competitive classes will be introduced, and sufficient interest taken, encouraged by this first attempt of a spring show in the South of England to make it a rival show to that of Truro and Falmouth in the West.

It was unfortunate that the date of this exhibition clashed with one of the fortnightly meetings of the Royal Horticultural Society at Vincent Square, otherwise the trade exhibits might have been more numerous. Rhododendrons and other flowering trees and shrubs were a feature of this exhibition. From the garden of the President, the Right Hon. Lord Swaythling, Townhill Park, Bitterne, Southampton (gardener Mr. F. Rose), came a beautiful exhibit, which comprised Rhododendrons Loder's White, Dr. Stocker, campylocarpum, campanulatum, Princess of Wales, Davidii, Standishii, and many seedlings and hybrids, backed with vases of berberis in variety, flowering cherries and brooms. This attracted much attention. (Large gold medal.)

Messrs. R. Gill and Son, Falmouth, had a very extensive exhibit of rhododendrons and other flowering shrubs, herbaceous plants, tulips and anemones, very fine vases of Rhododendrons Nuttallii, Edgworthii, Aucklandii, Ernest Gill, Falconeri, and some fine unnamed seedlings, together with Embothrium coccineum, Crinodendron Hookeri, a fine basket of the New Zealand forget-me-not, Myosotidium nobile, masses of Darwin and May-flowering tulips, and a grand lot of anemones of their well known poppy strain. (Large gold medal).

Digitized by Google

Mr. W. J. Whitaker, Pylewell Park, Lymington (gardener Mr. W. F. Hamilton), had a very attractive group of flowering shrubs, schizanthuses and new seedling carnations. (Small gold medal.)

Messrs. Barr and Sons' contribution was a magnificent display of May-flowering and other tulips—over one hundred well filled vases in many varieties. (Large gold medal.)

Mr. T. H. Lowinsky, Tittenhurst, exhibited sixty trusses of his wonderful hybrid rhododendrons in many shades of beautiful colours, some trusses of R. Wightii and a plant of the rare R. Griersoniana in flower. This exhibit was much admired. (Large gold medal.)

Mr. Elisha Hicks staged a very fine exhibit of well grown roses, some of the outstanding varieties were Mme. Butterfly, America, Mrs. H. Wumett, Mrs. F. Hobbs, Clovelly, etc. (Large gold medal.)

From Mr. Lionel de Rothschild's garden at Exbury, was exhibited a magnificent lot of rhododendrons and other flowering shrubs, cherries, brooms, heathers and Illicium religiosum. (Large gold medal.)

Messrs. Hillier contributed a large group of flowering trees and shrubs, pyrus and cerasus in variety, and Fremontia californica; the group was furnished round the outside with baskets of alpines and herbaceous plants. (Large gold medal.)

Mr. E. M. Burnett, had a small group of cut flowering shrubs, rhododendrons, camellias, ericas and Daphne neapolitanum. (Silver medal.)

Messrs. Ladhams constructed some rockwork on either side of the entrance hall, which was well furnished with many choice shrubs and herbaceous plants and alpines, a very pleasing exhibit. (Large gold medal.)

A very large group of shrubs, herbaceous plants and alpines was staged by Mr. G. Reuthe; rhododendron hybrids and species were extremely good, a very meritorious exhibit. (Large gold medal.)

Messrs. Rogers occupied the whole of a small room adjoining the hall and displayed a very fine collection of choice alpines on rockwork, backed with fine rhododendrons, Japanese maples and other shrubs. (Large gold medal.)

Messrs. C. Smith and Son sent over from Guernsey a choice collection of cut flowering shrubs, rhododendrons species and hybrids, some choice camellias, magnolias, brooms and acacias. (Small gold medal.)

Messrs. Toogood and Sons staged a large group of May-flowering and other tulips, carpeted with forget-me-nots. (Small gold medal.)

Mr. C. Englemann staged a very choice group of carnations, which was greatly admired. (Small gold medal.)

Mr. G. H. Dalrymple occupied a large piece of staging with a very fine collection of well grown and well flowered Primula pulverlenta pink seedlings. (Small gold medal.)

Messrs. Blackmore and Langdon contributed some of their fine delphiniums, double begonias and some good baskets of polyanthuses and pansies. (Silver-gilt medal.)

Some good hydrangeas, crotons, Acalypha hispida, heliotropes, ferns and palms, together with some vases of tulips, were exhibited by Mr. E. Wills, Southampton. (Silver-gilt medal.)

Mr. B. Blampied of Guernsey staged a fine lot of May-flowering tulips and Spanish irises. (Silver-gilt medal.)

Mr. F. Longster, Southampton, constructed a large piece of rockwork, which was well planted with acers, dwarf phloxes, anemones and primulas. (Silver-gilt medal.)

Mr. E. J. Wiltshire, Netley, staged carnations, polyanthuses and auriculas. (Silver-gilt medal.)

Miss Rayner had a small collection of alpines. (Silver medal.)

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Darwin Tulips (C.).—If the buds from the small bulbs are removed, the bulbs should certainly be a better size for next year. If it is desired to sort the tulips into varieties or to make sure that there are no "rogues" among the different clumps, our correspondent must allow the flowers to develop and break them off as soon as it is decided that they are the same or different. The breaking off of flowers of tulips before they have had time to develop fully saves nourishment for the bulb because the ovary tends to grow while the flower is on the stem and the growth of the ovary monopolises the nourishment which would otherwise go to the formation of the bulb for next year.

TREES AND SHRUBS.

Cuttings of Box Edgings (E. B. N.).—Insert cuttings made of the young growths from August to October under cloches or in a handlight under a shelter of a west or north-west wall. A more frequent method of increase is to layer the old or leggy plants.

Wistaria Not Flowering (D. A.).—The wistaria is not a very suitable plant for culture in a cool greenhouse. Being a hardy climber the heat of a greenhouse encourages very vigorous growth and apparently no pruning has been done. The usual method is to cover the allotted space with main rods or branches and then keep all side growths pruned or stopped to three or four eyes to form flower buds. Wistarias are frequently grown in large pots or tubs for the decoration of large greenhouses and conservatories in early spring. The plants are moved inside a few weeks before flowering. When the blooms fall the plants are stood outside where the conditions are much more suitable for the growth of flowering wood.

THE FRUIT GARDEN.

Pear Doyenne d'Eté (Felsted).—There is only one point against this variety as a fruit; it does not keep long when in a fit condition to eat. Furthermore, the trees should be double-grafted. The fruits are small and borne on compact-growing trees, and are considered the best of the very early sorts. The other variety referred to (Laxton's Superb), is also a good one and keeps a little longer. Its parents are both first-class, the flavour is good, the fruits are handsome, they fill a gap between Doyenne d'Eté and Williams' Bon Chrétien and should be in all collections.

FRUITS UNDER GLASS.

Pruning and Stopping Vines ("Torquay").—As the vines have not been pruned in the usual way, it will not be safe to prune them now, as they would bleed freely and become weakened. The current year's shoots should be rubbed off, leaving only one at the base of each of last year's branches. Where such basal shoots are bearing bunches they should, in turn, be stopped at two or three joints beyond the point where the bunch is growing. All small shoots growing again on the denuded stem should be rubbed off when only 1in. long or so. After midsummer it will be quite safe to cut out all the denuded stems back to the one shoot retained of the current year's growth.

MISCELLANEOUS.

Making Use of an Old Well (J. W. M.).—The filling up of the disused well will not cause the water in it to rise 8ft., or so, to the surface. The 2ft. level of the water in the well is its normal level, and it will rise a little or sink according to weather conditions. In any case it is not likely to give trouble near the surface. Cementing would be necessary to retain 2ft. or 3ft. of water near the surface for the purpose of growing lilies; the rim at the top being constructed of stone. For a moraine, or bog plants, possibly puddled clay would answer well enough if the right material is used for the moraine plants.

Slug-Infested Soil (E. L. G.).—Unless slugs are placed in dry, unslaked lime or salt and retained there they will not be killed by applications of these ingredients. They slough themselves free of any dusted applications. The only way to deal with the pests now is to kill them around lettuce and similar plants and about three times a week scatter soot round each specimen. Gas lime would destroy many in the autumn where the soil can be left uncropped for two months afterwards. Digging deeply, so allowing frosts freely to enter the soil will hinder the breeding of slugs considerably and give seedlings a better chance to escape them in spring.

Insects for Identification (H. S., E Yorks.).—The creatures in the soil are white worms (Enchytracus sp.). They are apt to damage roots when the amount of organic matter in the soil is low, otherwise they feed on decaying vegetable matter. Heating the soil is the best way of killing them. Our correspondent might try watering the soil with water at 110° Fahr., not higher. This will not damage the plants.

Salt for Examination (W. R., Herts.).—The sample sent appears to be impure salt, which may be used for any purpose to which agricultural salt is put. It may also be used on gravel walks for weed killing.

How to Combat Slugs (G. W.).—The most satisfactory way of dealing with slugs is to trap them with such a trap as the V.T.H. slug trap. Another good way is to go out after dusk armed with a pair of scissors and a bright lamp and cut in half all that are seen. Hollowed out skins of oranges are good traps, so are cabbage or lettuce leaves laid on the ground, and hollowed out pieces of potato or carrot.

The Use of Sulphate of Ammonia (H. G.).—This chemical fertiliser is valuable applied to all garden crops, especially vegetables. Neutral sulphate of ammonia is a dry, crystalline chemical fertiliser and supplies a very large percentage of nitrogen. It should always be stored in a dry place. Applied in a dry state half an ounce per square yard will be a right quantity to use; in a liquid form, half an ounce dissolved in one gallon of water. As a surface dressing in a dry state apply 1 oz. per 4yds. run of row of plants and lightly hoe it into the soil. For established fruit trees, 3 oz. per tree. For pot plants 1 oz. dissolved in 2 gallons of water. Applied in a dry state, a small teaspoonful to a 10in. pot.

Peculiarities of the Arum (T. H.).—It is by no means an infrequent occurrence to find that the leaf below the spathe of an arum takes on similar coloration, and this is the case in the specimen sent. Why it should do so is a puzzle, but scarcely more of a puzzle than that the leaf which encloses the spike of flowers in the arum should be differently coloured from the rest of the leaves of the plant, or that the petals should be brightly coloured while the foliage of the plant is green.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Salads will require careful attention during the summer months, especially if we experience a hot dry spell of weather. Seed of mustard, cress and radishes should be sown weekly, choosing if possible a partly shaded border where plenty of moisture can be afforded to encourage a quick and free growth. Lettuce seed should be sown every fortnight on good ground, as the plants soon become useless if the soil is poor and dry.

Seakale.—The "thongs" that were planted a few weeks ago are now sufficiently advanced to enable the necessary disbudding to be done. The strongest shoot should be chosen, and the remainder rubbed off. A dusting of soot between the rows will be beneficial, and a few weeks hence a sprinkling of agricultural salt may be applied.

Thinning Crops.—This operation is most important, and all crops ought to be thinned directly they are large enough to handle. Many crops are partially ruined by overcrowding, while the quality is always inferior. Among those that will need attention are parsnips, onions, beet, carrots, turnips and spinach. The latter rarely gives satisfaction in the kitchen unless it is well grown. Frequent sowings of spinach are necessary to keep up a supply, and if not already done the New Zealand variety should be sown. This will produce a useful crop when others fail through dry hot weather.

Cauliflowers.—If the weather proves dry, the plants put out a few weeks ago will need water, and liquid manure may also be given. As plants become large enough they should be planted out.

THE HARDY FRUIT GARDEN.

Newly Planted Trees.—At this season we occasionally get a dry spell of weather, and then newly planted fruit trees will require water, expecially those at the base of walls. A mulch of short manure will help to conserve moisture in the soil and thereby reduce the labour of watering. Mulching is strongly advised for fruit trees growing in a shallow, hot soil.

THE FLOWER GARDEN.

Seed Sowing.—Now that the frames are empty, a start may be made with sowing seeds of most perennials and many alpine plants. Provide the pans or pots with ample drainage, and the compost should consist of fibrous loam 3 parts and leaf-mould 1 part, to which add a liberal sprinkling of sharp sand. Cover the seeds with finely sifted soil; but, before sowing, the pans should be well soaked with water. Keep the pans shaded, and afford water carefully so as not to disturb the seeds. When the seedlings are large enough, prick them off in boxes or in prepared nursery beds in the open.

Flowering Shrubs.—When these have passed the flowering stage, any necessary pruning should be carried out. Some of the growths will need thinning and cutting back to prevent overcrowding, and to produce well balanced specimens. Lilacs are improved by cutting out a lot of the old wood, and thus allowing space for the young shoots to develop. Many plants of a semi-climbing nature planted at the base of walls may also be dealt with, at the same time tying in growths needed for extension and filling vacant spaces.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Celery.—Plants in boxes and frames should not be allowed to suffer through not having sufficient space or root room, therefore they should be set out in the trenches at the first opportunity. It is wise to examine the plants and make certain that they are sufficiently moist at the roots before lifting. The plants should be raised from the soil in such a way that each one will have a good ball of earth, then planted with a trowel, 9ins. apart each way in the trenches. For a week or two an occasional watering should be given the plants in the late afternoons or evenings.

Hoeing.—The hoe should be kept constantly in use, not only to keep down weeds but also to stir the surface soil, among the growing crops. By frequent hoeings a fine tilth is created on the surface soil; this acts as a kind of screen and prevents in dry weather undue evaporation, thus conserving the moisture in the soil. Weeding, too, among the various young crops will require to be done by nimble fingers.

Potatoes.—In gardens where the potato haulms are sufficiently grown, the soil should be drawn up on either side of the rows. Some knowledge is even necessary to do this work properly. The soil on top of each row after earthing up is done should be left in a concave or grooved formation, so that the potato roots near the surface will obtain moisture when rain falls.

Vegetable Marrows.—Frames which have been cleared of bedding plants may be prepared by having small pits taken out in the centre of each, and about a barrowload of well decayed farmyard manure placed therein, over the manure spread sufficient good loamy soil to form little mounds, and then make firm. Plant the marrows or cucumbers on the mounds. The frame lights should be kept closed except when the sun is shining on them, and the plants and sides of the frames should be frequently sprayed to create a genial growing atmosphere. This practice should be continued until the plants are well grown.

THE FLOWER GARDEN.

Gypsophila elegans.—Where beds of young pinks are rather thin, and a good deal of black earth showing, one may with advantage scatter thereon the seeds of Gypsophila elegans. After sowing, cover the seeds with a little fine soil. This hardy annual will not only fill up the spaces, but it will expand its finely branched stems and dainty flowers when the pinks are out of bloom.

Narcissus Poeticus plenus.—Those who wish to have narcissi flowers in June should grow the double white or as it is sometimes called, the gardenia-flowered narcissus. They look very effective when grown and associated with variegated grass and catmint. Unfortunately, it has a nasty habit of producing flower buds which never open. I have counted as many as twenty-four flower buds on a clump of plants and only four blooms opened. Overdryness at the roots may possibly cause such bud blindness.

Sweet Peas.—It will be necessary now to have the large poles erected by the sweet pea plants, so that the trainers or wire netting, whichever is to be used, may be fixed thereto, and thus give the plants their needed supports.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.)
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Chrysanthemums.—If not already done, soil should be prepared for the transference of chrysanthemums into their flowering pots. It is an advantage if the soil is prepared at least a week before it is required, and it should also be turned over once or twice during that time. A good medium loam is best for the purpose; and whether any or a little leaf-soil is added depends on the character of the soil. A heavy loam will benefit by the addition of some leaf-soil, or some old mushroom-bed manure may be used instead. A 6in. or 7in. potful of fine bone-meal should be added to every bushel of soil, with enough coarse sand or other gritty material—according to the character of the loam—to keep the whole open and porous. A dusting of lime should also be added, as potting soils are usually cut from old pasture land that has too often been neglected as regards liming. The required number of pots should be washed and crocked in readiness; the size will depend on the size of the plant it is desired to produce. If single-stem plants are grown for the production of large blooms, pots 8ins. in size should be large enough for ordinary purposes. Large blooms are not so generally in favour, but although some people do not care for them, they are valuable for the decoration of large rooms, where the smaller decorative varieties would be somewhat lost. Coming to the decorative section and singles, they may be grown singly in 9in. pots, or two in a 10in. pot. If larger specimens are required, three plants should be placed in a 12in. pot. The plants should be potted firmly, and are best stood close together at the bottom of a wall. Here they may remain for several weeks, until they get well away at the root. Standing close together, a moister atmosphere is maintained than if they were stood out at once in their summer quarters. Water should be carefully afforded at the roots until they get a hold of the new soil. Plants in 6in. or 7in. pots for the stages should also be potted up, taking care to use the varieties that are best suited for this purpose. They should be kept well pinched to keep them dwarf and bushy.

South African Bulbs, such as nerines, freesias and lachenalias, as they ripen off and their foliage dies down should be stood together in cold frames where the lights can be kept over them during the summer. Nerine Bowdeni is more or less evergreen and should never be dried off completely as in the case of the other species and varieties.

Daturas are very useful and handsome when planted out in a large conservatory. Excellent specimens, however, can be grown in large pots or tubs. These plants are best grown as standards some 5ft. or 6ft. high, as their drooping, trumpet-shaped flowers are displayed to best advantage. They are readily propagated at this time by means of the smaller side shoots, which root readily in a close case with slight bottom heat. They grow quickly and soon make useful plants.

J. COUTTS.
Royal Botanic Gardens, Kew.

OBITUARY

E. A. MERRYWEATHER.

IT is with deep regret that we learn as we go to press of the death of Mr. E. A. Merryweather, of the well known firm of Messrs. Merryweather and Sons of Southwell. Mr. Merryweather had a very long and painful illness.

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No 2742 Saturday, June 7th, 1924 Price THREEPENCE

The Kelway Colour Border

is planned for continuity of bloom as well as colour effect. Your garden is of enduring beauty from early Spring to late Autumn, and so continues for several years, as a result of the minimum of cultivation, expense and attention.

These Colour Borders have evolved from many years of experience, and clients get the advantage of securing, amongst other subjects, the world-renowned Kelway Specialties in Hardy Plants.

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

We are only too pleased to advise.

WRITE NOW to the inventors of Colour Borders:

GOOD COOKING

AS a palliative after the excitements and wonders of Chelsea, we are beginning in this issue a section devoted to the cooking of vegetables and fruits. In this country we are supposed to grow both vegetables and small fruits equal to, if not better than, any other country on the globe, and yet our use of vegetables is deplorable. In little restaurants in the country on the Continent you can always be certain of having a good egg dish and the vegetables well cooked. What more can even the greatest of epicures want than a perfect omelette, a dish of peas cooked to perfection, a salad and some cheese, and some ripe pears and coffee to end up with? It is a meal fit for the gods, and yet it is almost unknown in this country.

As a nation we are deplorable in our lighter cooking. Roast beef and kippers we can deal with better than anybody else, but who wants to keep their entire body and soul together by eating roast beef and kippers? There are such things as salads and vegetables which are not boiled in gallons of water and thrown in a dish to be served with the meat. There are such things as vegetable dishes served alone and served with due pomp and ceremony—and yet they are seldom given in the British Isles.

I happen to be fond of good cooking, and even have made a hobby of the preparation of good food, so I feel that I am upon firm ground, which is just as well, as discussions upon cooking are just as fast and furious as those on such subjects as rare alpines or the best rhododendrons. Apart from everything else, we have to eat to live, and we might as well eat palatable and good tasting food as not. This is not greed, only sound common-sense. Almost every doctor will tell you that food you enjoy is food easily digested, whether it be pigs' feet, porridge, or *pâté de foie gras.* Readers may rest assured that I am catholic in my tastes. I like every vegetable with the one exception, a parsnip, and to that I have a violent and perhaps unreasonable objection. Mention of parsnips may be few and far between in the pages of this paper, for the very thought of them gives me a sinking feeling, but for every other vegetable and fruit, whether grown above or below ground, I have a distinct partiality, and for them my digestion functions properly.

I should like, at this point, to mention one fact, and that is that cheese should be used with moderation and caution in the cooking of vegetables. Few English cooks know how to use cheese in cooking in the proper proportions, and that dish which is labelled something "au gratin" is usually a waste of good cheese and of good vegetables. Cheese is noticeable for its strong taste and vegetables for a delicate flavour which lingers pleasantly on the palate. The flavour of cheese kills all good vegetables. One vegetable has a bad name in this country owing to ill usage, and that is garlic. Nothing is pleasanter than a faint trace in salads, and yet few know how to use it properly. It is quite sufficient to rub the inside of a dish once around, but two turns might ruin what might be a perfect salad. Garlic will make or mar a dish and should be used with respect and discretion. An article will be given later on the use and misuse of garlic.

The first recipes deal with vegetable soups and are followed by—but why should we give away our secrets? The material for this and the following articles is supplied by M. Elles of the Maison Basque in Dover Street and by his chef. This is a restaurant that specialises in good French cooking, and so our readers may rest assured that all dishes mentioned in these articles are not only excellent to taste, but are also nutritious.

But this talk of food whets my appetite, and I am away to my dinner. We only ask that if any reader has a particularly fine vegetable or fruit dish on his menu, he—or she—should be willing to share it with other enthusiasts and should write to us, giving full particulars, so that we may broadcast it in our columns. We also have ways and means of testing dishes, jams, pickles and so on, and shall be delighted to give advice upon this most important subject. E. H. M. C.

We should like again to remind our readers that the Mrs. Edward Harding Peony Cup is offered for award at the next show of the Royal Horticultural Society, to be held at Vincent Square on June 11th. This is awarded for the best exhibit by an amateur of three flowers each of six varieties of peony. It is hoped that many amateurs will send in exhibits and so help to popularise this fine plant.

SOME LILIES IN THE JUNE BORDER

THE BEAUTY OF LILIES AS BORDER PLANTS HAS ALWAYS BEEN RECOGNISED, BUT THEY ARE, PERHAPS, A LITTLE NEGLECTED IN OUR GARDENS. THIS ARTICLE BRINGS TO YOUR NOTICE SOME OF THE MORE POPULAR VARIETIES.

JUNE is a month of many competitive flowers, when Nature—in prodigal mood—showers her treasures into the arms of the gardener. Yet, in the midst of it all, one flower—the lily—continues to rise resplendent, triumphant, all-conquering over all. She is a conservative flower that does not spend all her varieties at once; others, no whit less beautiful, none the less fragrant, are in reserve—right up to the September days when LL. auratum and speciosum will signal the termination of a long pageant of glory. But to-day she is generous enough and the garden is aglow with many a brilliant hue, the air is heavy with a powerful fragrance, the lover of beauty and form is filled with delight at the profusion with which he is surrounded.

Looking backward to the cool, moist days of October, with the dying leaves swirling round us in a continuous shower, it does not seem long since we committed those bulbs to the earth in hope. To-day, even though we knew to a large measure what to expect, it is far more difficult to realise that so rich a feast of wonder lay dormant within those fleshy bulbs. A miracle seems to have happened—yet it is a miracle that will happen again, for anyone who may wish it repeated. Let us cast aside all thought of the cultural aspect of the matter and merely enjoy the present and the flowers that be or soon are to be, for budhood is in many varieties but little less attractive than actual flowering.

Here in partial shade we discover a good example of this budhood, for those are Lilium Coridion, the flowers of which will not expand until the last days of the month. When they do open they will become flowers of a rich clear yellow. It has suffered from a reputation of being difficult to grow. However, it is not difficult when planted in loamy soil to which some peat and sand have been added, combined with regular moisture and partial shade. As we turn from contemplation of this choice little plant we are left in no uncertainty as to whether L. croceum, the cottager's orange lily, is in flower. Through the trees comes a glint of fiery gold that could only be produced by that common old garden favourite. No need to worry over proper soil for this. Give it sunshine and an open position away from trees, but where the base of the stem is buried among other plants, and it will annually increase in numbers, rising upwards to a height of 5ft. to 7ft., with a large number of fiery orange flowers on every stem. How the children love to be lifted up to smell and to bury their noses amid the dangling stamens, withdrawing with shrieks of laughter at the fact that their faces are stained with the golden dust.

A FINE JUNE BORDER LILY, L. DAURICUM.

The Dahurian lily, L. dauricum, has an interesting story, and those who take a definite stand as to whether varieties should be ranged under dauricum, umbellatum, Thunbergianum or elegans must be prepared for either contradiction or agreement. Originally the lily came to us from Siberia and was named dauricum by one and spectabile by another, so that its very advent was marked by dissension. Then the growers took a hand and raised improved forms, which they named umbellatum. To-day we stand the possessors of a heritage which lights the June border with a splendid array of vivid colour that, good as it is *en masse*, is worthy of still closer scrutiny. Here is dauricum Prince of Orange, the earliest to flower, 1ft. high, with showy apricot flowers spotted with black. Here, rising to 15ins., is elegans Orange Queen, a clear bright orange plentifully dotted with small black spots. There, still taller and reaching 1½ft., elegans sanguineum in deep red.

Umbellatum varieties are such strong growers that we have placed them in the shrubbery to display their glorious colour against a dense background of deep green glossy leaves, and they thoroughly appreciate the cool shade at their roots, provided these are not too dry and the heads can rise clear into the strongest sunshine. Our choice has fallen upon Diadem—one of the very best of all—in bright crimson, each petal having a central yellow streak. Grandiflorum, in light orange red; erectum, red flushed with orange; and Sappho, light orange tipped with red. These are all of the grow-themselves order, and one cannot claim any special credit for their fine condition; but they do look well.

Back again to the border, however, and right down to the sunniest end where, with a full south aspect and a kindly brick wall at the back, we have ventured three bulbs of L. longiflorum. Even if their coming be delayed to July, however, it is worth growing them. The lower leaves are slightly touched by late spring frosts, but the giant white buds are in condition and, whether it be June or July, those elegant fragrant white flowers will expand into magnificent trumpets of spotless purity. The reward is worth the risk, and if—another time—failure comes, well, we shall probably try again.

Here is Lilium monadelphum, according to Kew, though in many gardens there is confusion and the name colchicum and Szovitzianum are both in use. The type is rich yellow and more or less copiously spotted,

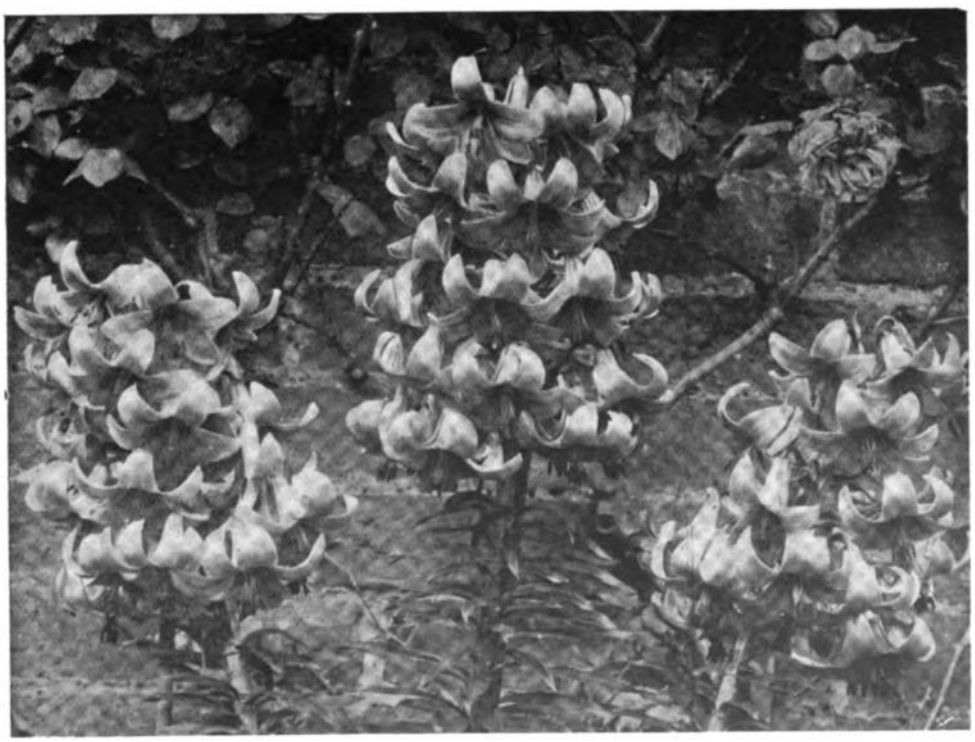
Digitized by Google

while the stamens are joined at the base. In Szovitzianum the flowers are larger, paler in colour, with bright red anthers and the segments less recurved. The latter at its best is a glorious plant, and where it takes kindly to a position increases its bulbs freely. Pyramidal clusters containing as many as thirty flowers are sometimes produced when the bulbs are well established. The clump we are examining has been planted five years, which accounts for the large number of blooms. The first spring after planting I always fear that something has gone wrong, for the plant appears just to stand still and makes no progress whatever; but time will prove this false and the second year will give you bloom, and then there are the succeeding years, too, rich in compensation for one year's wait.

Very beautiful, very easy and very early are fair descriptions of the Yellow Turk's Cap, L. pyrenaicum. The leafy stem alone is full of beauty, and then there is the crown of pendent flowers, in yellow shaded with green, dotted by black and illuminated by a touch of brilliant scarlet on the anthers. This, standing at a height of 3ft. in a close tuft, forms an outstanding feature of chaste and delicate beauty of which one never wearies. L. rubellum is another of our experiments, for truth compels the confession that it is not reliably hardy, especially as it blooms so early, for—in a forward season—one may see the flowers fully expanded in May. Success is only achieved by surrounding the bulbs with rubble and stones so that they never come into contact with the soil, otherwise they disappear by rotting during the winter. A partly shaded spot with a good body of leaf-mould and loam round the rubble will do the rest, and your reward will be deep rose flowers of exquisite beauty. There may be a surprise in store here, for it is not uncommon for the first flowers to come nearly white, the rose colour only developing in later years when the bulbs have become established.

Brilliant colour—glossy scarlet—a slender graceful habit and easy of culture in most soils, these are the amiable characteristics of L. tenuifolium, a charming little lily, 1½ft. tall, of the Turk's Cap order. If you want to be especially kind to it, here is its chief requirement: it loves a little bit of peat added to the natural soil, and the welcome shade of a companion plant that shelters the lower third of the stem will be appreciated.

LILIUM CANDIDUM, THE MADONNA LILY.



THE FIRM RICH YELLOW HEADS OF LILIUM MONADELPHUM.

Finally, and with a query mark against it as to whether it will be late June or early July in its flowering, we do admit pride in our noble clumps of that old-fashioned glory of the cottager's garden, the Madonna lily, L. candidum. There are two secrets behind those splendid examples, one at planting time, the other merely a question of leaving alone. When we procured our bulbs, we put them into a bag filled with powdered sulphur and shook all up together and then planted them thickly covered with the yellow dust. No gardener but Nature has handled them. A spadeful or two of manure, very old and so rotten that it was quite black, has been carefully spread over the bulbs in late July, and to-day you see the result. Stems towering upwards 4ft. to 5ft. high, thickly furnished with fifteen or more giant buds crowning the apex of every stem, of which there are more than twice as many as when the original planting was done. H. W. CANNING-WRIGHT.

VEGETABLE SOUPS

THERE are two vegetable soups in which we, as a nation, excel; these are Scotch broth and Cock-y-leeky, both, by the way, of Scotch extraction and perhaps one should say that Scotch cooks excel in them. All the same our use of vegetables in soups is not so universal as it might be. Apart from the flavour, vegetable soups are extremely nutritious and easily digested, so much so that the French and Belgians are accustomed to give an essence of leeks or onions, made by boiling down the vegetables in water, with salt to taste, in cases of gastric catarrh, influenza, severe cold and so on. They not only act as a mild antiseptic, but also are extremely nourishing.

The following recipes are all of soups such as the ordinary bourgeois on the Continent are accustomed to eat as everyday dishes. There is nothing elaborate about them; they are extremely easy to cook and are just as tasty—horrid word—and nourishing as the most elaborately prepared soup. In these recipes water is the only liquid mentioned, but they are all improved by using chicken consommé as a foundation. This is not so alarming as it seems, for "chicken" is a euphemism. Any old hen may be used for stock purposes or even an old game bird or rabbit, as long as it is fresh and has not been allowed to hang too long. Veal may also be used. Naturally, such a stock need not be made immediately before use: it will keep quite well for twenty-four hours even in hot weather, provided it is kept in a cool place. If stock is used, salt will have been added in its making, so salt should be added cautiously in the final preparation of the soup. The proportions are such as are required for four people.

1. POTAGE POIREAUX ET POMMES (Leek and Potato Soup).—Take three leeks and cut them in small pieces as for a julienne. Wash them thoroughly to remove all impurities. Peel 2lb. potatoes (floury for preference) and cut them in slices. Cook the leeks and potatoes with salt to taste, slowly in a saucepan in a quart and a half of water for two hours. Then pass the vegetables through a fine sieve. Add 2oz. butter just before serving.

2. POTAGE SANTE (Sorrel Soup).—2lb. of potatoes treated as above and same quantity of water and salt to taste. Cut one onion in very fine slices and chop fine ½lb. of sorrel. Cook the onion and sorrel with 2oz. of butter in a pan for ten minutes without letting them brown. Mix together with the potatoes, which are already cooking, and let them cook slowly for about an hour. After thoroughly cooking pass them through a sieve. Add one small teacupful of cream just before serving.

3. POTAGE CRESSONIERE (Watercress Soup.)—Same as above but with watercress instead of sorrel.

4. SOUPE AU CHOUX (Cabbage Soup).—Take one Savoy cabbage, 2lb. potatoes and one carrot; chop them in small pieces; wash well and place them in a saucepan with ½lb. of pickled pork. Let the mixture cook slowly for about three hours. Take out the pork and serve immediately. No salt need be added to this soup.

5. POTAGE PAYSANNE.—Cut up in small squares two carrots, two turnips, one onion and a few beans. To these add one lettuce cut very fine, and one teacupful of fresh peas. Put them in a saucepan with 3oz. of butter and let them cook gently for half an hour. Then add salt to taste and three pints of water and let the soup cook slowly for one and a half to two hours. Just before serving add a little butter and some chopped parsley and chervil. This soup is improved by adding small thin slices of stale bread at the moment of serving.

6. POTAGE PARMENTIER (Potato Soup).—Boil five floury potatoes in salted water. Drain them and pass them through a sieve. To the potato purée add a little butter, half teacupful of cream, salt, pepper and some chopped parsley and chervil. Add three pints of water or consommé and let it simmer for half an hour. Serve with croutons of fried bread. This soup is vastly improved by using consommé instead of water.

7. SOUPE A L'OIGNON (Onion Soup).—Take two medium-sized onions and slice them finely. Then fry the slices in butter until they are fairly well browned. Pour on to them three pints of boiling water and add a dessertspoonful of salt, and let the mixture simmer for a few minutes. At the bottom of the soup tureen place toasted slices of well crusted French bread and on the top of them sprinkle four tablespoonfuls of grated Gruyère cheese and two of Parmesan. Pour the soup on the top and serve immediately. This is for an ordinary onion soup for everyday use. If something with more body to it is required, stock should be used instead of water and a wineglassful of white wine can be added, but this should not be of a sweet variety.

These soups sound very simple, perhaps too simple for the ordinary cook, but they have been used and relished on the Continent for centuries and are all excellent. It will be noticed that they are composed entirely of vegetables, even in the thickening. For cream soups the thickening consists of what is called Roux Blanc (White Roux). This is made by melting on a slow fire a piece of butter the size of an egg and stirring in slowly a tablespoonful of flour. This is cooked for a few minutes, but not browned. Into it is poured a little milk or consommé; the cooking is continued until the roux thickens. It must be absolutely smooth and if inclined to be lumpy should be passed through a sieve. On the amount of roux added to the soup depends its consistency. A trial or two will soon show how much should be added for particular tastes.

8. CREME AUX TOMATES (Cream of Tomatoes).—Six tomatoes and one sliced onion are fried in butter for a few minutes. Three pints of consommé or water are added and the mixture is boiled slowly for three-quarters of an hour. After passing it through a fine sieve a cupful of roux is added, also a dessertspoonful of sugar and a trace of nutmeg. It is much improved if a cupful of cream is added just before serving. Tinned tomatoes are just as satisfactory, but in this case they do not require to be fried. Croutons of fried bread are served with this soup.

9. CREME SAINT-GERMAIN (Cream of Peas).—One and a half pints of shelled peas are cooked in water with one onion or shallot and with the knuckle-bone of a ham or some bacon with the rind on; the rind is necessary to give the very faintest smokey flavour, and also to keep the fat from melting too much and forming a scum on the top. The peas are then passed through a sieve. Consommé or milk should be added to form it into a consistency rather thinner than that of the finished soup. One cupful of roux is added and the mixture allowed to boil gently for twenty minutes. A dessertspoonful of sugar and a cupful of cream or milk is then added. Fried croutons are served with this soup.

10. CREME D'ASPERGES (Cream of Asparagus).—Three pints of consommé and one cupful of roux are cooked together for a few minutes with a few leaves of sorrel and chervil. To them is added a pint of asparagus purée made by passing well boiled asparagus through a sieve. Let the mixture simmer for a few minutes. Then remove the sorrel and chervil and add a cupful of cream before serving.

BEDDING OUT

NOW IS THE TIME TO COMPLETE YOUR BEDDING OUT PROGRAMME.

THE above heading will remind many readers of THE GARDEN that a very important work will, in a few days' time, call for attention, and upon the way in which it is carried out will depend, to a great extent, success or failure during the summer.

Thirty years ago carpet bedding was in extensive use. The formal designs in rich and subdued colours served a good purpose in those days, affording pleasure to all who favoured this form of bedding out. To-day, a less formal plan obtains; the beds of zonal pelargoniums, tuberous begonias and similar plants find much favour, and it is difficult to vary the matter of arrangement to any extent; but in the case of sub-tropical bedding and the combinations of dwarf and tall-growing plants in the same bed, very pleasing and charming effects can be obtained, and it is possible to have fresh combinations year after year. Many of these beds resemble groups for effect as seen in our conservatories a generation ago.

It is now too late to propagate more plants either from cuttings or seeds, but any shortage can be made up by purchasing plants ready to bed out. The cultivator should first decide on how the beds are to be filled and the number of plants required for each, then the extent of the stock in hand.

Every plant should be gradually hardened off to withstand full exposure in the open air. Some have already been placed out in groups, and many in frames, too, have been without the protection of the glass lights for a week or ten days. The next step is to space the plants farther apart, letting each one stand quite clear of its neighbour. Very careful watering is necessary; the soil in the pots and boxes should never be allowed to become dust-dry nor kept in a sodden state. In the southern counties it is safe to commence planting out the first week in June, beginning with the hardier subjects, such as zonal pelargoniums, fuchsias, marguerites, etc., and finishing with the more tender kinds, such as coleus, freesias, abutilons and begonias. The work may be completed by the middle of the month.

In the northern counties bedding-out should commence ten days later and be completed about the end of the third week in June.

It is not a difficult matter to get the soil in good condition for the reception of the plants where it is free of spring-flowering plants. Soil in good condition does not need the addition of much manure, a small quantity of well rotted dung and leaf-soil, mixed, will do splendidly in medium heavy soils and for plants that are required to produce handsome foliage. For those that are to be prominent as flowering specimens, scarcely any organic manures will be needed. For others that are to be regarded as low-growing and to be conspicuous as carpeting plants with richly coloured leaves, only a small quantity of rotted leaf-soil is desirable. The soil in beds occupied by spring-flowering plants will be more exhausted, and for every kind of summer-flowering plant some manure will be beneficial: applying larger or smaller quantities according to the kind of plant used, as referred to above. The spring-flowering plants needed for stock should be re-planted in nursery quarters that have been duly prepared for them.

BEGONIAS WITH SILVER-GREY CALOCEPHALUS.

A GOOD EXAMPLE OF THE [illegible] COLOURED FOLIAGE IN BEDS.

Light soils in showery weather are ideal for the reception of the plants at all hours of the day. Very dry ones in fine weather should be thoroughly soaked with clear water the day prior to planting and the plants should be watered forthwith, also an hour before they are turned out of the pots or boxes.

Naturally heavy clayey loams should be well broken up several days before any plants are to be placed in them. This action will allow them time to dry a little. To prevent soil adhering to the garden trowel or fork, rake the surface of each bed early on a fine day; the soil will dry up considerably in a short time, and the work of planting can be done much better.

Beds raised and with a rounded surface are ideal for plants if the soil is naturally tenacious of moisture. But in the case of light or sandy soils, perfectly flat surfaces are the most beneficial. It is always an advantage to take extra pains with the preparation of the soil, as the actual arrangement of the plants is so much more satisfactory.

All flowers and prominent flower buds should be removed from the plants

Digitized by Google

before they are planted, as the flowers help to exhaust the specimens and hinder the growth of young shoots which are to bear the summer display of blossom. Put out the plants just so far apart that they will, when at their best, completely fill the beds without any undue crowding.

Where the plants vary much in size it may be necessary to pinch off a few prominent shoots. The smallest plants, of course, should be arranged near the edge of each border.

The general height of the plants should be governed by the size of each border. Tall ones would look out of place in a small bed; half-standards, as dot plants, would be more suitable in the smaller, and full standards as dot plants in the larger borders. The very large borders should contain both standards and half-standards as dot plants.

Then there is the question of edgings. A narrow band of plants would look better as an edging to a small bed, and a broad, bold band as an edging to a large one.

Colour schemes are often troublesome to cultivators. Good effects may be created by having distinct colours in each bed with distinct edgings or a mixture of colours that harmonise. In some instances, beds of this description look best without any edgings. Dot plants should not be planted too closely together. The following are samples of suitable combinations: Fuchsias, Bougainvillæa glabra, swainsonias, plumbago, sweet-scented pelargoniums, Ricinus Gibsonii, eucalyptus, Dracæna indivisa, Grevillea robusta and abutilons.

All standard and half-standard specimens should be securely and neatly staked as soon as they are planted. Surface mulching is very beneficial; this also should be done directly the plants are put out. Rotted leaf-soil and garden soil, sifted and mixed, will answer, but coconut fibre is the best and presents a neat appearance.

Pure white flowers and silvery foliage create a too cold display. Rich purple and lilac colours agree together. Primrose, white and yellow, in this order, should exist close to purple and lilac; and scarlets, yellows and pinks should not be too close to them. There is room for more blue flowers in the gardens of both town and country. They harmonise well with dark or light coloured foliage. Associated with white, pale yellow or primrose coloured flowers, both pale and dark blues are delightful.

The following will be found effective combinations:

(1) Pelargonium Paul Crampel with a groundwork of Alyssum minimum and a bordering of Pyrethrum aureum.

(2) Standard heliotropes and fuchsias with a border of dwarf marigolds.

(3) Double-flowered marguerites, dot plants of Lobelia Queen Victoria and Iresine Herbstii forming a broad border.

(4) Brilliant salvias with a border of Pyrethrum aureum.

(5) Pelargonium Golden Harry Hieover mixed with blue lobelia, fuchsias as dot plants, Alyssum minimum as a broad border.

(6) Pelargonium Flower of Spring, Lobelia cardinalis or Queen Victoria, mixed with Pyrethrum aureum, as edging.

(7) The centre filled with Alyssum minimum, dot plants of fuchsias with very broad bands of Gazania splendens.

(8) In partial shade, funkias and fuchsias.

(9) Chrysanthemums, groundwork of Viola Blue Bell.

(10) Pelargonium Ivy-leaf "Galilee," Viola Blue Bell.

(11) Salpiglossis, mixed.

(12) A mixture of Fuchsia fulgens, Coleus Verschaffeltii, plumbago, (blue), and Ivy-leaved Pelargonium Madame Crousse.

(13) Ivy-leaved Pelargonium "Galilee," Viola lilacina.

(14) A mixture of Fuchsia Mrs. Marshal, Heliotrope President Garfield or Mme. Bussey.

(15) Celosias and liliums.

(16) Artemisia arborescens, Cassia corymbosa.

(17) A bed of sweet-scented plants is sure to afford unlimited pleasure. Both old and young plants may be associated in this case and quite large borders filled. Sweet-scented verbena (Aloysia citriodora), myrtles, heliotropes, Nicotiana affinis, musk, mignonette, Matthiola bicornis, scented-leaved geraniums such as citriodora, fragrans, Pretty Polly, carnations, liliums, and sweet peas. Rose beds may be filled with annuals, such as stocks and asters, effectively without any harm to the permanent occupants.

Dahlias, gladioli, chrysanthemums, hollyhocks, cannas and Michaelmas daisies look extremely effective judiciously used in newly planted shrubberies.

GEORGE GARNER.

SEMPERVIVUMS—A PRELIMINARY NOTE

BY DR. LLOYD PRAEGER.

> Reason, in itself confounded,
> Saw division grow together;
> To themselves yet either-neither,
> Simple were so well compounded
>
> That it cried, how true a twain
> Seemeth this concordant one!

THESE perplexing lines convey with tolerable correctness the prevailing opinion among gardeners concerning those interesting, useful, but distressing plants, the sempervivums. They look delightful, they will grow anywhere (if only it is dry), but—so goes the tradition—their nomenclature is hopeless, and their identity beyond the wit of man to determine. Nay more, they change their mortal frame by feat of magic mystery, like the shadowy (and shadowless) father of the Ladye of Branksome Tower, assuming different guises according to the soil and situation, and thus providing in the vegetable kingdom a parallel to the transmutation of metals, long believed in by the alchemists, and now triumphantly and unexpectedly proved by modern science to be true.

But the sempervivums are not quite so black as they are painted. The transmutation legend may be at once dismissed. It arose chiefly from the fact that the houseleeks, like all the people who dwell in dry places, take care to conserve their water supply. When threatened with drought, the leaves curl inwards and enclose the growing point. This may cause the rosette to look very different from when it is expanded, especially since the back of the leaves is often of different colour and sometimes of different texture from the face. Accordingly, rosettes growing on a dry stone may have a different size, shape and colour from their fellows which have fallen down and are flourishing in damp half shade below. But in an admittedly difficult genus like sempervivum, where a quite unusual similarity of form pervades all the species, we cannot hope to be able to rely on mere general appearance for their discrimination. We must look closer. Size, shape and colour of leaf count for a good deal, but much more important is the distribution of hairs, both on the margin and on the upper and lower faces, and the characters of these hairs. We need to detach a full grown, but not too old leaf carefully at its base and to study all its features, for which purpose a low-power lens is essential. We shall find that the magnified leaf shows features the existence of which we had not suspected, often characteristic and frequently beautiful. The leaf of the common S. montanum, for instance, is densely covered, front, back and edges, with a forest of slender hairs, each tipped with a tiny globular gland. S. Tectorum in all its forms, on the other hand, is quite devoid of hairs save on the margins, where there are strong, tapering, semi-transparent, tooth-like ciliæ set in a close row. The geometrical cobwebby white hairyness of the arachnoideum group, again, takes on a new beauty and significance under the lens, as do also the fleecy tufts with which the leaf tips of a number of other forms, including many of the arachnoideum hybrids, are clothed.

We shall find that these critical characters remain, whatever be the situation, and light as to the true affinities of our plants will begin to dawn. Then, of course, everything connected with the flowering shoot and flowers is of equal or greater importance, and in the case of closely allied species is essential for purposes of identification; but so far as my observations have gone, most of the species can be named from the barren rosettes alone, with the aid of experience and a magnifying glass.

How many species have we to deal with among the hardy sempervivums? The evidence is most contradictory. If we take the Kew Hand-List of Herbaceous Plants we find no

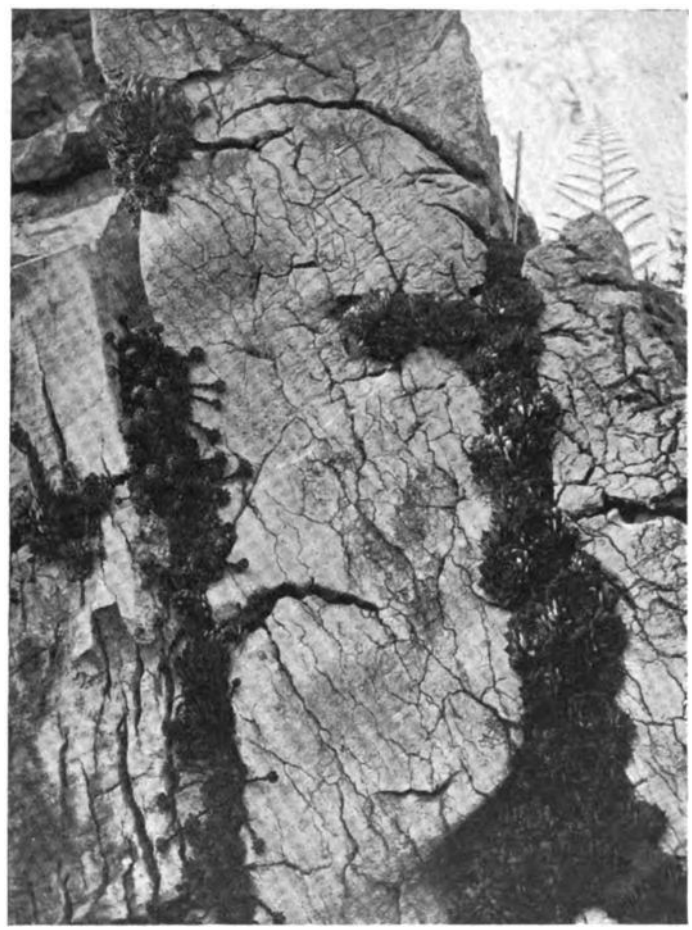
Digitized by Google

fewer than fifty-three specific names, of which six are italicised as being synonyms of the remainder. All but one or two of these are European plants, found on mountains from the Pyrenees to the Caucasus. Yet if we turn up the latest account of the flora of the whole region of the Alps, which forms the headquarters of the genus in Europe (Hege's "Illustrierte Flora von Mittel-Europa"), we find only eleven species admitted; while Koch's standard work on the Central European flora enumerates thirty-eight species for Switzerland and Germany alone! Such contradictory figures simply mean that there has been a great difference of opinion among botanists as to what constitutes a species among these perplexing plants. It also signifies that the same species has often been given different names by botanists working in different places and at different times.

This lamentable plurality of names is especially concentrated round that commonest and most variable of all the houseleeks, S. Tectorum. To this plant in its various forms, at least sixty names are attached, not more than a dozen of which—if so many—deserve to be retained even as varietal appellations, if we adopt the same standard that is usually employed for other plants. Rouy and Camus, who in their "Flore de France" take S. Tectorum very seriously, describe forty-three sub-species, forms and varieties of that species for France alone. But the French botanists attach more importance to the minor variations of plants than has usually been the case among English workers—perhaps to our own loss.

In gardens, of course, the reigning confusion is intensified, for here the names known to botanists, to which published descriptions are attached, are augmented by many others derived from heaven knows where: in some cases the gifts of enthusiastic but misguided amateurs, in other cases the result of errors of transcription and so on. The nurseryman likes a new name, and so these foundlings wander out into the world. In the end, a state of confusion ensues which is past belief. I have had occasion lately to go through a number of large English collections of sempervivums. Several consisted of a hundred or more plants all bearing different specific names. In some cases half of the total consisted of S. Tectorum in slightly different forms. In no case did the hundred or more plants represent more than twenty species; in some cases not more than a dozen!

Of course, it is admitted that some of the species vary a good deal, and varietal names may well be bestowed on the most marked departures from type. Also, hybridisation is common, both in nature and under cultivation, and the presence of these hybrid forms renders the task of disentangling the true species much more difficult. But the genus is sadly overburdened with superfluous nomenclature. In the whole of Europe—to which area the true sempervivums are confined—there are certainly not more than forty plants which can rank as species, in the usual application of that term. These forty species boast about 200 specific names. Probably another forty or less are worth distinguishing as varieties, at least for horticultural purposes, and the number of recognised hybrids is about the same.



SEMPERVIVUMS ON A GRANITE CRAG IN THE GENEVA BOTANIC GARDENS.

As has been said, it is the presence of these varieties and hybrids that makes it so difficult to identify the sempervivums of our gardens. The hybrids are not even in many cases straightforward first crosses between species, but themselves interbreed and crossed with the parents and even with other species. So we may have a Tectorum with just a trace of Wulfeni, or a montanum which is one quarter arachnoideum. Or we have forms like the well known but mysterious S. Funckii, for which the best European authority on sempervivums suggests the parentage arachnoideum var. doellianum × montanum sub-sp. stiriacum × tectorum f.—an appalling family tree! When it comes to this kind of thing, it becomes essential to study the plants in their native state. Anywhere along the range of the Alps one may do this, and once one has got into one's head a clear idea of the parent species, then the study of the intermediates becomes less difficult and very interesting. But to understand them thoroughly one must bring them home and grow them, so that one may observe them at all periods of growth.

From Switzerland last summer I brought back some 200 gatherings, representing the collective sempervivum flora of twenty to thirty separate localities, the set from each locality being kept together. Although only four species are represented—arachnoideum, montanum, Tectorum and Wulfeni—hardly two of the 200 plants look exactly alike. Since the possible parents present in each locality are known, it should not be impossible to decide the parentage, even when somewhat complicated, of the intermediate forms; some of them, indeed, can be analysed at a glance; and I think that with this as a basis on which to work, the sempervivums of the Central Alps will not appear quite so bewildering. In subsequent numbers I hope to be able to give some definite notes on these species and their hybrids.

As we go eastward from Switzerland the sempervivum flora changes. Most of the familiar plants dwindle out, and in their place we get a new set of forms. Some of the Austrian species, such as S. Pittonii, are very distinct and quite easily recognised; but in the Balkans, especially in Bulgaria, there are a good many which are as yet but little known. These Bulgarian representatives are often finely hairy and also yellow-flowered—a tint rarely seen among the Swiss species; they appear to occur to a great extent in separate areas, and from this one may hope that hybridisation is not so prevalent as in the Alps, and that one will not be confronted, as in some of the Swiss valleys, with several species and a multutidinous and complicated joint progeny extending to the *n*th generation.

FORTHCOMING EVENTS.

June 7.—Blackburn Horticultural Society's Meeting—Darwen and District Agricultural Association's Annual Show.

June 9.—United Horticultural Benefit and Provident Society's Meeting.

June 10.—Jersey Gardeners' Society's Meeting.

June 11.—Royal Horticultural Society's Fortnightly Meeting (two days). Lecture on the first day at 4 p.m. by Mr. E. A. Bowles, M.A., on "Uncommon and Interesting Plants."

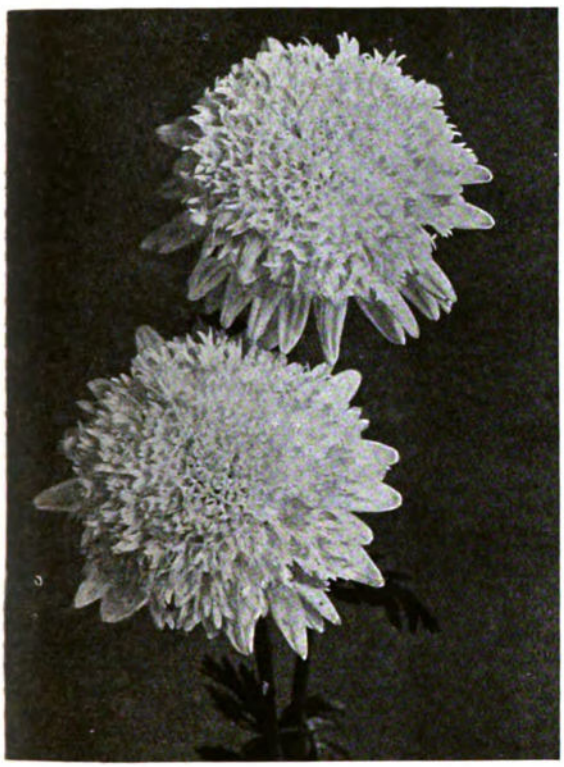
MORE ABOUT THE CHELSEA SHOW

THIS IS THE SECOND AND FINAL PORTION OF THE REPORT ON THE CHELSEA SHOW, OF WHICH THE FIRST INSTALMENT APPEARED IN OUR RECORD NUMBER LAST WEEK.

HARDY FLOWERS

(*Continued from page* 282).

A sort of horseshoe border, comprising gladioli, trolliuses, lavateras, primulas, irises, peonies, violas, alpine phlox, statice,



ONE OF MESSRS. KELWAY'S PYRETHRUMS, AS SHOWN ON THEIR CHELSEA STAND.

Cineraria maritima, Incarvillea Delavayi and other hardy plants made a welcome change as an exhibit, as arranged by the Maytham Gardens. The grass border and pathway between added very materially to the picture. This was to be seen at the Hospital entrace to No. 2 tent.

Another novel group in the same quarter was arranged by Mr. Thos. Carlile, and embraced such plants as geums, lupins, pyrethrums, wallflowers, verbascums, irises, perennial candytuft, Viola purpurea and numerous other plants. It was a grand mass and had many admirers. Near the same spot was a splendid exhibit of hardy flowers shown by Messrs. Maurice Prichard and Sons. Here were to be seen Oriental poppies and beautiful variety lupins, eremuri, pyrethrums, aquilegias, heucheras, geums, armerias, trolliuses, genistas, verbascums, white broom, irises, and a great host of beautiful things which want of space forbids us mentioning; it was a fine effort.

A dainty little circular group at the Hospital entrance to No. 1 tent was arranged by Messrs. G. Gibson and Co. The exhibitors showed Trollius Triumph, T. Fire Globe, T. Aberdonian, T. asiaticus, T. Mrs. G. Gibson, T. Lemon Queen, and other varieties, all very good. Also Giant Orange Iceland poppy, Daphne Cneorum, heuchera, Primula pulverulenta, saxifraga and other interesting plants.

An extremely elegant and artistic group of aquilegias came from Mr. V. C. Vickers (gardener, Mr. W. Watkins). The plants were well grown and bore in profusion spurred blossoms of the most dainty description, the colours being charmingly diverse.

A raised garden in tent No. 1, on which were arranged by Messrs. Bakers, Limited, beds of hardy flowers, flowering shrubs, acers, etc., together with hardy flowers of a varied description, made a beautiful exhibit. Delphiniums, heucheras, lupins, trolliuses, irises, aquilegias, spiræas, primulas and other plants combined to make a fine display.

A grand exhibit in No. 1 tent was set up by Messrs. Bees, Limited. Here was to be seen a plethora of beautiful things, such as lupins (varieties Delight and Sunshine), Campanula Telham Beauty, aquilegias in great variety, single pyrethrums, Meconopsis cambrica plena, geums, verbascums, acers and numerous other useful plants in the hardy flower garden.

In Messrs. Barr and Sons' group of tulips, irises, etc., there were many such things as peonies, aquilegias, lupins in variety and many dainty plants, all worthy of notice.

Messrs. R. H. Bath, Limited, had as a finish to their group of tulips, hardy plants, such as trolliuses and beautiful blue and white native hyacinths.

A very gay exhibit was that put up by Messrs. Harkness and Sons. Showy Iceland poppies in primrose, orange and yellow shades were very fine. So, too, were Polemonium Richardsoni, Trollius Orange Globe, heucheras, single and double pyrethrums, Viola cornuta purpurea, fancy pansies and other plants.

The delphiniums shown by Messrs. Hewitts had much to commend them. Tall and stately spikes of blossoms represented such varieties as Sister Clare, Mrs. Townley Parker (pale blue), Joy Bells (rich mauve), Smoke of War (deep mauve and blue), Mrs. Colin Macever (mauve and blue), Blue Boy (rich blue), Queen Mary (pale blue and white) and many others.

PINKS & ALLWOODII

Pinks, as exhibited nowadays (apart from the many beautiful alpine species of dianthus and their hybrids, which may best be described with other rock garden plants), are—if the Hibernian touch may be forgiven—either Herbertii or Allwoodii. Allwoodii look like pinks but have carnation "blood"; Herbertii resemble compact-habited carnations and are, to the best of their raiser's knowledge, pure-bred pinks.

Opposite their great bank of carnations, Messrs. Allwood staged a veritable garden of Allwoodii and the very real progress which they are making with the flower was more evident than ever. This year's novelties include the clear salmon-pink Elizabeth, a shapely flower and very free; Beatrice, deep salmon rose and, as massed, extremely effective; and Bryan, which is of the shade of pink we associate with Enchantress carnation and very full and carnation-like in appearance.

For the rest, the following attracted our attention, but many visitors will prefer an entirely different set:—Sybil, one of last year's novelties, improves on acquaintance—she is semi-single (a delightful condition!), soft pink, shapely and beautiful; Matty, rose pink, eyed maroon, may be described as an improved Rufus; Alfred, a splendid white, as an improved Harold—it is of much better habit; while another semi-single one, Dickon, attracts by reason of the large and

A GROUP OF MESSRS. ALLWOOD'S NEW VARIETIES OF ALLWOODII.

Digitized by Google

conspicuous dark maroon eye to the bright rose shapely blossoms; Jenny is a delightful clear pale pink; Hugh, magenta-purple, is fine with its brilliant but quarrelsome colour; Barbara is as near true crimson as one can expect in a pink or near-pink. Another brand new one—Edith—attracts by reason of a distinct picotee edge, but is otherwise susceptible of improvement.

One could hardly miss Messrs. Allwood's garden of pinks, but, unless they specially looked out for it, many visitors will have missed Mr. C. H. Herbert's short length of tabling, on which were displayed his well known Dianthus Herbertii. A few of the very best on view were Bridesmaid, "Enchantress" pink, zoned deeper, very large, light, graceful and shapely; Mrs. C. H. Herbert, of similar form, but rose pink, zoned crimson-maroon; Mrs. Giffard Woolley, of similar colouring to Bridesmaid, but larger, fuller and quite distinct; the bright rose-pink May Queen, now well known, but in splendid form; Fire King, shapely and almost pure vermilion; Victory, black-crimson and more fragrant even than its delightfully scented neighbours; Prince of Wales, salmon; Lord Lambourne, crimson lake; Red Indian, purplish rose; and last, but certainly not least, Model, doubtless the most perfectly formed pink ever raised. Several good laced pinks were also on show.

Messrs. Andrew Ireland and Hitchcock made a brave splash of colour with their brilliant rose carnation-sweet william hybrid, Mascott's Dianthus.

DAHLIAS

A pretty table group, mostly of the star dahlias, was shown by Messrs. J. Cheal and Sons, Limited. The better star dahlias were White Star, Dorking Star (rich pink), Gatton Star (scarlet), Mauve Star (mauve-pink), Crimson Star (brilliant) and Primrose Star. There were many other representatives of this beautiful section. A fine decorative collarette named Novelty is a good brilliant scarlet with golden collar. There were other types of these showy flowers to be seen in this collection.

Dahlia (Single) Coltness Gem, a crimson sort, was shown by Mr. John Forbes. This is a valuable plant for the garden.

A unique group of dahlias of all types was shown by Messrs. Carter Page and Co., in tent No. 1. These showy plants were represented in diverse form and colour and gave an excellent idea of their value in the garden. Here were to be seen collarette, decorative, peony-flowered, single, camellia-flowered and the beautiful miniature peony-flowered sorts, all very showy and attractive. This was a splendid effort and did the exhibitors great credit.

GLADIOLI

This flower did not figure extensively at the Show. Messrs. Hewitt and Co. had two large varieties, Catherina and Brimstone, a very good combination, and the primulinus was represented by the popular favourite, Maiden's Blush, and that ever attractive Orange Brilliant. Messrs. Wallace and Co. had a few of the Nanus section, including Peach Blossom and Delicatissima. The Maytham Gardens showed the only novelties we noticed, in four varieties of the new race of Herald Gladiolus. Joost van Vondel, a scarlet with white blotch, and P. C. Hooft, a salmon orange, with white blotch. There is a slight violet tinge in both these flowers between the white and main colour of the flowers. These two were introduced from Holland two or three years ago. They do not go well together, but seen apart they form good pot plants for the conservatory. Two of later introduction are Erasmus and Leeunwenhoek, the former a pale pink and the latter a salmon rose with large white blotch. This variety also shows more plainly the Nanus blood, both in the bloom and foliage. Potted up in November and given the protection of a frame they will come into bloom just after the Nanus section.

VIOLAS AND PANSIES

Violas were exhibited by Mr. H. Clarke, who had many beautiful sorts in his collection, several of which were of exhibition character. Good bedding sorts were Oxhill Purple, Gladys Finlay, White Empress, Mrs. Chichester, Maggie Mott, Primrose Dame, Admiration, John Quarton, Bridal Morn, James Pilling and Moseley Perfection. The exhibition sorts were better seen in Master Banks, Drummer Wilson, Donald McDonald, Mrs. A. Stevenson, Mrs. J. MacEwan, Rebecca, Lady Knox and Mrs. W. R. Milligan. Violas and a few fancy pansies were shown in grand form by Mr. F. J. Bell, but, unfortunately, in the old method of sprays, which is against the best interests of these plants. Of the violas the better sorts appeared to be Mrs. Jamieson, Edward Bell, Annie Hamilton, Mrs. F. J. Bell, Maud Bell, Willie Stevenson, Mrs. J. Ritchie, Orange Perfection and Miss Fisher. The fancy pansies are not very attractive, although they are interesting.

A large and comprehensive display of violas was made by Mr. William Yandell. They were arranged in tins and pans in sand, associated with viola foliage, and gave the idea that the plants were growing. The more noteworthy varieties were Moseley Perfection, Primrose Dame, Admiration, Blue Bedder, Handsworth Perfection, W. H. Woodgate, Edina, Fred Williams, Mauve Queen, Master Banks, J. V. Macdonald, Maggie Mott, Archibald Grant and Mrs. Chichester. There were also several varieties of Viola gracilis.

Messrs. Jarman and Co. exhibited a number of baskets of Viola gracilis in varieties and some of the better garden violas. The better forms of the former species were Purple Robe, Compacta, Wyndley Gem, Gold Crest, Moonlight, Violet Queen, Golden Spur, Butterfly and Heavenly Blue.

Bowls of violas were shown by Mr. John Forbes, including such sorts as Perdita, The Mearns, Blanche, Miss Fisher, Moseley Perfection, Maggie Mott and Mrs. Chichester.

Messrs. Carter Page and Co. had as an edging to their dahlia group a large number of the better violas in good form and condition. Such sorts as Moseley Perfection, Maggie Mott, W. H. Woodgate, Mrs. Chichester, Swan, Mrs. Marrison, John Quarton and many other sorts were splendidly represented.

TULIPS

Flora's summing up when all the flowers had appeared before her and pleaded their cause hits off the Chelsea Show of 1924 to a T.

> "I in all this num'rous throng must own
> I see no head but what deserves a crown,
> On what one flower can I bestow my voice,
> Where equal merits so distract my choice."
>
> (*Cowley, Of Plants, Book IV.*)

Tulips, even in this very trying year, contributed their quota to Flora's commonwealth, as a visit to the various exhibits in which there were tulips proved. The most extensive and varied was that of Messrs. Barr and Sons. Here were the magnificent scarlet Marksman and the new dainty pale yellow Honeymoon; Zomersshoon the Ancient rubbed shoulders with another "rose," Striped Flag—both examples of what are known among tulip people as rectified flowers. The rich deep scarlet-crimson Sprengeri, with its yellow anthers represented the species. The deep plum-violet Bacchus and Golden Bronze were typical of the old Dutch breeders or selfs, and so on and so on. Messrs. Dobbie and Co. had a wonderfully clean exhibit for this disastrous year. They were not those tremendous blooms which the firm in the past has accustomed us to, but they were none the worse for that. Ordinary people can grow tulips with the self same result. Orange Perfection is a pretty shade of salmon flushed with orange. Then there were the dark blood red Eclipse, the pure white Cottage Carrara, the rich deep yellow Avis Kennicott, the dark Faust, and Prince Charming, which might well be styled the prince of tulips for cutting. Messrs. R. H. Bath had many novelties in their exhibit which have never before been seen in England. Some were under numbers, but "Oranges and Lemons" and Sundew have been named. This last variety was certainly *the* tulip novelty of the Show. It is a medium sized red with all the edges of the petals to a depth of an eighth of an inch or so armed with excrescences which suggest the tentacles of the fly-devouring Sundew. Oranges and Lemons is a sort of "cottage" Cottage Boy, with the two colours strongly differentiated. Both these have been raised in Holland. Messrs. Ernest Paul and Co. were new exhibitors. They had a lot of well grown stuff, including the old favourite The Fawn and a very fine example of Louis XIV. Eclipse and Honeymoon were both very good here. The Welsh Bulb Fields can grow tulips and there was an excellent exhibit of their produce. Their La Merveille, Lord Cochrane (lake brown) Goldfinder (scarlet with pure yellow base), Amber (pale buff and rosy apricot), and Ida Scott (a violet-mauve with a white base) were all A 1. Someone once described the weather-spotted tulips as tulips with the measles. The Welsh flowers had fortunately escaped the visitation. There was a beautiful specimen of Prince Charming and a splendid vase of Prince of Orange. Messrs. Artindale and Son had an irregularly shaped group of ordinary varieties on the ground. Among them were Europe, Pride of Haarlem, Margaret and Viking. Odd "species" tulips cropped up here and there as, for example, Persica in Mr. Maurice Prichard's and Messrs. Gavin Jones and Ingwersen's rock plant displays. They did well to call attention to its at-homeness in such surroundings. Messrs. Hewitt and Co. had a nice little selection in which were included Boadicea, Zulu, Baronne de la Tonnaye and Beauty of Bath. There may have been odd vases in mixed groups here and there, but the burden of the tulip was borne by the firms whose names have been mentioned. Visitors will have seen for themselves they have earned a creditable place for this most famous flower in Flora's Commonwealth at Chelsea, in the year of our Lord, 1924.

FRUITS & VEGETABLES

A large collection of fruit trees in pots was shown by Messrs. T. Rivers and Son, Limited. Here were to be seen peaches, nectarines, plums, oranges and lemons. The trees were heavily laden and the fruits of excellent colour. The accompanying illustration shows the fruiting capabilities of the lemon tree.

A magnificent exhibit of apples was that by Messrs. George Bunyard and Co., the fruits being tastefully displayed in baskets.

Digitized by Google

A FINE TREE OF IMPERIAL LEMONS ON MESSRS. RIVERS'S STAND.

Notable varieties were Cox's Orange Pippin, Wellington, Allen's Everlasting, New Bess Pool, Blenheim Orange, Chatley's Kernel, Calville, Malingre, Lane's Prince Albert, Sir John Thornycroft, Aromatic Russet and Old Royal Russet. The fruits were of very fine colour and form. There is no secret regarding their storage, Messrs. Bunyards simply wrap each fruit in a piece of paper and store in a cool building. This exhibit created a great deal of attention and many visitors were amazed at seeing fruits in such perfect condition. It is really quite simple to store apples if a little care and forethought are exercised. Sound specimens, careful handling and a dry, cool storeroom are the essentials of successful storage.

A very tempting display of strawberries was shown by Messrs. Laxton Brothers. Their new variety Tit-bit is of good colour, size and flavour. Here, too, were Laxton's Majestic, a good cropper and of excellent flavour; Lord Beatty, an ideal main crop variety; Victory, The Duke and Abundance.

Mrs. Delmé-Redcliffe had two dishes of strawberries. These were not named. The fruits were of good size and colour.

A wonderful collection of vegetables came from the gardens of the Hon. Vicary Gibbs. The exhibit was excellent in every way, and Mr. Edwin Beckett is to be congratulated for his skill in producing such high-class vegetables. Here were radishes, (including Forcing White Olive), marrows, peas, turnips, cucumbers, broccoli, tomatoes, kohl rabi, lettuces, mushrooms, celery—but why enumerate? It would be difficult to find a vegetable that was not represented.

Several dishes of fine potatoes were shown by Messrs. Dobbie and Co. Such sorts as Tinwald Perfection (late), Arran Chief (maincrop), Majestic (early maincrop), Di-Vernon (early) and Midlothian Early were to be seen. The tubers were in excellent condition. There were also potato plants in pots.

HARDY PRIMULAS

Among the *cognoscenti* to think of hardy primulas is to envisage Dr. Macwatt. We remember that the worthy Doctor threatened that last "Chelsea" would record his absolutely last appearance with his favourites "on the London boards," but visitors had yet another opportunity of making the acquaintance of most of the really choice primula species at present in cultivation. Among the bold masses of alpine, show and border auriculas, many gems were worthy of note.

The golden Primula Forrestii, of which so much was hoped, but which will, alas! never be a good garden plant, was here. So were several of the sikkimensis clan, including the type species, P. pseudo-sikkimensis (of more slender build), P. flexilipes more slender still and the bells rather up-tilted), P. bi-serrata (tiny, small-umbelled and deeper in colouring), and the purple secundiflora. Whole colonies were set up belonging to the involved muscarioides set, but where Dr. Macwatt hesitated to commit himself, we shall not venture to particularise further than to say that conica and deflexa types were in evidence.

P. Sino-listeri, of the obconica clan; PP. Veitchii (in excellent form) and lichiangensis of the cortusoides set; PP. chionantha and sino-purpurea of the nivalis group—the former a very robust species; and P. anisodora, which we omitted to smell, but which has handsome foliage and quite ineffective tiers of brownish-crimson flowers, called for notice. Other uncommon ones included PP. Parryi (well known, but still rare), seclusa nutans (handsome, though not in flower), florida (a quite tiny purple kind), erythrocarpa (of the denticulata set, but not at all "cabbagy"), and pulchelloides (rosy-mauve—more rare than beautiful).

The rather work-a-day P. involucrata was interesting as being one of a small group of very nearly allied species and Dr. Macwatt had, in addition to the typical creamy form, one of quite bright but pale lavender colouring, which has curiously mottled foliage, but otherwise comes near some of the forms of P. sibirica (also shown). Many consider P. Wardii only a form of P. sibirica, but a plant of the true species—unfortunately not in flower—showed the foliage to be very distinct.

Dr. Macwatt's exhibit inspected, the primula fancier had to wander far in the big tent, content if he found a little group of treasures here and there among more general exhibits. Mr. Allgrove had bold groups of that best of Candelabra primulas, P. pulverulenta, and even finer masses of its delicate pink form—the sensation of the Great International Exhibition in 1912—Mrs. R. V. Berkeley. Having feasted our eyes on this mealy loveliness, we made our way to Mr. Dalrymple's pink pulverulentas (staged by Messrs. M. Prichard) and noted the added and beautiful range of colouring. A very interesting article might be written about these pink forms of P. pulverulenta. Messrs. Maurice Prichard themselves set up in a very choice and cunning exhibit of alpines, that brightest of the Cockburniana-pulverulenta hybrids—Red Hugh, as well as PP. sikkimensis, japonica and Veitchii. Messrs. Gavin Jones and Ingwerson had a delightful little group of the muscari-like P. deflexa and that strongest of the "birds'-eyes," P. frondosa. Primula Lissadell hybrid and the more upstanding, but fewer flowered Unique were everywhere, but P. Beesiana was only found in Messrs. Wallace's lily garden, where they also had some nice plants of muscarioides, including a pretty pink one. Messrs. Prichard and Co. (the West Moors firm) had P. pulverulenta, Messrs. Wells and Co., frondosa and luteola, Messrs. Waterer, Sons and Crisp, Veitchii, and Messrs. Carter Page several vigorous kinds, but what has become of that golden giant, helodoxa—we did not find a plant of it, though Messrs. Oliver and Hunter had a delightful colony of the giant form of P. Littoniana.

ROCK PLANTS

The steadily growing popularity of rock plants was well served at Chelsea by an increase in the number of exhibitors and the general high standard and variety of the plants shown. If there were comparatively few absolutely new introductions there were a great many valuable new varieties and improved forms of plants in general cultivation, and a large number of plants still seldom seen in gardens but appealing for more general recognition.

DR. MACWATT'S PRIMULAS.

Digitized by Google

The little indoor rock gardens seemed more than usually brilliant this year; they are frankly *jardins de fantaisie*, and, bound by no strict rules of cultural propriety, are full of fascinating and amusing combinations that no permanent garden could ever show. Calcifuge and calcicola forget their differences, rampant trailers associate on terms of paradisal equality with the most diffident high alpines, and woodlanders and shade lovers flourish side by side; the general effect has the inconsequent beauty of a dream, and no one will be unreasonable enough to carp at its unrealisability.

It was interesting, after a general look round, to measure the popularity of some plants of fairly recent introduction. Wahlenbergia serpyllifolia, especially the sumptuous major form that is said to have originated in the garden at Ingleborough, is evidently widely appreciated; and, for the alpine lawn and moraine, the three little Balkan pinks, Dianthus microlepis, Rumelicus and Musalæ (the last received an award of merit among the new plants). The biennial habit of Meconopsis Prattii does not prevent it from being popular, and there seems every possibility that this magnificent group will soon be more generally grown. Meconopsis pseudo-integrifolia, an enormous pale sulphur-yellow, and M. primulina in silky violet-purple (shown by Mr. A. K. Bulley) were put in the cage with the new plants and looked like prisoners convicted of undue brilliance in some horticultural Erewhon.

One of the largest and most interesting miniature gardens was that of Messrs. Tucker and Sons, a little cliff shelving down to patches of alpine lawn made up of Ranunculus alpestris, Dianthus microlepis, Phlox Douglasii, etc., with several flourishing flowering plants of Gentiana bavarica. At one end a subtle and delicately coloured group was composed with old double rocket (so seldom seen in southern gardens), a pure cold white occasionally flushed with lavender, against a crushed strawberry hybrid mullein (Verbascum Cotsall Queen) and the pale tea rose colouring of Lilium regale.

The centre of interest in Clarence Elliott's indoor exhibit was a magnificent group of Aquilegia glandulosa, squired by the modest Aquilegia ecalcarata in dusty purple, in a grove of dwarf conifers. In the foreground a plant of Geranium Farreri, pale apple blossom pink with black anthers, and the general appearance of a refined and better coloured G. Pylzowianum, of which it was at first thought to be a high alpine form. Shown by Mr. A. K. Bulley, it received an award of merit, but it was afterwards found to have been previously decorated as G. Donardii. Another very attractive plant, recently introduced, was Wahlenbergia serpyllifolia Malby's White, not a negative albino, but a distinguished form with narrow lines of violet on the ridges of the corolla. Malby's Amethyst is similar, but the ground colour is pale purple.. Several good specimens were shown of a rare native, the little Burnt Orchid (Orchis ustulata), of which the greyish lavender, faintly flushed with pink, and purple-black buds, combine into the rather remote suggestion of a burnt stick.

Messrs. Maurice Prichard and Sons made a miniature rock garden of cliff and stream, with various forms of Papaver alpinum looking very much at home in a patch of scree. A large group of pink Sedum pilosum made a pleasant picture with the grey and white of achillea. An unusual plant was Malvastrum Monroeanum, a flopping trailer with saucers of a curious dull cherry-red, but probably only hardy enough for a dry wall in a mild district.

Messrs. Frederick Wood, having made a demonstration of colour with mimulus hybrids of their and the impermanent scarlet chamædryoides, achieved a quieter effect with a pale French grey form of Veronica gentianoides and the hybrid Heuchera tiarelloides. They also showed a small pavement planted with Thymus Herba Baronæ, Menthella Requieni, Mazus rugosus and Linaria pallida alba.

Amos Perry showed a rare jewel in Nomocharis pardanthina Farreri, a lily flower in pale shell pink with a circle of light purple-brown freckles at the base of the petals round a ring of pale green, and a green style rising out of a black furry centre. This is one of the last of the late Mr. Farrer's introductions, and if it proves tractable in cultivation it may well be one of the finest.

Messrs. Skelton and Kirby showed a bold grouping of Delphinium nudicaule, azalea and Aquilea jucunda, also a neat form of Dianthus cæsius of their own raising.

Mr. W. Wells, jun., showed Primula luteola and an effective group of the smoky pink seed heads of Geum montanum.

Messrs. Cheal showed well grown specimens of Lewisia Howelli and Ourisia coccinea, also a particularly good form of Geranium cinereum, a pure pale pink, delicately and regularly veined.

Messrs. Reuthe, as usual, brought a large number of rare and curious plants. The curious Phyteuma comosum with fantastic horns of blown glass, a sinister codonopsis (ramondioides) with large dark hairy leaves, Androsace spinulifera and the very beautiful pink form of Ramondia pyrenaica. A very rare native is the little Cornus suecica, with cool "woodland" flowers in black and white.

Messrs. Laird and Dickson's exhibit was exceptionally well spaced showing the individual plants to great advantage, appreciated by Meconopsis brevistyla (pale sulphur-yellow) and M. rudis in rather steely blue.

Messrs. Maxwell and Beale showed Potentilla nitida in the white and dark carmine form (atrorubens), the curious and tender Lavendula stoechas, and the new hybrid Dryas Sundermanni, of which the straw yellow, acquired from the American D. Drummondi, scarcely compensates for the loss of the grace and neatness of D. octopetala, its other parent.

Mr. H. Helmsley gained an award of merit for a deep, rich blue variety of Linum narbonnense, slightly flushed with violet, an interesting break from the type.

Messrs. Gavin Jones and Ingwersen showed Saxifraga caterhamensis, a fine silver saxifrage with a dense ring of carmine spots, but not very different from MacNabiana; also a good form of Arenaria montana with large and regular petals.

Messrs. Rogers showed Cupressus tetragona cæspitosa and minima, minute mossy conifers of their own raising and good specimens of Haberlea Fernandi Coburgi.

Messrs. Prichard and Co. showed a collection in pots which included an attractive dwarf form of Veronica pimeloides, a small flat-topped shrublet flowering freely, and a semi-double form of Lithospermum prostratum, blotched blue and white (Prichard's Variety), which is hardly an improvement on the type.

Messrs. John Waterer, Son and Crisp showed fine plants of the white sweet-scented Daphne caucasica, an improvement on D. alpina and said to be of at least equally easy culture. Potentilla Farreri in bright yellow made a pleasant combination with the shrubby Pentstemon Bridgei. The quaint little water violet Erpetion reniforme was a welcome and seldom seen stranger.

The collection of Messrs. Bowell and Skarratt was exceptionally rich in hardy terrestrial orchids. Orchis papillionacea, from Italy, is an especially fine species, seldom met with in gardens, with a broad labellum netted like an onco-cyclus iris in mauve and lilac. It seems a pity that this attractive group is not more widely grown. Viola pedata, with its thrown-back upper petals giving it a curious sulky look (only too often borne out in cultivation), was shown in its two forms, the pale lilac type and the fantastic but less pleasing bicolor variety. The white form of Polygonum viviparum, a tiny furry spike of dead white, is a choice and curious little plant for good company, and several vigorous little plants of it were shown.

Messrs. E. Staplehorn showed a large group of the rare Silene Hookeri, probably the finest of all the silenes with its relatively enormous, deeply divided petals of pure rosy pink.

Messrs. Oliver and Hunter showed fine specimens of Meconopsis nepalensis and Prattii, with the trailing pink Viola bosniaca, the true Aquilegia alpina and Omphalodes Luciliæ.

STOVE AND GREENHOUSE PLANTS

Messrs. Sutton and Sons again excelled with these. Towards the centre of tent No. 1 this firm arranged an exhibit of plants grown under glass, comprising many of the best greenhouse flowers as well as beautiful half-hardy and hardy annuals. This exhibit was arranged in the form of a Maltese cross, and included in the display were no fewer than sixty-one distinct groups of different plants. Especially noteworthy among them were grand examples of Clerodendron Fallax, tuberous-rooted and other begonias, cinerarias, superb examples of herbaceous calceolarias, gloxinias beautifully marked, Primula obconica, beautiful streptocarpuses and numerous other plants. There were also, in excellent form and condition, Phlox Drummondii, salpiglossis, schizanthus, viscaria, clarkias, lobelia and a host of charming plants far too numerous to mention. The different groups were arranged most effectively.

Another especially noteworthy exhibit was set up by Mr. H. J. Jones. This was to be seen in a very conspicuous position in tent No. 1, near to the Chelsea Hospital entrance. It was the finest and most comprehensive exhibit of hydrangeas ever put up in London, and occupied some 400ft. The plants were shown in splendid form and condition and represented all the better sorts in cultivation and many superb novelties. As arranged on the western side of the tent, this somewhat unique bank of plants caught everybody's eye. The large and massive heads of blooms were shown in every tone of the paler blue colours, and these contrasted with the delicate pink and rose coloured sorts made a display that will long be remembered. Some of the better varieties were Etincelent, Marechal Foch, Krimhild, Parsifal, Mme. Truffant, Triumph, Lovely, Mme. Mouilliere and the huge sort Niedersachsen—altogether a superb display.

Messrs. James Carter and Co., set up a very large and beautiful almost square group comprising a great variety of greenhouse plants and hardy and half-hardy annuals grown under glass. The plants were in the pink of condition, being freely flowered and the colours pleasingly diverse: it was one of the brightest displays of its kind. The group was composed of a number of other smaller groups of regular and irregular formation and as a whole was a thing of beauty. Calceolarias were superb, as were cinerarias in Bouquet and Brilliant Prize forms. The streptocarpuses were beautiful, as were the schizanthuses, gloxinias and tuberous-rooted begonias. Lovely, too, were the examples of Primula obconica, petunias, Spanish irises and Antirrhinum Carter's Pink and A. Nelrose Improved.

Digitized by Google

Bowls of sweet peas on tall stands gave an effective finish.

A large group of flowering plants grown under glass was shown on the east side of tent No. 1 by Messrs. Webb and Sons (Stourbridge), Limited. The centre comprised a huge bank of cinerarias in diverse forms and colours, all flowering profusely. In the same exhibit there were also banks of superb schizanthuses and herbaceous calceolarias, both groups representing splendid types of these plants. There were also mounds of such plants as begonias, beautiful gloxinias and other flowering plants, all of which made a noteworthy exhibit. The front of the group was neatly finished off with ferns etc.

Mr. E. J. Henderson, gardener to Baron Schröder, set up one of the finest exhibits from a private garden in the whole Show. The group was arranged in semicircular form and comprised magnificent specimens of well grown, free-flowering schizanthuses in a great variety of colours and markings. This grower has a very fine strain of these plants. There were also beautiful examples of Calceolaria Clibranii and a large number of handsome plants of the herbaceous calceolaria. Beautiful palms as a background and pterises as an edging in the front, together with the capital arrangement of the group, left nothing to be desired.

The Chelsea Show would not be regarded as complete without an exhibit of tuberous-rooted begonias from Messrs. Blackmore and Langdon, who arranged one of their inimitable table-groups of these wonderful flowering plants. They have done so much to improve the begonia that the public have come to regard this firm as in duty bound to produce something new and choice each season, and the public were not disappointed this year, notwithstanding the difficulties of the present season. Superb examples of the respective varieties were seen in every instance, a few of the more noteworthy being Hilda Langdon (shell pink), Lucy V. Toner (deep rose), Lady Cory (superb orange salmon), Mrs. J. Davidson (deep yellow), Peace (cream, almost primrose), Mrs. Calthrop (lovely salmon-pink), Nurse Cavell (white), Lord Lambourne (orange-salmon), Mrs. T. Crawford (frilled pink), Royal George (glorious velvety crimson-scarlet) and Mrs. F. Bedford (blush). The basket begonias were also very pretty, three of the best being Eunice (pink), Mollie (blush) and Mrs. Bitkey (salmon-orange). It is a matter for regret that more space cannot be given to a description of this fine exhibit.

Dwarfed Japanese trees and miniature landscape gardens were shown by the Yokohama Nursery Company. A rare specimen of the tufted form of Thuya obtusa was noteworthy, reputedly 100 years old. There were numerous specimens of the ordinary form of Thuya obtusa and other specimens of Ginkgo biloba (maidenhair tree), Pinus pentaphylla, Juniperus procumbens and acers, oaks and azaleas in variety. This exhibit was shown in No. 2 tent.

At the Embankment end of tent No. 2 Messrs. W. Cutbush and Son, Limited, showed, among other things, a group of hydrangeas and ericas pleasingly disposed in undulating fashion among acers, palms, etc. Erica magnifica was well shown, as were Hydrangeas Marechal Foch, Lorely, Parsifal, Helge and General Viscomtesse de Vibraye.

About forty bunches of zonal pelargoniums were shown by Mr. R. J. Case, The best of the single-flowered sorts were Staplegrove Pride, Taurus, P. R. Johnson and Pride of the West. Double-flowered sorts were best seen in C. Heomans, Mme. A. Roseleur, Emperor Nicholas and Golden Glory.

A PORTION OF MESSRS. BLACKMORE AND LANGDON'S MAGNIFICENT BEGONIAS.

We were particularly charmed with the beautiful dwarf free-flowering plants of the newer type of schizanthuses shown by Mr. Alfred Dawkins. He had a table group of these floriferous plants that may be regarded as second to none in this great Show. Th ediverse colouring of the dainty flowers and their charming markings stamped them as of ideal quality. Fascinating aptly describes them, and they were much admired. The new calceolaria New Buttercup is really a most lovely yellow acquisition.

Choice ferns as exhibited by Messrs. Ellisons, made a superb table group. The plants were in the pink of condition and were set up in most attractive fashion. Especially noteworthy were Lastrea lepidum, Cheilanthes hirta Ellisiana, Gymnogramme Peruviana argyrophylla, Didymochlæna lunulata, Adiantum Hillii, A. Faulkneri, A. elegantisimum, Davallia fejeonsis robusta, D. Speluncæ, D. tenuifolia stricta and a plethora of most beautiful plants all worthy of mention.

Messrs. Jarman and Co., as usual, showed zonal pelargoniums in bunches, and they were highly attractive and pleasing. A few of the better single-flowered varieties were Maxim Kovolesky (a rich vermilion), Cassiope, Uranus, St. Louis, General Wolseley and Cymric. Semi-double and double-flowered sorts worthy of note were Paul Reboux, Lave, F. Poitvine and Ville de Poitvine, and were conspicuous.

A beautiful group in No. 1 tent was shown by Messrs. John Peed and Son, comprising both foliage and flowering stove and greenhouse plants. Caladiums in the centre of the group were good, and included most of the better sorts, charming streptocarpus, well marked gloxinias, hydrangeas, amaryllis, petunias, etc., all maintained the reputation of this well known firm.

Messrs. Godfrey and Son, staged a table group of show, regal and fancy pelargoniums in round baskets, in which small plants look quite well. The be

SOME OF THE STOVE AND GREENHOUSE PLANTS SHOWN BY MESSRS. J. PEED AND SON.

Digitized by Google

varieties appeared to be Fashion, Lieut. Warneford, Fire King, Fascination, Magnate, Topsy, The Prince, Negro, Devonshire Cream, The Queen and some good seedlings. There were also some schizanthuses.

Messrs. Stuart Low and Co., made an exhibit of miscellaneous plants in the form of a table group, included in which there were many useful and interesting plants. Plants worthy of mention were Boronia polygalifolia, Aotus gracillima, Boronia heterophylla, Bougainvillæa Mrs. Butt, Eutaxia myrtifolia and numerous other interesting things.

Messrs. L. R. Russell, Limited, worthily maintained their well deserved reputation with the large and massive group of stove and greenhouse plants in great variety, which they exhibited near to the Hospital entrance of No. 2 tent. The character of the display was most comprehensive, and included, among other things, excellent examples of the beautiful Codiæums, which are popularly known as Crotons. These included such varieties as Thompsonii, resplendens, B. Comte, Weismanii and Reidii. Other noteworthy plants were Dracænas Lord Wolseley, Prince Manouk Bey, Sanderiana and Victoria. Caladiums Mrs. L. R. Russell, Mrs. Laing, Rising Sun and candidum, seedling anthuriums, the fine anthurium Lord Lambourne, and the beautiful ruby-flowered Gloriosa Rothschildiana. There were numerous other choice plants which space will not permit us to mention.

A small table group of hydrangeas was shown by the Maytham Gardens. The plants were freely flowered, the only named variety being Mme. Mouilliere.

Caladiums as shown by Mr. Henry B. Brandt, Surrey (gardener, Mr. H. Cook), made an attractive group in No. 1 tent. The grouping in colours was distinctly effective with such sorts as John Peed, Mrs. L. R. Russell, Triomph de L'Exposition and Mikado. Other good plants were Pintato, Itapocii, Capabaribe, C. E. Dahle, Mrs. Laing, Duchess of Teck, Angustura and the dainty little Argyrites. With foliage plants as an edging and others interspersed the effect was quite good.

Schizanthuses as exhibited in a small group by Messrs. Watson and Simpson, Limited, were as near perfection as possible. There were only thirteen plants, but every one was good. The colours and markings were superb, the plants freely flowered, and their habit excellent. This firm has a splendid strain of these plants.

SUCCULENTS

Quaint forms of vegetation have an attraction to even the most "arty" of gardeners, and though comparatively few understand their points or have any real wish to collect them, few can pass by a collection of succulents without staying to admire the vegetable hedgehogs, and so forth.

The best collection of these xerophytic types was staged by Mr. Sydney Smith, and his plants included a very nice piece of Mamillaria micromeris and another of the woolly M. plumosa, a fine plant of Echinocactus recurvis, and a quantity of perfectly grown, though not necessarily large, specimens of Opuntia cylindrica and its quaintly dissimilar variety cristata, O. leucotricha and others of the prickly-pear clan, Cereus longisperma and others, Ariocarpus retusus, gasterias, cotyledons, and so forth.

Miss Worth also had an interesting and useful group, which included an Old Man cactus (Pilocereus) said to be fifty or more years old, Analonium fissauratum (attractive), cereus in several forms, echinocereus, echinocacti, cotyledons and mesembryanthemums. Some of the mesembryanthemums were from seeds which went down with the ill-fated "Kinfauns Castle," and, as the packages were saturated, it would appear that salt water is not detrimental to seed of mesembryanthemum.

Mr. H. A. Ellison showed some small cacti of various types as a foreground to a group of Japanese fern monstrosities (Davallia bullata).

It is a little strange that the hardy cacti—opuntias and so forth—do not appear more frequently in the hardy plant exhibits. They would at least attract attention to other (and perhaps better) things.

PALMS AND CYCADS

If memory serves us aright, this is the first time that this heading has been necessary for a report of the Chelsea Show; that is, unless we consider the Great International Exhibition of 1912 as the first "Chelsea."

A SMALL SECTION OF MESSRS. CHARLESWORTH'S COLLECTION OF ORCHIDS.

True, there was only one exhibit on this occasion, but that one was a particularly fine one, comprising more than thirty kinds. The exhibitors were Messrs. Robert Green, Limited, and the species shown in quantity were Kentias—Belmoreana, Forsteriana and Dumoniana—Cocos flexuosa and Phœnix canariensis; but there were notable specimens of other kinds. Four specimen Kentias dominated the whole, the best of these, we should say, being a perfectly balanced K. Forsteriana quite 20ft. high. Of smaller specimens, the bamboo-like Cocos flexuosa was worth noting, so were the finely cut but very hardy Phœnix Rœbelini—one particularly good specimen on show—the graceful Cocos Weddelliana, two hardy species of trachycarpus and some greenhouse forms of the nearly allied genus chamærops, the quaint Cocos Yatay, a quaintly stodgy and yet uncharacterised plant of Ceroxylon niveum (a species which, apparently, does not hurry to "put its hair up"), Arenga saccharifera and Caryota sobolifera with curious trapeziform foliage. Of the cycads, a particularly fine piece of Cocos flexuosa was on view. In these days of Belgian palms it is pleasing to know that these were British grown from seed and to see how very favourably they compared with their Continental rivals.

ORCHIDS

The fact that the Sherwood Cup for the most meritorious group in the Show was awarded to orchids proves that these beautiful plants have fully maintained their reputation as the aristocrats of the floral world.

Messrs. J. and A. McBean were awarded the Sherwood Cup for a most praiseworthy exhibit of various species and hybrids. The group occupied one end of the orchid tent, and contained many remarkable odontoglossums, such as O. crispum var. Pearl McBean, with large white flowers, and O. c. var. Priscilla. Blotched odontoglossums were equally fine, as also were the many richly coloured odontiodas. Mention may be made of Odontioda Queen Mary, of bright red colour, of O. Radiant var. majestica, which received a F.C.C. at Chelsea last year, and of O. Dovere, which on this occasion received an award of merit. The centre of the group was composed of cymbidiums and white odontoglossums, while neatly arranged in the bays were fine varieties of Cattleya Mossiæ and many superb lælio-cattleyas. Miltonias of the vexillaria section were in excellent condition and included many of the blotched forms

Messrs. Charlesworth and Co. had an equally large exhibit, containing in the centre a mass of Odontoglossum Wilckeanum aureum with golden yellow flowers effectively arranged with the soft mauve blooms of Lælio-Cattleya Fascinator. At each end were selections of newer hybrids, including many odontonias, in which the large labellums stood out prominently. Brasso-Cattleyas were a feature, and included the large B.-C. Pallas, as well as B.-C. Apollo. Cymbidiums and oncidiums were effectively staged, and pretty effects were produced by carefully staging tall plants of Vanda teres. Among the cymbidiums that known as Landrail var. citrinum bore flowers of an unusual citron-yellow colour, while along the front rows were several distinct forms of Miltonia vexillaria and its hybrids. White cattleyas were represented by C. Mrs. Myra Peeters, and the coloured ones by C. Tityus.

Sir Jeremiah Colman, Bt., had a magnificent collection of rare species and pretty hybrids. The former comprised the curious Eria ornata, the rose-tinted Sarcopodium Lyonii, a varied selection of quaint masdevallias and Cattleya intermedia var. Aquinii, in which the petals are flushed with purple, as normally seen on the labellum. Brightness was given to the group by including many yellow-flowering odontoglossums and choice odontiodas of scarlet tints. Among the albinos were well developed flowers of Cattleya Skinneri alba, white hybrids of the genus, and superb examples of the Brasso-Cattleya Gatton Lily. The pretty blue-flowering Dendrobium Victoria Reginæ, as well as new hybrids of the D. nobile section, were placed in prominent positions, and along the back row were selected cymbidiums and various oncidiums.

Messrs. Sanders showed an extensive exhibit of excellent cymbidiums, the tall and richly coloured spikes making a most attractive feature of the Show. Deserving of mention were Cymbidium Ceres var. Empire and C. brugense var. Rosy Queen. Among the numerous hybrids were handsome odontoglossums of the blotched section, such as Magpie and Everest, while among the pretty lælio-cattleyas that distinguished as Isabel Sander var. Glory stood out prominently, and L.-C. Erica Sander may also be mentioned on account of its pleasing qualities.

Messrs. Cowan and Co. had a fine exhibit, the cattleyas and odontoglossums being outstanding features. The former included C. Tityus, unusually well developed, and the latter the handsome

Digitized by Google

O. Amazon (crispum × mirum). At each end were batches of cypripediums, the albino forms well represented. Miltonias and lælio-cattleyas added to the attractiveness of this exhibit.

Mr. H. T. Pitt staged the best exhibit by an amateur. Meritorious plants were Odontioda Duchess of York with a spike of twenty-one orange-red flowers, the handsome Miltonia William Pitt, Sarcopodium Lyonii with three many-flowered spikes, a large plant of the quaint Nanodes Medusæ and also of Angulos Clowesii.

Messrs. Stuart Low and Co. showed a large group, choice cattleyas being well represented by C. Mendelii var. Stuart Low with three large pure white flowers. An interesting plant was Cattleya Suavior var. Gracy, the tips of the petals heavily flushed with purple, as usually seen on the lip. Lælio-cattleyas were seen in Aphrodite and Fascinator, while odontoglossums were well staged in Princess Yolande, rich purple, and in Felix, which secured an award of merit. A charming hybrid was Odontioda Evangeline, the segments margined with rose, the petals prettily spotted. Dendrobium dixanthum with bright yellow flowers and Vanda Parishii came in for appreciation.

Messrs. Cypher and Sons had an effective group containing many rare species, such as masdevallias and epidendrums. Cypripediums were at their best in Maudiæ and Rothschildianum, while lælio-cattleyas were represented by Canhamiana, Aphrodite and Fascinator. White cattleyas comprised Dusseldorfei Undine, and other members of the genus were seen in Adula and Mossiæ. Miltonia vexillaria is always a popular plant, and many pleasing varieties and hybrids of it were here included.

Mr. J. J. Joicey staged a meritorious exhibit containing the fine Epidendrum prismatocarpum, nice examples of Angulos Clowesii, popularly known as the cradle-orchid, and various cypripediums. A feature of this group was two specimen plants of the old Selenipedium Dominianum, with long-tailed petals, while another orchid that attracted equal attention was Odontoglossum crispum var. Joiceyi with a spike of six large, white flowers, the margin of the segments prettily toothed. Brasso-cattleyas were staged in Caligula and St. André, while Miltonias of the vexillaria section included many of the blotched section.

Mr. Harry Dixon had an attractive exhibit embracing many popular orchids. Fine varieties of Cattleya Mossiæ, the interesting Maxillaria tenuifolia and various miltonias were all well staged. Among the lælio-cattleyas was one called Sunbeam, with flowers of golden apricot colour. Lælia tenebrosa and several richly coloured varieties of Odontioda Charlesworthii came in for well merited praise.

Mr. J. J. Bolton staged a selection of handsome odontoglossums, including O. crispum var. Renown, O. eximium var. Leonara with reddish blotching, and O. eximillus, very pretty. Among the odontiodas that known as Coronation stood out prominently.

Messrs. Mansell and Hatcher had a fine exhibit comprising many pleasing varieties of Lælio-Cattleya Fascinator. One had no fewer than seven flowers on the spike, and there were several with five. Miltonia Venus and M. Bleuana were in excellent condition, as also were some brasso-cattleyas and various cypripediums. Odontoglossums were staged well in Lenore and a promising novelty called J. Hacking.

Mr. R. Gerrish exhibited Odontoglossum Belenus (amabile × Olympia) and Odontioda Laura (Brewii × Coronation), both meritorious plants and well cultivated.

NEW & RARE PLANTS

ARISÆMA CANDIDISSIMA.—A dwarf arum-like plant which responds to the same treatment. The spathe was of unusually good shape for the genus. It is pea green coloured from the base half-way up, when it is milky white. The veins are prominent throughout. The large palmate dark green leaf is set almost at right angles to the stalk. Award of merit. Shown by Mr. A. K. Bulley.

CARNATION CAROLA STRIATA.—The name fairly describes this novelty, for it has the form of the well known Carola with reddish-purple lines on the petals. Award of merit. Shown by Mr. C. Engelmann.

C. SIR PHILIP SASSOON.—This magnificent dark crimson perpetual-flowering variety has often been admired at Vincent Square during the winter and spring. Award of merit. Shown by Messrs. Stuart Low and Co.

DIANTHUS MUSULÆ.—A very dwarf, compact, almost congested little pink which in bloom becomes a mass of small rosy mauve flowers. Award of merit. Shown by Mr. A. K. Bulley.

GERANIUM FARRER'S PINK.—A compact little plant not more than 4ins. high and bearing plenty of flowers quite an inch across and of delicate silvery pink colouring. Award of merit. Shown by Mr. C. T. Musgrave.

IRIS CARMELO.—A lovely tall species of delightful soft blue colouring. The long drooping falls are delicately lined. Award of merit. Shown by Mr. W. R. Dykes.

LINUM NARBONNENSE TILGATE BLUE.—The habit is somewhat tall and weedy even for a linum, but one forgives this for the beautiful flowers of Browallia speciosa size and colouring. Award of merit. Shown by Mr. H. Hemsley.

MECONOPSIS PRIMULINA.—A very uncommon "Himalayan Poppy." It is a plant of rather delicate appearance. The leaves are narrow, smooth and dark, making a neat rosette from which spring a clean-stemmed nodding, rounded flower of bluish mauve colouring. Award of merit. Shown by Mr. A. K. Bulley.

MECONOPSIS PSEUDO-INTEGRIFOLIA.—A much sturdier species. The pale green leaves and stems are hairy and more erect, and the branched inflorescence carried several large widely expanded primrose yellow flowers of delicate beauty. First-class certificate. Shown by Mr. A. K. Bulley.

PIERIS FORRESTII.—Several species of pieris (generally known in gardens as andromeda) have beautifully coloured young leaves, but none is so delicately tinted as this, nor so lovely. The flowers were almost over, but they are large for the species and appear to have been white. But if only for the gorgeous young foliage it is well worth growing. Award of merit. Shown by Mr. A. K. Bulley.

PINK FIRE KING.—A compact and fully double flower almost of carnation size and rich scarlet colour. Award of merit. Shown by Mr. C. H. Herbert.

PINK MRS. GIFFARD WOOLLEY.—Another splendid new pink. The perfectly formed flowers are even larger than those of the foregoing. The colour is soft pink and the flowers are deliciously fragrant. Award of merit. Shown by Mr. C. H. Herbert.

RHODODENDRON GRIERSONIANUM.—A very vividly coloured species which seems to flower at an early age. The loose truss is made up of goodly sized orange-scarlet flowers which have tiny maroon spots. The young stems and undersides of the leaves are tomentose. First-class certificate. Shown by Mr. T. H. Lowinsky and Mr. Lionel de Rothschild.

SYRINGA MARECHAL LANNES.—This is a single-flowered garden lilac which has a very large truss made up of plenty of large "pips" of pale lilac colouring and reddish exteriors. Quite a giant among the lilacs. Award of merit. Shown by Mr. R. C. Notcutt.

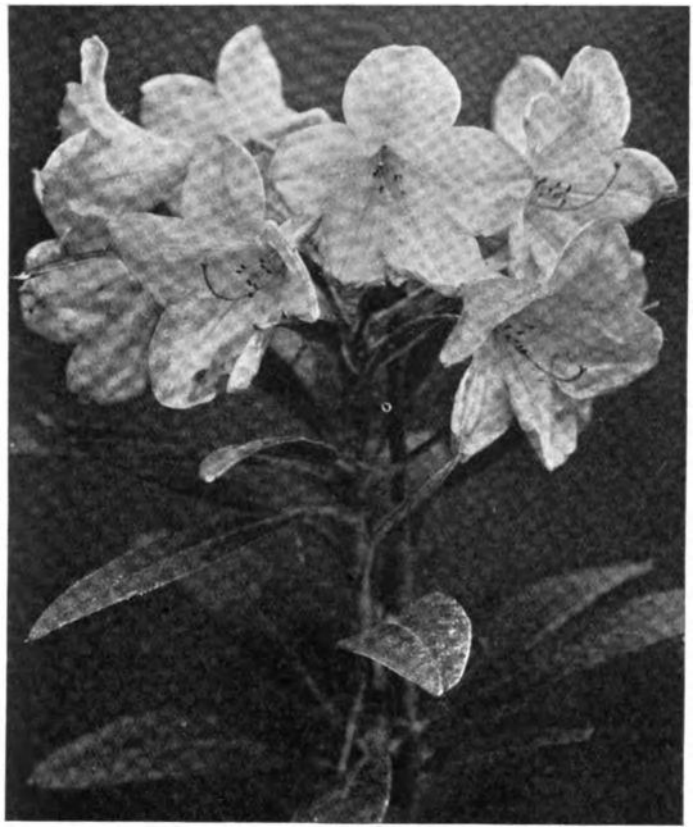
SYRINGA PASTEUR.—Another giant single lilac. In this case the colour is a deep vinous red and the large pips are incurving. Award of merit. Shown by Mr. R. C. Notcutt.

TULIP AMBER.—A beautiful May-flowering tulip of large size, good form and rosy amber colouring. Award of merit. Shown by the Welsh Bulb Fields Company.

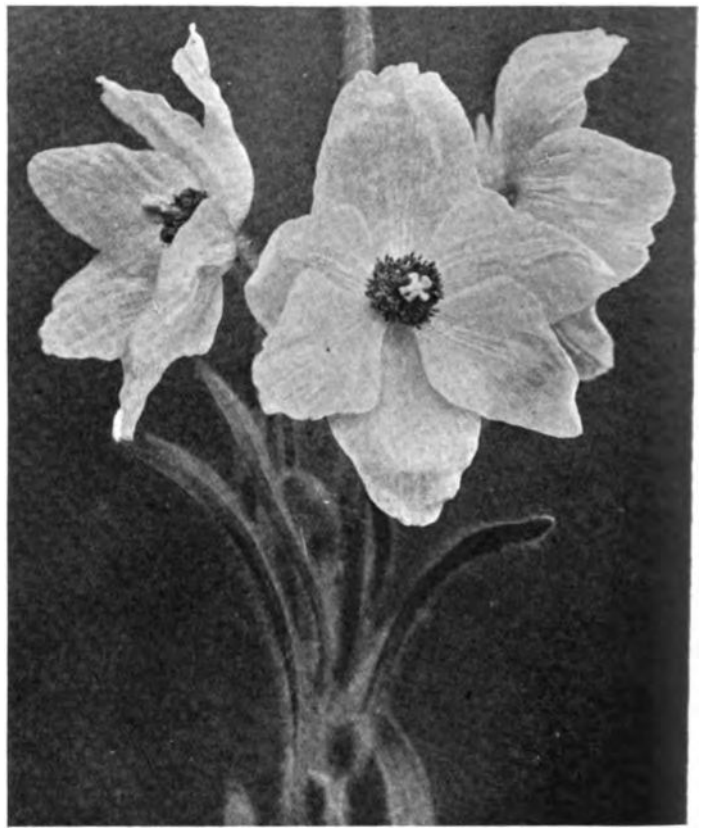
TULIP PRINCE OF ORANGE.—Another good May-flowering tulip. The interiors of the flowers are rich orange-coloured, while the outsides are heavily flushed with red. Award of merit. Shown by the Welsh Bulb Fields Company.

GERANIUM FARRER'S PINK.

Digitized by Google



A FINE RHODODENDRON SPECIES; R. GRIERSONIANUM WITH BRILLIANT ORANGE-SCARLET FLOWERS.



MECONOPSIS PSEUDO-INTEGRIFOLIA, PRIMROSE YELLOW; OF GREAT DELICACY AND GRACE.

ORCHIDS

FIRST CLASS CERTIFICATES.

ODONTOGLOSSUM MONARCH (Aglaon × majesticum), from Messrs. Cowan and Co. A handsome hybrid bearing a spike of six large flowers, white, tinged with rose in the central area of each segment, and effectively spotted with red, the lip broadly developed.

ODONTOGLOSSUM CRISPUM VAR. EVANSLÆ, from Mr. John Evans. One of the finest forms of this popular species, the arching spike carried nine flowers, much above the normal size, of creamy white texture, the only colour being an occasional reddish spot on the labellum.

AWARDS OF MERIT.

CATTLEYA TITYUS VAR. QUEEN MARIE (Octave Doin × Enid superba), from Messrs. Cowan and Co. A grand hybrid; the spike bore two large flowers in which the segments were well developed, especially the broad petals, in colour blush rose, the expansive labellum deep purple and with an orange-yellow throat.

CYMBIDIUM CERES VAR. EMPIRE (I'Ansonii × insigne), from Messrs. Sanders, St. Albans. The tall, erect spike carried eight finely developed flowers of crimson-pink colour tinged with red.

ODONTIODA IDUNA (Odontioda Chanticleer × Odontoglossum illustrissimum), from Mr. Gerrish, (gardener, W. Sorrell). This hybrid carried a spike of six flowers of moderate size and of deep reddish scarlet colour.

LÆLIO-CATTLEYA DOMOS MAJESTICA (C. Mossiæ × L.-C. Dominiana), from Messrs. Cowan and Co. One of the best forms of this hybrid, the large flower of rosy mauve colour, the broadly developed labellum mottled with darker tint.

ODONTOGLOSSUM CRISPUM VAR. HARVEST MOON, from Mr. H. T. Pitt. A very beautiful form of this Colombian species. The bending spike bore six large flowers, in which the outstanding feature was the breadth of the snow white segments.

ODONTOGLOSSUM FELIX, from Messrs. Stuart Low and Co. This well grown plant, of unrecorded parentage, carried a tall spike of ten large flowers, cream tinted, the sepals marked with a bold reddish purple blotch, the petals prettily spotted.

ODONTIODA DOVERE (Odontioda Diana × Odontoglossum illustrissimum), from Messrs. J. and A. McBean. A charming hybrid, in which the arching spike carried thirteen flowers, the segments having a broad margin of deep mauve colour, the central area blotched with reddish scarlet.

ARISÆMA CANDIDISSIMA.

ONCIDIUM PAPILIO VAR. ATLAS, from Messrs. Charlesworth and Co. Probably the finest form yet seen of this attractive species, the butterfly-like bloom of which attracted much attention.

HORTICULTURAL SUNDRIES

Sundries were as numerous as ever this year, and, as usual, the exhibits were situated down the Lime Avenue and in close proximity to it.

A large collection of watering cans of all shapes and sizes was displayed by Mr. Haws of Clapton.

Messrs. McDougall and Robertson, Limited, of Manchester, showed their well known insecticide Katakilla and a large assortment of insecticides, fertilisers and weed killers.

The famous Acme labels were shown by Mr. John Pinches of Camberwell. Here, too, were to be seen his "Radiate" stands. These are very popular with exhibitors as they are suitable for almost any flower. His "Corona" flower displayer attracted the attention of the ladies; it is ideal for rose bowls. Exhibition boxes (as used by the National Rose Society), vases of all descriptions in zinc and tin, pergola chains, together with a large assortment of other good things, were also shown.

Cascade nozzles for water cans were shown by Messrs. Webster and Sons of Stock.

Fibrous yellow loam was exhibited by Mr. A. B. Johnson of Cranleigh.

Various fumigants, fertilisers, weed killers and mildew washes were displayed by Messrs. H. Scott and Sons of Woodside.

Fertilisers were shown by the Radium Fertiliser Co. of Woodford Green.

A varied selection of garden tools, syringes and garden furniture was displayed by Messrs. T. Gunn, Limited, of Fore Street, E.C.2.

Messrs. Wm. Cooper and Nephews, Limited, of Berkhamsted, exhibited their well known spray fluids, weed killers and fungicides.

Folding garden furniture was shown by Messrs. Abbott Bros. of Southall.

Horticultural washes, insecticides and guanos were displayed by Messrs. Voss and Co. of Millwall.

The well known Atco Motor Mower was shown by Messrs. C. H. Pugh, Limited, of Birmingham. Last year we had under trial one of these machines and it proved very satisfactory.

A large assortment of garden ornaments was displayed by Messrs. Pulham and Son of Oxford Street. Here were to be seen sundials, stone garden seats, well-heads and bird baths.

The J. P. Super Lawn Mowers, Limited, exhibited their well known lawn mowers.

A large assortment of patent extension ladders and platform steps was displayed by Messrs. Drew, Clark and Co., of Leyton.

Messrs. Ransomes of Ipswich exhibited their well known mowing machines, including the "motor" variety.

Garden pottery was displayed by the Potters' Art Guild of Guildford.

Horticultural washes and sprays were shown by the famous Jeyes' Sanitary Compounds Company, Limited, of Cannon Street.

Spraying machines and syringes were exhibited by the Eclipse Spraying Company of Birmingham.

Messrs. Prentice Brothers, Limited, of Stowmarket showed their well known tomato fertiliser Tomorite and other fertilisers.

Messrs. E. H. Taylor of Welwyn displayed their well known beehives and appliances.

Beehives were also exhibited by Messrs. C. T. Overton and Sons of Crawley.

Garden tools comprised the exhibit of Messrs. Holtzapffel and Co. of the Haymarket.

"Neuespraya" for watering cans were shown by Mr. J. Singleton of Fulwood. It is claimed that these do not become clogged like the ordinary rose.

The Stewart "Rain King" lawn sprinkler was shown and demonstrated by the Cooper Stewart Engineering Company, Limited, of Bloomsbury. This sprinkler is ideal for lawns, especially tennis lawns and bowling greens.

Overhead watering machines and rotary sprinklers were shown by the British Overhead Irrigation, Limited, of Shepperton.

Messrs. H. Pattison and Co. of Streatham displayed their famous horse boots. They also showed water sprinklers and Sarel's patent spiked roller. The latter is exceptionally useful for golf courses. It drains and aerates the turf and it does not tear the grass. This firm also showed rollers suitable for hard tennis courts.

Mowing machines, both of the motor and "push" varieties, were displayed by Messrs. A. Shanks and Sons of Cannon Street.

Propagating frames and wall frames were exhibited by the Woodworkers, Limited, of Letchworth.

Fibrex pots were displayed by Mr. J. N. Harvey of Evesham.

An exhibit which drew considerable attention from the ladies was that of Dryad cane furniture shown by the Dryad Cane and Metal Works of Leicester.

A varied assortment of garden tents was shown by Mr. H. E. Pocock of Salisbury.

A very large collection of spraying machines and syringes of all descriptions and for all purposes was shown by the Four Oaks Spraying Machine Company of Sutton Coldfield.

Garden furniture was displayed by Messrs. T. Syer and Co. of Wilson Street, E.C.

Messrs. Carter and Co. of Raynes Park had an extensive exhibit of horticultural sundries. Here were to be seen garden tools, sprayers, hose, mowing machines, garden pottery and garden furniture.

Greenhouses and heating apparatus were shown by Messrs. Hayward and Co. of Brockley.

Mr. H. C. Slingsby showed ladders, wheelbarrows and trucks.

Spraying machines, fertilisers and insecticides of all descriptions were exhibited by the Stonehouse Works Company of West Bromwich.

The Willmott plant stakes were shown by Mr. H. J. Greenwood of Bracknell.

Motor lawn mowers were displayed by Messrs. Dennis, Limited, of Guildford.

A large collection of sundials, nesting boxes and bird baths were exhibited by Messrs. A. H. Moorton, Limited, of Buckingham Palace Road, S.W.

Both ordinary and motor mowing machines were displayed by the Godiva Engineering Company, Limited, of Slough.

Messrs. Geo. Monro, Limited, of Covent Garden exhibited spraying machines, garden tools and pottery. This firm is *wholesale* only.

Carnation food, supports, labels and insecticides were shown by Messrs. Allwood Brothers of Hayward's Heath.

Garden furniture was displayed by the Papworth Industries of Cambridge.

Garden tools, hose, nozzles, spraying machines and syringes were exhibited by Messrs. R. Melhuish, Limited, of Fetter Lane.

"Metro" chemical products were displayed by the South Metropolitan Gas Company of the Old Kent Road, S.E. Sulphate of ammonia was conspicuous on this stand.

The well known Red Spider Death, Niquas non-poisonous insecticide, lime sulphur wash and fungicide, and lawn sands were shown by Messrs. Corry and Co., Limited, of Covent Garden.

The Key Fertiliser Company of Chelsea exhibited a small lawn which had originally been meadow land. This had been treated with their Key Fertiliser for a little time and, judging by the results obtained, this fertiliser should soon become very popular.

Insecticides and fumigants, including their well known Gyp and nicotine spraying fluids, were shown by Messrs. Ed. Cook and Co., Limited, of Bow.

Garden rustic work, tools and stone were shown by Mr. W. Unwins of Woodside.

The Wilkinson Sword Company of Pall Mall exhibited their well known pruners, including some new models.

Bird baths, sundials and other garden ornaments were displayed by Messrs. Kelly and Co. of Marylebone Road.

The famous Abol syringes and Abol insecticides and fungicides were displayed by Messrs. Abol, Limited, of Paddock Wood.

Their patent continuous cloche was shown by the Chase Continuous Cloche Company of Chertsey.

Spraying machines, portable pumps and syringes were shown by Messrs. Martineau and Smith of Birmingham.

Messrs. Robinson Brothers, Limited of West Bromwich (Staffs) exhibited their well known Multiple plant food. This firm also showed lawn sands and various fertilisers.

Messrs. Hughs, Bolckow and Co., Limited, exhibited garden furniture.

A very extensive exhibit of heating apparatus was by Messrs. Chas. Kinnell and Co., Limited, of Southwark Street. This included their well known boilers the Horse Shoe, the Bison and the Rochford. They also showed their new twin boiler.

A large collection of garden tents, hammocks and garden furniture was shown by Messrs. Piggott Brothers of London E.C.2.

Messrs. Duncan Tucker and Sons, Limited, of Tottenham showed a large collection of garden frames for all purposes. Also small greenhouses and an admirable conservatory.

Wire tension greenhouses were exhibited by Messrs. Skinner, Board and Co of Bristol.

An extensive exhibit of garden ornaments, including vases, sundials and bird baths was exhibited by Messrs. Sander and Co. of Regent's Park.

Garden furniture, mowing machines and rollers were displayed by Messrs. Gamages.

Messrs. Messenger and Co. of Loughborough displayed their well known Loughborough boiler. They also showed greenhouses and garden frames.

Mowing machines of all descriptions, garden tools, spraying machines, syringes, greenhouses, frames, garden furniture, bird baths and garden urns were exhibited by Messrs. Wm. Wood of Taplow. They also showed their well known plant food Le Fruitier.

Garden furniture and summer-houses were shown by Messrs. Harrods.

Messrs. Boulton and Paul of Norwich showed garden frames, including span-roof sorts, ironwork archways suitable for roses, water barrels with pumps, and many photographs depicting the work that they have carried out in the construction of greenhouses in all parts of the country.

Messrs. Gaze showed garden figures, urns, bird baths, stone seats and a miniature hard tennis court.

OFFICIAL LIST OF AWARDS

CHALLENGE CUPS.

Sherwood Cup, for the most meritorious exhibit in the Show: Messrs. J. and A. McBean for a group of orchids.

"*Daily Graphic*" *Cup*, for the best rock garden: Messrs. T. R. Hayes and Sons.

Orchid Challenge Cup, for the best exhibit of orchids by an amateur on a space not exceeding 60 sq. ft. Only those may compete who employ not more than three assistants in orchid houses (including the head gardener): Mr. H. T. Pitt.

SPECIAL CUPS.

Allwood Carnation Bowl, for the best group of carnations exhibited by an amateur: Mr. F. W. Seymour.

Sutton Silver Cup, for the best amateur exhibit of vegetables: The Hon. Vicary Gibbs (gardener, Edwin Beckett).

Orchids.—Gold medal: Charlesworth and Co., J. and A. McBean, and Sir Jeremiah Colman, Bt. (gardener, J. Collier). Silver cup: Sander's. Silver-gilt flora medal: Cowan and Co., J. Cypher and Son, H. T. Pitt, and Stuart Low and Co. Silver-gilt Banksian medal: J. J. Joicey (gardener, J. Mackay), and Mansell and Hatcher. Silver Flora medal: H. Dixon. Silver Banksian medal: J. J. Bolton.

Fruit and Vegetables.—Gold medal: Hon. Vicary Gibbs (gardener, Edwin Beckett), for vegetables. Silver cup: G. Bunyard and Co., for fruit; and T. Rivers and Sons, for fruit trees in pots. Silver Hogg medal: Laxton Bros., for Strawberries; and V. C. Vickers, for raspberries. Silver Knightian medal: Dobbie and Co., Limited, for potatoes. Vote of thanks: Mrs. Radcliff, for strawberries.

Delphiniums, Tulips, etc.—Silver-gilt Flora medal: Blackmore and Langdon, for Delphiniums; G. R. Downer, for lupins; and Dobbie and Co., for tulips. Silver-gilt Banksian medal: V. C. Vickers, for aquilegias. Silver Flora medal: E. Paul and Co., and W. A. Watts, for tulips; W. Yandell, for Violas; and Reamsbottom and Co., for anemones. Silver Banksian medal: H. Clarke, for violas.

Digitized by Google

Sweet Peas.—Gold medal: R. Bolton and Son and Dobbie and Co., Limited. Silver-gilt Flora medal: A. Dickson and Sons, Limited. Silver-gilt Banksian medal: Andrew Ireland and Hitchcock. Silver Flora medal: J. Stevenson, and Sutton and Sons.

Dahlias.—Silver Banksian medal: Carter Page and Co.

Rock and Formal Gardens.—Gold medal: T. R. Hayes and Sons, and G. G. Whitelegg, for rock gardens. Silver cup: James MacDonald, for grass garden. Silver gilt Flora medal: Backhouse Nurseries, Limited, Clarence Elliott, Limited, and Pulham and Sons, for rock gardens; W. H. Gaze and Sons, J. Cheal and Sons, and R. Neal and Sons, for formal gardens. Silver-gilt Banksian medal: Hodsons, Limited, for rock garden; Kent and Brydon, Limited, and Italia House, for formal garden. Silver Flora medal: W. Cutbush and Son, Limited, for rock garden; J. Carter and Co., and H. Brook, for formal gardens.

Primulas.—Silver Flora medal.—Dr. MacWatt.

Shrubs.—Gold medal: Lady Aberconway, for rhododendrons; R. C. Notcutt and R. and G. Cuthbert, for shrubs; G. Jackman and Son, for clematis; Waterer, Sons and Crisp, for shrubs and rhododendrons. Silver cups: J. Cheal and Son, for shrubs. Silver-gilt Flora medal: A. Charlton and Sons, Fromow and Sons, R. Reuthe, and E. Hillier and Sons, for shrubs; M. Koster and Sons, for rhododendrons; L. R. Russell, Limited, for ornamental trees and shrubs; R. Wallace and Co., for rhododendrons, azaleas, etc. Silver-gilt Banksian medal: Donard Nursery Co., for shrubs; Yokohama Nursery Co., for Japanese trees; J. Klinkert, for topiary. Silver Flora medal: W. Cutbush and Sons, and Fletcher Bros., for shrubs; T. Lewis, for rhododendrons, etc. Silver Banksian medal: R. Gill and Son, Orpington Nurseries, Sir Arthur Vivian (gardener, A. A. Cavanagh), W. Watson and Sons, and G. G. Whitelegg, for shrubs; R. Green, Limited, for bay trees.

Mixed Groups.—Gold medal and congratulations: R. Wallace and Co. Silver cup: G. Bunyard and Co., W. H. Rogers and Son, Limited, and F. G. Wood. Silver-gilt Flora medal: Bees Limited, J. Cheal and Sons, and Amos Perry. Silver-gilt Banksian medal: J. C. Allgrove, Baker's Limited, Barr and Sons, G. Jackman and Sons, M. Prichard and Sons, Orpington Nurseries, and Storrie and Storrie. Silver Flora medal: R. H. Bath, Limited, Oliver and Hunter, and Waterer, Sons and Crisp. Silver Banksian medal: Godfrey and Son, Hewitt and Co., Maytham Gardens, Carter Page and Co., R. Reuthe, T. Carlile, Harkness and Sons, E. Scaplehorn, C. Turner, and W. Wells, Junr.

Various Groups.—Gold medal: Blackmore and Langdon, for begonias. Silver cup: Sidney Smith, for cacti. Silver-gilt Banksian medal: G. G. Whitelegg, for irises. Silver Flora medal: R. J. Bastin and Sons, for begonias; and Miss Worth, for succulents. Silver Banksian medal: H. N. Ellison, for cacti.

Roses.—Gold medal: J. and C. Allen. Silver cup: Elisha Hicks. Silver-gilt Flora medal: B. R. Cant and Sons, and W. E. Chaplin. Silver-gilt Banksian medal: F. Cant and Co. Silver Flora medal: W. Cutbush and Sons, and E. Paul and Co. Silver Banksian medal: George Prince.

Alpines.—Gold medal: R. Tucker and Sons. Silver cup: Clarence Elliott, Limited, and M. Prichard and Sons. Silver-gilt Flora medal: Bowell and Skarratt. Silver-gilt Banksian medal: Waterer, Sons and Crisp, Maxwell and Beale, Prichard and Co., and Skelton and Kirby. Silver Flora medal: G. Jones and Ingwersen, and G. G. Whitelegg. Silver Banksian medal: H. Hemsley, and Laird and Dickson. Bronze Flora medal: K. and E. Hopkins, and Sheppard's Sawhurst Nursery.

Carnations.—Gold medal: Allwood Bros., and C. Engelmann. Silver-gilt Flora medal: James Douglas and Stuart Low and Co. Silver Flora medal: Lieutenant-Colonel the Hon. George Herbert, Keith Luxford and Co., F. W. Seymour, and C. H. Herbert.

Hydrangeas, Stove and Greenhouse Plants.—Gold medal: H. J. Jones, for hydrangeas; L. R. Russell, Limited, for stove and greenhouse plants; Sutton and Sons, for flowering plants. Silver cup: J. Carter and Co., for flowering plants. Silver-gilt Flora medal: H. B. Brandt, for caladiums; J. Peed and Son, for stove and greenhouse plants; R. Green, Limited, for palms. Silver gilt Banksian medal: Alfred Dawkins, and Watkins and Simpson, Limited, for schizanthus; Baron B. Schroder, for schizanthus and calceolarias. Silver Flora medal: Stuart Low and Co and E. Webb and Sons, for greenhouse plants; Wm. Cutbush and Son, for hydrangeas. Silver Banksian medal: Godfrey and Son, for pelargoniums and lupins; Maytham Gardens, for hydrangeas. Vote of thanks: R. J. Case, for pelargoniums.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Treatment of St. Brigid Anemones (W. J. O.).—The planting season extends from September to April; it is best to plant only when the weather and soil conditions are favourable. The corms should be lifted and carefully dried and stored. It would be necessary to prepare the soil on the boundary of the wild garden, clearing away the grass from, at least, small spaces. These anemones will survive and grow satisfactorily in heavy ground if the latter is well drained. A light, rich soil in which there is plenty of leaf-soil, watering in dry weather and providing shade from bright sunshine are ideal conditions for these plants.

TREES AND SHRUBS.

The Japanese Cydonia (Cherry).—As the trees of Pyrus japonica have been badly neglected, it will be preferable to spread the hard pruning necessary over at least two years. It is late to do much this year, the end of March or early April being the best time for hard pruning. As, however, the growths are very thick, it will help matters to cut out a few of the oldest shoots at once. Next March cut half the long shoots right back, removing the oldest. Bend the remainder and tie in to the wall. By the next spring there should be sufficient young wood for you to be able to cut out most, if not all, the remaining old wood. In succeeding years do a little pruning each season after flowering to maintain a supply of healthy young growths.

Spruce Trees Attacked (J. G. W.).—Our correspondent's description of the trees suggests that they are badly attacked by the spruce aphis (Aphis abietina). There is some truth in the local information, as it is usual for the trees to be badly attacked one year and it then takes a couple of years to furnish the trees with new leaves. The best remedy is spraying with a paraffin-soap emulsion. Just now it must not be used as strong as in winter because of the new growths. When no spraying is done ladybirds have been known effectively to clear the trees of the green fly or aphis.

ROCK GARDEN.

Gentiana decumbens (C. J. G. D.).—The true Gentiana decumbens is a good plant with rosettes of strap-shaped leaves and decumbent branches, with long sprays of blue to white flowers. Probably the late Reginald Farrer did not see the true plant but only G. cruciata, which sometimes does duty for it in gardens.

FRUITS UNDER GLASS.

Mealy Bug on Grape Vines (W. J., Glamorgan).—Our correspondent could not have done better than he did in using Gishurst Compound during the winter months. The bugs conceal themselves in crevices and cracks and, unless the insecticide reaches them in such places, some are left to increase the stock the following spring. It generally takes several winters' work to completely eradicate mealy bug in bad cases. The pests move about freely on sunny mornings, and all found on the old wood should be touched with a tiny camel-hair brush dipped in paraffin. Next winter the pure Gishurst should be used to fill up all cracks on the hard wood, as it would mean certain death to all insects inside.

FRUIT GARDEN.

Pears Unsatisfactory ("Newlands").—The young leaves are not mildewed, but have the appearance of being damaged slightly by frosts and storms. Also, the caterpillars of the moth have done harm to the flowers. If there is a really good set of fruits, judicious thinning-out will do good; but it is too soon to commence this work, as many fruits, naturally, at a later stage of development, turn yellow and fall off.

MISCELLANEOUS.

Names of Plants.—M. W.—Lopezia coronata.——D. C.—Sedum Kirilowii.——H. C.—1, Spiræa arguta; 2, Azara microphylla; 3, Juniperus Sabina var.; 4, Skimmia japonica; 5, Choisya ternata.

TRADE NOTE

"THE GAZEWAY," SURBITON.

THE QUEEN OF RUMANIA, accompanied by her sister, The Infanta Beatrice of Spain, spent nearly an hour the other day in the show house and gardens known as "The Gazeway," Surbiton. Her Majesty expressed great pleasure with all she saw, but possibly the gardens pleased her most. They are looking particularly delightful at present with the varying shows of tulips and rock plants, and Her Majesty was so interested in some of the varieties that she is placing an order for a consignment to be sent out to her in Rumania. The Children's Garden also called for particular attention, and the very fine "All-Weather" hard tennis court (for which the firm of Gaze have become so famous and with which Her Majesty was already familiar) provoked much interest. The house itself, with its choice selection of antique and modern furniture set out in rooms decorated particularly to show the value of colour used in the home, next called for attention. Her Majesty very much admired the collection of lustre-glass and made full enquiries with a view to purchasing a selection. Photographs of the party were taken before Her Majesty left the grounds, and when leaving the Queen expressed to Mr. Sidney Gaze her great pleaure in the visit, and also her hope that she would be able to come to "The Gazeway" again before leaving England.

CORRESPONDENCE

DAFFODILS SENTINEL AND MITYLENE.

SIR,—The Brodie of Brodie has written to me to say that he was not the raiser of these two very beautiful Leedsii varieties (page 335, May 17th), but that he only possessed the main stock of them. They were raised by the Rev. G. H. Engleheart. Sorry for the error. The Brodie also tells me that he has some Queen of the West daffodil. I wonder how it does with him.—JOSEPH JACOB.

THE SPURGE LAUREL.

SIR,—Since I was recently taken gently to task in THE GARDEN for describing Daphne Laureola as scentless I have diligently sniffed the blossoms at frequent intervals and under various conditions without success in detecting the faintest fragrance. The discussion has brought me several letters on the subject, among them one from a friend which settles the question as far as I am concerned, for I know him to be a careful and experienced observer. He tells me that he was surprised to read my statement that the flowers of spurge laurel were scentless, because he thought that he had enjoyed their fragrance in the past. He asked his gardener whether they had any perfume, and he replied that they were very sweet. He then gathered some of the flowers, found them scentless, and so they remained throughout the evening after being brought into the house. About a fortnight later, on May 15th, my friend was taking an evening stroll through his grounds when he perceived a deliciously fragrant scent, which he traced to its source in a bush of Daphne Laureola. I accept this without hesitation as proving that I was wrong in describing this plant as scentless; but I think it is clear that the fragrance is intermittent—so intermittent as to lead such trained observers as Bentham, Sir Joseph Hooker and Mr. W. J. Bean to record it as scentless. Can it be that the fragrance coincides with the ripening of the pollen or the condition of the stigma?—HERBERT MAXWELL, *Monreith*.

THE PROPAGATION OF CHOISYA TERNATA.

SIR,—Seeing there is so much controversy about Choisya ternata in THE GARDEN, I am enclosing herewith a chart which will possibly prove of interest to the readers of your paper who have had difficulty in propagating this plant. You will observe that only during four months of the year have cuttings failed to root. These cuttings were inserted in a cool sand frame with an average temperature of 48° Fahr.—L. B. STEWART.

SEDUMS.

SIR,—With reference to Dr. Lloyd Praeger's recent article on sedums in THE GARDEN, would not it be possible to arrange for an exhibit at Chelsea, or one of the Royal Horticultural Society's other shows, of some of his or other people's sedums in their proper classifications? It would be of the utmost value. As a New Zealander I have been trying to follow out his classification, but can only get a very small way.—N. R. W. THOMAS, *Antrim*.

COLOUR SCHEMES.

SIR,—I always enjoy reading in THE GARDEN of other peoples' colour schemes, and now I am so delighted with one of my own that I am sending it to you so that you may prove it. So few people grow or care for the purple wallflowers and I usually find when offering to my friends in the autumn any surplus plants, they say, "Thank you, but I have plenty of gillies"; not realising what a lovely bowl they make when mixed with forget-me-nots and a few sprays of the crimson Brompton stock, and they are even more beautiful by lamplight. Also, for filling in a bed of grey, pink and purple it is very good. In a border with a wide front edging of stachys with pink tulips and drifts of the crimson aubrietia the purple wallflowers fill in all bare places; yet the crimson aubrietia and Brompton stocks are usually difficult to place successfully.—ANNIE JONES, *Worcestershire*.

FRUIT PROSPECTS.

SIR.—Throughout a wide district in Southern Hants there is a profusion of blossom on the apple and cherry trees. Pears, where they escaped the close attention of the bullfinches, are also well clothed with flowers. Gooseberries, red and white currants, also raspberries and loganberries, are very satisfactory and, being late, may escape serious injury from frosts. In some districts the bullfinches practically cleared all buds from pears and gooseberries in about one week. The lilac buds shared the same fate in many gardens. Strawberry blossom is late, but strong, and the foliage is well up, forming in some instances a natural protection against frost.—HANTS.

HELENIUM CRIMSON BEAUTY.

SIR,—A new Helenium—following upon the traditions of its family and named Crimson Beauty, thereby giving an indication of its flower colour—is by no means a plant to pass by, especially if you are fond of dense colour masses towards the front of your border. This will not disappoint you from whatever aspect you view it, for it is of the cut and come again order and will provide you with sheaves of flowers for cutting, in addition to the splash it makes where it grows. In height, Crimson Beauty is about 2ft. and bears masses of flowers of a rich ruddy crimson that are curiously shot with gold.—SANDSTONE.

OBITUARY

E. A. MERRYWEATHER.

ERNEST ARTHUR MERRYWEATHER has passed away. He was known as "a real good sort" to those around his family hearth, to those around the larger hearth of his father and to an ever-widening circle of friends, which, like the circles caused by a stone thrown into a still pond, went on ever widening until it embraced horticulturists of the Continent and America.

He was born in 1872, educated at Southwell Minster Grammar School, served two years with Messrs. Hurst of Houndsditch, but gained most of his nursery experience on the nursery of his father, who still lives and takes an active part in the business.

His social activities in his native town were many. He has held all the principal

THE LATE E. A. MERRYWEATHER.

offices in the Parish Council, the Southwell Traders Association, the Southwell Rural District Council, the Board of Guardians. During the war he was Commandant of the Men's Section of the British Red Cross, and worked constantly at the Burgage Hospital. Such an array would have been sufficient for most men, but his horticultural offices were even more extensive. He was a member of the R.H.S. Fruit Committee, on the Council of the Chamber of Horticulture; ill-health had only prevented him accepting the position of president of the Horticultural Trades Association. He was an active member of the National Rose Society, and was always in request as a judge of fruit and roses both here and on the Continent, and will be known for years to come as the raiser of the roses Henrietta, Crimson Chatenay and Mary Merryweather, all roses of sterling worth, the first named still holding a position in the front rank and obtaining a gold medal at Bagatelle. This is a record that any man could be proud of and few attain, and to a man who acted on the proverb "Silence is golden" and had no publicity agent either in himself or anyone else, is a record that will keep his memory green, a memory that will be a proud one for his relations and friends.

He was buried at the historic Southwell Minster, being followed by all the employees, the principal residents of the town and many representatives of the various horticultural societies.—RICHARD PINCHES.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Celery.—During the present month the main crop of celery should be planted in trenches. Lift the plants with a good ball of soil, and get them planted at once to prevent the roots becoming dry. When the work of planting is completed, well water the trenches, and afford a little shade if the weather is hot. Pea sticks or a few branches of evergreens are excellent for this purpose. An occasional dusting of soot will stimulate growth and hold in check the celery maggot.

Peas are making good headway, and the soil between the rows should be hoed occasionally, while a liberal sprinkling of wood ashes will be beneficial if given during showery weather. A further sowing may be made, those sufficiently advanced staked, and the tall varieties mulched with manure or grass from the lawn. If the soil is dry, peas will repay an occasional good soaking of water.

Potatoes.—Keep the hoe going between the rows, and the soil may be stirred more deeply than for many crops. Those varieties that are ready should be earthed up without delay.

FRUITS UNDER GLASS.

Peaches.—In the early houses the fruits will begin to show signs of ripening, and at this stage it is advisable to discontinue the use of the syringe. A little damping down will still be necessary to hold in check red spider, but when the fruits are almost ripe it should cease. More air may be allowed, and both the front and top ventilators may be more or less open both day and night. If the weather is wet and cold, a little warmth from the hot-water pipes will be beneficial. There is a tendency in most gardens to overcrowd the peach trees, and in consequence much of the fruit is shaded with foliage. When such is the case, the leaves should be drawn away from the fruit, while a few could be removed, but not to any great extent. Later trees should receive attention, such as disbudding, tying in the young growth, and thinning the fruit. Keep the trees clean, and it should be borne in mind that the house should never be fumigated when the fruit is well advanced.

THE FLOWER GARDEN.

Aquilegias.—The long-spurred hybrids are a great improvement on the old columbine, and they produce a fine display in May and June. Seeds may be sown in the open ground in lines 1ft. apart, and directly the seedlings are large enough they should be pricked out, choosing an open site in the kitchen or reserve garden.

Staking.—The plants in the herbaceous border should be given some support before they are beaten down by wind or rain, and for general purposes the ordinary pea stick will be found the best. Little or no tying will be needed, and if properly carried out they will not be an eyesore. Gladioli are liable to injury during high winds, and for this reason each plant will require support. The same remarks apply to hollyhocks. Keep the border free from weeds, and any vacant spaces should be filled up with annuals.

The Pleasure Grounds.—Trees and shrubs that were planted late this season should be examined at intervals to ascertain if they are suffering from dryness at the root, and if so a thorough watering should be given, afterwards afford a liberal mulch of manure. Standard trees recently planted may need re-tying and the stakes making firm.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

New Potatoes.—The joy that is experienced over the first new potatoes from the garden should soon be forthcoming, and those who planted first earlies on a warm south border should have tubers ready for the cook. The Epicure is a fine first early, but is rather soft. If, however, it is left and dug up later in the season the tubers improve in texture and become drier. We have grown Epicure for a number of years and, although scheduled as a non-immune variety, it keeps free from all diseases. Pea pods on the Pilot should be filling up rapidly and a picking should be had shortly. Succession rows of peas should be staked, also seed of lettuces, radishes and spinach sown.

Carrots.—Lawn mowings are useful for spreading between the carrot lines. This will act as a mulch and so conserve the soil moisture in dry weather; it is also said to help in preventing the carrot fly from getting near the top portion of the roots. The mowings or short grass should be well pushed in and around the carrots.

Tomatoes.—Now is the time to top-dress the plants with some good loamy soil or partly decayed farmyard manure, when the trusses are heavily laden and the tomatoes swelling. All side shoots should be pinched out and the plants kept well supplied with water at the roots.

THE FLOWER GARDEN.

Roses.—The aphidæ or green fly family seem very partial to the rose. The Clensel spray, however—a quart bottle of Clensel to four gallons of water is a safe strength—will check their ravages and eventually clear the plants. This insecticide has a marked effect upon the foliage, as the leaves appear so healthy and decidedly more glossy.

Seedlings.—Dimorphotheca aurantiaca, Gypsophila elegans and Alonsoa Warscewiczii sown thinly in boxes some time ago should be pricked out now in the flower-beds. These plants are useful when set out between English or Spanish irises, and should brighten up the beds with bloom after the irises have gone out of flower.

THE HARDY FRUIT GARDEN.

Apricots.—When the trees flower freely and set well there is as a rule an over-abundance of fruits, which are usually borne in clusters. These should be further thinned out. Not only will the thinning relieve the tax upon the strength of the trees, but it will allow of more nourishment being supplied to the remaining fruits, and thereby we should get larger and better fruits. Liquid farmyard manure should be applied to the trees and, indeed, to all fruit trees bearing crops. Should green fly prove troublesome on the trees, spray with Clensel.

FRUITS UNDER GLASS.

Peaches.—There may be more than one variety of tree in the early house, and so one tree may be almost cleared of fruits, while another, such as Royal George, will be ripening. It is advisable, therefore, to suspend a net or tiffany underneath such trees so that any fruits which happen to fall will be secured undamaged. Trees cleared of fruit should be syringed daily if this can be done without injuring those bearing ripening fruits. Continue to train and tie in the shoots of later peach and nectarine trees.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Bouvardias.—Young plants propagated this spring should be potted on as they require it, stopping them at every second leaf to form a good foundation. They grow freely in a moist intermediate temperature. These plants are subject to attack by mealy bug, which should, however, be kept in check by a vigorous use of the syringe. The begonia mite also attacks these plants, so occasionally the sulphur vaporiser should be used. If so desired bouvardias may be planted outdoors for the summer months, lifting them during September and placing them in suitable sized pots, or if large quantities of cut flowers are required, they are best planted out on raised beds in a low pit. Bouvardias are so beautiful and useful that it is surprising they are not more generally grown.

Jacobinia chrysostephana, with its rich orange yellow flowers is very showy for flowering during the winter. If not already done, cuttings—which root readily in a warm case—should be inserted without delay. In common with most of the indoor Acanthaceæ this plant roots readily by means of internodal cuttings. In this case cuttings with two shoots can be used, which is an advantage with this plant as it is best when grown on without pinching; thus, where good specimens are required, it is best to grow three plants in a pot. This plant requires an intermediate temperature during its growing season, and requires careful watering at all times.

Jacobinia coccinea is another beautiful winter-flowering species that requires the same treatment as the foregoing plant. Both plants are subject to attacks by mealy bug and begonia mite, which should be guarded against. Both the species mentioned have a definite flowering season; whereas Jacobinia magnifica and its variety carnea will flower at almost any time, which is a distinct advantage as a batch of cuttings may be put in at any time they are available. The plants which grow freely in an intermediate temperature are very useful for furnishing the stages of the conservatory during the summer months. They also make fine large bushes where they can be planted out in a bed in the conservatory. The variety velutina is a much taller-growing plant, attaining a height of 6ft. to 8ft. when grown in 10in. pots; this makes it very useful for large bold groups.

Eranthemum indicum is a valuable winter-flowering plant, with beautiful blue flowers. It roots readily by means of cuttings at this time if placed in a case with slight bottom heat. During the summer it grows readily in a warm greenhouse, with a temperature of some 55° to 60°. Plants grown on for the second year make fine large specimens. If grown in a close, moist temperature this plant develops warty excrescences on the leaves and this can be prevented or cured by spraying with a rose-coloured solution of permanganate of potash.

Strobilanthes isophyllus is another useful winter-flowering plant which should be propagated by means of cuttings at this time. These will root readily in a close case. Cuttings root freely in an ordinary greenhouse during the summer months. The young plants should be pinched several times to induce a bushy habit.

Peristrophe speciosa is still another winter-flowering plant which should be propagated at this time by means of cuttings. This plant is a native of the Himalayas and grows freely in any cool greenhouse, its successful cultivation presenting no difficulty.

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2743 Saturday, June 14th, 1924 Price THREEPENCE

The Kelway Colour Border

is planned for continuity of bloom as well as colour effect. Your garden is of enduring beauty from early Spring to late Autumn, and so continues for several years, as a result of the minimum of cultivation, expense and attention.

These Colour Borders have evolved from many years of experience, and clients get the advantage of securing, amongst other subjects, the world-renowned Kelway Specialties in Hardy Plants.

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

We are only too pleased to advise.

WRITE NOW to the inventors of Colour Borders:

KELWAY & SON,

The Royal Horticulturists——LANGPORT

Barr's Bulbs & Plants

For Summer and Autumn Flowering.

GLADIOLUS, Large-flowered Choice Mixture, strong bulbs, per 100 **21/-**, per doz. **3/-**

GLADIOLUS Brenchleyensis (true), brilliant scarlet, strong bulbs, per 100, **21/-**, per doz. **3/-**

OXALIS lasiandra, bright rosy crimson flowers, per 100 **5/6**, per doz. **10d.**

CHRYSANTHEMUMS, hardy border varieties, single or double, fine named sorts, per doz. **5/6**

DAHLIAS, Double Decorative, Improved Single, Collarette, etc., strong well-hardened plants (descriptive list on application), per doz. **12/-**

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know this Booklet?

If you know it, there is no question at all about it; you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

ENCOURAGEMENT

"THE GARDEN" in its new dress has now been running for four months. We have received innumerable letters of congratulation, some so eulogistic that the Editorial staff have actually blushed with pleasure. We are delighted that THE GARDEN seems to satisfy its readers, for, after all, that is the aim of every journal.

One or two letters of criticism we have certainly received, and the criticism has always been that we cater perhaps a little too much for the advanced gardener. We hope that this criticism is not justified, for we make a sincere effort to supply information about every form of gardening and to satisfy every gardener, whether he has a small garden or a domain of many acres. In order, however, to allay any fears that subscribers, or potential readers, may have that we are ignoring the interests of the small gardener or beginner or young gardener, we are starting in this issue a new feature; this is a weekly page of simple gardening notes, dealing with matters of topical interest in gardens. These notes, which are written by an old and valued contributor who has had a long and intimate knowledge of gardening of every description, are entirely different from our "Gardening of the Week" columns, which give timely reminders of all work to be done during the week; rather do they take the form of paragraphs giving in simple and concise language full details of some gardening matter of immediate interest. Although primarily intended for the person whose knowledge of gardening lore is not equal to his enthusiasm, yet even the most learned exponent of this fascinating hobby will probably be able to glean useful information from the page of "Simple Gardening."

We are also delighted with the numbers of letters sent to us asking for information upon various gardening subjects. Their numbers are increasing week by week, which shows that the information given is of use. This exchange of correspondence is particularly satisfying, as it is of immense assistance to us in gaining that personal connection between paper and reader which we consider to be of such importance. We are always delighted to give all information in our power on any subject connected with gardening, however trivial it may seem.

On the other hand, our readers will understand the difficulties in the way of running a paper which we know to be good and hope to improve week by week. It will be of the greatest assistance if our readers could bring THE GARDEN to the notice of friends who may not be acquainted with or realise its merits. However much the circulation of a paper may increase, there is always room for additional readers, while the corollary is obvious; the more readers a journal has the better it will become, because there is more money to spend and so more information can be disseminated through its columns.

There is another way in which readers can help THE GARDEN, and incidentally advertisers and themselves, and that is by mentioning the name of the paper when ordering or writing about advertised subjects in our advertisement columns. A modern paper of high class is expensive to run, and a considerable amount of revenue is provided by advertisements. Advertisers are assisted by being able to judge the value of their advertising expenditure, while, as I mentioned above, the readers in the long run are the greatest gainers, because the larger the revenue of a paper the more information will be at their disposal.

This is very frank, but we feel that gardening and a love of plants is so intimate and so personal, that we are anxious to bring the paper in even closer touch with its readers. I hesitate to mention the word co-operation again, as it has been used so often in these columns, but there is no other word which expresses my meaning so well. E. H. M. C.

MR. W. J. BEAN.

We feel sure that all readers will join us in congratulating Mr. W. J. Bean, Curator of the Royal Botanic Gardens, Kew, upon the honour conferred on him by His Majesty the King, creating him a Companion of the Imperial Service Order.

Mr. Bean is one of our oldest and most valued contributors. For over forty years he has worked at Kew, during which time he has published his important work on "Trees and Shrubs Hardy in the British Isles" (two vols.), which is famous throughout the world. In 1917 the Council of the Royal Horticultural Society conferred the Victoria Medal of Honour in Horticulture—the blue riband of the horticultural world—on Mr. Bean.

LARGE-LEAVED SAXIFRAGES

THE MEGASEAS ARE PLANTS WITH HANDSOME FOLIAGE AND ARE EFFECTIVE AT ALL TIMES OF THE YEAR.

THE broad-leaved saxifrages of our gardens constitute quite a distinct section of this large and popular family, so different from all others that they have been accorded a genus all to themselves under the name of bergenia, but are more commonly known as megasea. From all other saxifrages they are recognised by their massive size and breadth of leafage, and most of them, being of an evergreen character, are very effective as hardy foliage plants at all times of the year. All are strikingly beautiful, with large trusses of rose, purple or white flowers in early spring. Some kinds, like S. ligulata and its variety speciosa, are so early as to be liable to damage by frost; but if judiciously planted in sheltered positions partly under low bushes of a deciduous nature they escape damage to a great extent.

One great charm of the megaseas is the rich and vivid autumnal and winter colouring of their foliage, SS. ligulata and purpurascens being especially rich and lovely with leaves suffused with crimson and brown among other colours. They are excellent for portions of the rock garden, where their evergreen leaves are of much value in furnishing during the winter, while from March to May the various kinds produce their large trusses of flowers in abundance. In the wild garden, planted in large groups, S. cordifolia and its numerous varieties are very handsome.

The cultivation of this group of plants is, with the exception of S. purpurascens, very easy, and they will thrive in almost any position, while not at all particular as to soil. On dry rocky ledges they are quite at home, and here they assume a much richer colouring in autumn than when planted in richer soil. They may be propagated to any extent by division during the autumn and early spring; every crown broken with a few inches of stem will grow. S. purpurascens and some of the newer Chinese forms require a moister position than the others and better soil. All the different kinds produce seed freely and may be easily increased in this way; the whole constituting a group of valuable foliage and flowering plants that deserve to be grown to a larger extent than they are at the present time.

All the megaseas have their home on the great mountain ranges of Central Asia, extending from the Himalayas into China and northward to Siberia. The distinct species are few in number, but they vary a great deal, and numerous forms have received specific names.

One of the most robust kinds, with large, handsome, evergreen leaves, is S. cordifolia, a native of Siberia which has been grown in gardens since the year 1779. The rosy red flowers are produced in large, dense trusses at the latter end of April, borne on stout stems well above the leaves. For planting in large masses in the wild garden or open woodland it is extremely valuable, making a most effective display with its beautiful flowers in spring and charmingly tinted leaves in autumn and winter. Also from Siberia comes S. crassifolia, which, although closely related to the above, differs by having obovate leaves that are not cordate at the base. It bears large panicles of somewhat pendent, rosy-purple flowers in April. On the whole, it is not so robust, but the smaller leaves assume richer autumnal tints. A plant known as S. orbiculare is a form of this, with somewhat rounder leaves; while S. pacifica is an earlier-flowering form. S. crassifolia is one of the oldest in cultivation, having been grown in gardens since the year 1765. A handsome plant is S Delavayi from western China, which grows from 9ins. to 1ft. or more high. It has obovate leaves that are olive green above and rich crimson on the under side. The pendent clusters of rosy pink flowers are borne on stout red-brown stems during the month of May. Forms of this species, which are found growing in moist rocky situations at elevations of over 12,000ft., are SS. Beesiana and yunnanensis. They are all closely related to the Himalayan S. purpurascens.

S. ligulata is a handsome Himalayan plant often going under the name of S. Stracheyi and one of the earliest in flower, so unless planted in a very sheltered position is liable to injury by frost. The leaves are not so persistent as those of the Siberian species, and it often loses nearly all of them during the winter. Under favourable circumstances, however, its flowers are very handsome and freely produced in large trusses in April. They are of good size, and pink or nearly white in colour. The plant is seen to best advantage in the rock garden, rambling on a rocky bank among the boulders. A more evergreen form or hybrid of this species, called S. ligulata speciosa, commences to flower in March, and as it retains its foliage the trusses of rosy purple flowers have the advantage of protection during the early stages of their growth. A distinct form of this species comes from Nepal and Kumaon, with very hairy leaves and almost white flowers. It is sometimes classed as a distinct species under the name of S. ciliata, but it is undoubtedly only a form of S. ligulata, which is found all over the temperate Himalayas from Bhotan to Kashmir, at altitudes of from 7,000ft. to 10,000ft. S. ciliata is less hardy than the typical plant, but under cover makes enormous leaves and produces large trusses of beautiful flowers.

S. Milesii is also a Himalayan plant, and is one of the latest in bloom, sometimes not flowering till the end of May. It is in the way of Stracheyi, but has much larger leaves and pure white flowers. From the same region comes S. purpurascens, a beautiful species that is not often seen in good condition. This may partly be accounted for by its affecting very high altitudes in the Himalayas, being found up to 15,000ft. above sea level. It owes its name to the richly tinted foliage it possesses, which is one of the greatest charms of this species. It has very pubescent

MEGASEA LIGULATA IS THE FIRST TO FLOWER AND SO REQUIRES CONSIDERABLE SHELTER.

Digitized by Google

panicles of nodding purple flowers in early June or sometimes in May. It likes a sheltered position in rich well drained soil.

One of the smallest megaseas is S. Stracheyi, with smooth obovate leaves and panicles of pure white or pink-tinged flowers. It is compact in habit and useful for the rock garden, and is sometimes grown in gardens under the name of S. afghanica, a totally different plant. Coming into flower early in April, it lasts for a considerable time in good condition, as the flowers are of good substance, little affected by the weather.

There are many hybrids in cultivation, chiefly the result of crossing S. cordifolia with S. purpurascens. They are all of robust habit, very floriferous, and several possess the charm of rich autumn colouring of the leaves. Some of the best include Brilliant, with large richly tinted leaves and purple flowers; Compacta, dwarf, rounded leaves and rose-coloured flowers; Distinction, dwarf, with large heads of pink flowers; Progress, very robust, with large trusses of rose-coloured flowers on tall stems; and Sturdy, more compact, with rose-coloured flowers. W. IRVING.

ONE OF THE MOST ROBUST SPECIES, MEGASEA CORDIFOLIA.

APHIDES OF THE FRUIT TREES

APHIDES ARE ONE OF THE GREATEST ENEMIES TO OUR FRUIT CROPS. THIS IS A SEASON OF THE YEAR WHEN THEY CAUSE GREAT DAMAGE AND SO HAVE TO BE FOUGHT WITH EVERY POSSIBLE WEAPON.

THE aphis, green fly or blight is an insect belonging to the Order Hemiptera and the family aphidæ, in which there are about a dozen genera with a similar life-history, which is peculiar and almost unique in the animal world.

Certain females of the aphidæ hibernate through the winter and others hatch in spring from eggs laid in the preceding autumn. In either case the insect, which commences its active life as soon as the warmth of the season permits, is a female and parthenogenetic, that is, she has no partner in the work of reproduction. In fact, no male aphides remain at that time. The female aphis at once starts her double life work. She feeds on the saps of her food plant and commences depositing eggs or young aphides on the stem, leaf or roots; at once if she has hibernated, and shortly if she has just come from the egg. Her newly hatched progeny in their turn commence to feed at once and delay but little before, in their turn, starting the work of celibate reproduction. Scientists differ in opinion as to the length of this delay, statements varying between two days and twenty. Temperature and species must be taken into account, but the rapidity with which a clean plant may be covered with blight from a few isolated aphides favours the general belief of a very short time.

Parthenogenesis, the rapid generation that requires but one parent, is the secret of the swift multiplication of the aphis. The parthenogenetic female is either produced alive or from an egg that hatches very quickly. It absorbs sap, growing rapidly for a short time, and then starts depositing eggs or young aphides. These repeat the same course for generations, till their host plant is getting overcrowded and some young females develop wings.

The winged forms seek new hosts and life goes on in the same way, wings only occurring occasionally till from some cause food becomes short. Then eggs are laid which hatch into the regular forms of male and female and a new cycle is started. This is generally in the autumn, and the new females lay eggs which remain through the winter and hatch in the spring, or hatch in late autumn. In either case the resulting aphides are parthenogenetic females. In the matter of hibernating, the ant is believed to interfere with considerable effect. It is said to carry certain kinds of aphides to its nest and supply them with food, especially in the case of those that can live on the roots of plants, as do the currant-root and elm aphis. The ant is also credited with placing out its aphides on suitable trees when the weather is fit. In fact, from close observation it is believed that, using the honey-dew, which the aphides freely distil, either as a food or a delicacy, the ant tends and cares for herds of aphides as carefully as humanity shelters and feeds its cows.

The aphis has six legs, a small broad and rotund body, a long beak for piercing the cuticle of its food plants and sucking up their sap, and antennæ, rather long and thin. On the upper part of the end of the body are two processes, known as cornicles, the use of which is disputed. It is confidently asserted by some scientists that they are tubes through which the aphis exudes honey-dew, while others think this is not so, but that the honey-dew is thrown out by the alimentary canal. Miss Ormerod considers the cornicles "additional means of excreting fluid."

She gives five "tribes" of aphis, of which the largest, aphidina (which includes the species attacking plums, apples, beans, etc.), and the shizoneurinæ (which contains the American or woolly aphis) are those chiefly affecting fruit trees.

The blue bug or rosy apple aphis (Aphis malifolia) does much damage to apples and pears, especially to the former. It sucks the sap from the buds and young leaves of the tree attacked, causing them to turn brown and produce gall-like growths. In bad aggressions the leaves will fall, as well as the greater part of the fruit. In colour this aphis is dark blue, grey or pink, and inclined to be mealy.

The green apple aphis (Aphis pomi) also affects the leaves and their functions, but less seriously; while the oat apple aphis (Sipho-coryne avenæ) does little harm to the leaves but sometimes attacks the fruit blossoms and causes some loss.

The leaf-curling plum aphis (Aphis pruni) causes curling of the leaves and unfits them for their ordinary functions

Digitized by Google

of digestion and respiration, occasioning injury to the growth and premature failing of the crop.

The mealy plum aphis comes later and does less harm except by distilling honey-dew, which clogs the stomata of the leaves and injures the health of the tree.

The hop damson aphis (Phorodon humuli) is hatched on the damson. Afterwards winged forms appear and migrate to the hops in May returning to the damson in autumn. They weaken the damson and on hops are dreaded as "the blight."

Currant and gooseberry aphides (Aphis grossularia) attack bushes from May, invading the younger growth and causing variously coloured blisters on the leaves, migrating when the winged forms appear to the lettuce and other plants, returning to their original host bushes in autumn.

Another species (Myzus ribis) affects currants and gooseberries later in the summer, blistering and curling the leaves; while Macrosiphum lactuca attacks currants, migrates to the lettuce, and returns to the currant in autumn.

The currant root and elm leaf aphis (Schizoneura ulmi) curls the elm leaves till late autumn when it may leave and attack the currant, gooseberry and other plants by infesting their roots, at which time it produces a woolly substance with which it covers itself. This, like other species of the schizoneura, has no cornicles. It is an insidious pest, and may easily be overlooked, so that in cases of bushes not doing well when no reason is obvious it may be advisable to apply remedies against it.

American blight, the woolly aphis (Schizoneura lanigera) appears like cotton wool stuck on a branch or twig. It attacks the wood of the apple tree, especially in places where it has been injured. The aphides are of a deep purple covered with a secretion looking like wool, but said to be wax. In winter they go down to the roots of the tree and return to the branches in summer.

In dealing with these pests the pamphlets of the Ministry of Agriculture will be found most practical, and thanks are due to them for some of the information used here.

The aphis needs to be numerous, for it feeds many hungry assailants. Tomtits dispose of a large number and the larvæ of many insects live principally upon it.

The larva of the lady-bird (family Coccinellida) should have our careful protection, though it is not always recognised as an ally. It is black speckled with orange. Its shape is a long oval pointed at head and tail. Stavely says it is like a little speckled crocodile. These creatures do much execution among the aphides and coccids or mealy bugs.

The lacewing (Chrysopidæ) in its larval state is also a diligent consumer of the aphis, as is the larvæ of Hemerobius. Both these are said to cover themselves with the empty skins of their victims. The hover fly of some species, both as larva and imago, is little behind the lady-bird in its voracious attacks on this pest.

In spite of their minute size some Ichneumon flies lay eggs in the body of the living aphis, the larvæ from which eggs grow to maturity upon the juices of their host. This may be seen occasionally motionless and dry-looking, and should be left that the useful ichneumon may hatch.

Remedies. — In the first place the natural enemies of the aphides should be encouraged and never destroyed if it be possible to avoid it. Lime wash may be applied early in the season.

Nicotine, pyridene, and paraffin may be used in conjunction with soft soap as a wash, which should penetrate curled leaves and other recesses. The admixture of soap with an insecticide makes it adhere to and clog the breathing holes of insects, and for this purpose the Rev. J. G. Wood recommends warm thick size to be painted on every patch of American blight, which if repeated daily for a fortnight he considers effectual.

Powdered tobacco or pyrethrum may be dusted on leaves, and where root aphides are suspected tobacco may be worked into the soil and will help to fertilise it.

In bad cases of root aphis on young stock it may be better to dig up and fumigate them, treating the soil with disinfectants before replanting. In addition there are several good proprietary insecticides.

Whatever remedies are used, special consideration should be given to the peculiar life habits of the aphis attacked, *i.e.*, if it be a leaf curler, an open sap-sucker or a root feeder, etc.

AMERICAN BLIGHT. CURRANT BLISTER APHIS. THE CAUSE OF AMERICAN BLIGHT.

NECTARINES AND PEACHES OUTDOORS

THESE trees are bearing good crops of fruit on walls outdoors, and the young growths are strong, clean and healthy. Disbudding, stopping where necessary and training the young shoots will need unremitting attention as the growth is more rapid. With care and forethought the winter pruning should be reduced so that very little will be required at that time. Examine the trees at short intervals and gradually reduce the number of the young growths until only just sufficient are left to fill up space and to replace any that have borne fruit this season which can well be spared to prevent overcrowding of the branches. When disbudding, retain the best young growths as near the base of the older wood on the upper side as possible, and others at intervals of a few inches. I make it a practice to tie early—that is to say, as soon as the young shoots have grown 3ins. or 4ins. in length. I place a tie about 2ins. from the base round the old wood and draw the young piece down towards it, which prevents an elbow at this point that would otherwise occur if the tying were left till the wood got harder and more brittle. For this early tying very soft damp raffia should be used, and great care taken not to injure the tender bark as the work proceeds. Retain the best leaders for building up an even, balanced head of all young trees that have not covered the allotted space, securing these at intervals neatly to the walls or wires before being damaged by rough winds, etc. When tying allow each shoot ample room in the ties for the growth to extend, as the fruits swell. Keep the foliage free from insects by repeated applications of nicotine wash or some other approved insecticide, not too strong at the first application. Do not overcrop and keep the roots well supplied in dry weather with water and liquid manure where the crops are heavy. With a little care and attention good results will follow.

SIMPLE GARDENING

ARUM LILIES.

WE know how very effective these noble-looking flowers are in our greenhouses and conservatories, yet many cultivators do not obtain the best from the plants. It is at this time of the year that wrong treatment is frequently given—in other words, the plants are sadly neglected. When the flowers have faded and the leaves begin to sear, the plants are placed outside and allowed to become dust-dry. This is wrong; they should be placed upright and water gradually withheld from those that are to be dried off. Some may be planted out in an open border, kept growing throughout the summer, and then lifted and repotted early in September. Those retained in pots may be treated in two ways: one batch will require repotting in new compost in August, another batch to be top-dressed only in August. In the latter case it is advisable to turn out each plant and see that the drainage is sound. The best compost for a surface dressing is that made up of fibrous loam, a small quantity of leaf-soil and bonemeal. It is, also, a sound compost for full repottings. Complete rest for the roots will be secured by laying the pots on their sides from July 1st to August 15th. When repotting is done the plants may be separated. In the case of those planted out they should be separated at the time of planting, not when they are lifted. The top-dressed plants will flower first, the fully repotted ones next and the lifted specimens a little later.

CUCUMBER CULTURE.

I know how very successful some amateurs are in growing cucumbers and that many others fail. It is more difficult to succeed with plants in houses than with those in frames, so I strongly advise frame culture to start with; then make a trial with plants in houses next year. The cucumber plant requires a light rooting-medium and a consistently moist one. A layer of soil composed of fibrous loam and leaf-soil in equal proportions 1ft. deep on a bed of cool rotted manure will prove more successful than a thin layer of heavier compost on a dry bed of litter. It is a mistake to attempt to grow many plants in a small space. One plant is sufficient for a single-light frame, but three may be grown in a double-light one. Plant on a little mound of soil 4ins. higher than the normal level of the bed. Do not forget to shade from bright sunshine till the plants are well established. Cover with mats on cold nights, but remove them early the next morning. Where there is no steam from the hot-bed the lights should be closed at night; if there is steam, a small opening at the top of the frame will allow all rank gases to escape. The ventilation should be increased early and gradually every fine morning. Syringe with tepid water when closing the frame on warm afternoons. Allow the leader to grow 18ins. long, then stop it; the resultant side shoots should be stopped at one joint beyond the young fruits forming, and so on till the frame is filled.

WATER LILIES.

It is not too late to plant water lilies in ponds and tanks, and if the work is carefully done, the plants will succeed. They should be purchased growing in pots, shallows or baskets ready for placing in their permanent quarters. Where there is mud in ponds it is a very easy matter to sink a few old turves from 18ins. to 2ft. 6ins. below the water level, according to the kind of lily planted, and thus make a firm bed for the plant to rest on and also prevent it sinking too low in the mud. In the case of artificial—constructed—tanks, a fair bulk of good old loam in addition to the turves will be required. The whole of the bottom of the tank should be covered with the loam to a depth of 8ins., and the whole turves placed in small heaps where the plants are to grow. Gently lower the plants and place a few old bricks on the baskets or beside them to prevent displacement. Nymphæas are general favourites. Many bog plants may be grown in pots, the latter being placed in large saucers containing water. Alisma (water plantain), Acorus Calamus (sweet flag), Hottonia (water violet), Juncus (rush), Menyanthes (bog bean), Peltandra virginica (water arum) are a few suitable kinds.

ZONAL PELARGONIUMS FOR WINTER FLOWERING.

The successful gardener must look ahead and make preparations according to requirements. In the case of these plants it is necessary to do so quite a year ahead to ensure good plants from the time of inserting cuttings, and from six to nine months where young plants are purchased. The early stages of the growth of the plants being accomplished under glass, open-air treatment is essential from mid-June to mid-August. The final potting should be done while the plants are under glass, preferably in a frame, then there is no risk of a serious check when the plants are placed outside. Compactly grown sturdy specimens should be the aim of the cultivator, and such can be obtained by placing the plants on a bed of cinder ashes, tiles or boards in a sunny position sheltered from the north and east winds. All flower-stems should be removed regularly while they are small and the tip of the centre or leading shoot pinched off to ensure a well formed bushy plant. It may be necessary afterwards to stop some of the leading shoots also. Very careful watering is essential and also feeding. Bone-meal in the potting compost is very helpful, and weak soot and manure water in a clear state at every alternate watering after the pots are filled with roots. Amateurs should be sure to include some single-flowered varieties in their collections, as the blooms do not damp off as readily as those of the double sorts.

TEMPERATURES AND VENTILATION.

The time of the year has come when the regulation of temperatures by judicious manipulation of the ventilators and lights on pits and frames will call for much thought and action on the part of the cultivator. I will, first, refer to the ventilation of the greenhouse and conservatory, as both kinds of structures require almost identical treatment. More moisture may be needed in the greenhouse where plants are growing for the purpose of furnishing the conservatory with flowers; but if the greenhouse is to contain also the flowering plants, then the treatment should be the same as that required by the conservatory. While the plants are growing towards the flowering stage more moisture may be maintained in the structure. When the flowering stage is reached a more buoyant atmosphere and a lower temperature are advisable. Tomato houses require this treatment; cucumber and melon houses—except when melons are ripening—should be closed in the afternoon with a really moist atmosphere within. Grapes and peaches, while their fruits are swelling, need similar treatment. Seedling and young plants in frames require very careful handling in every way, but especially so as regards ventilation, as the small air space is subject to extreme and sudden changes. The increasing and reducing of ventilation should always be done gradually both morning and evening. For the benefit of growing plants a rising temperature means an increase of atmospheric moisture, and the latter is supplied by the sprinkling of water from a syringe or rosed watering-can on the borders or paths and bare walls of a house, especially so in the case of forcing houses.

WINDOW-BOXES AND BASKETS.

These, when suitably filled, enhance the charm of a lovely garden and dwelling-house. It is very important that suitable plants be used. Ferns will not be a success in a hot corner, but petunias, nasturtiums, zonal pelargoniums marguerite daisies, lobelia and antirrhinums will. In the partially shaded windows fuchsias, lobelias, stocks, asters, Clarkia elegans and heliotrope will do well; while in the windows with north, north-east and north-west aspects ferns, pansies, violas, Nicotiana affinis, the night-scented stock and Virginian stocks will thrive and flower freely. In the intermediate windows both fibrous and tuberous begonias will grow luxuriantly. As the space is limited the soil used should be of good quality. Suspended baskets should be well lined with live moss, the latter pressed firmly to the sides. Peat and leaf-soil soon become dry and should not be employed. Good fibrous loam is the best. It is a good plan to soak the whole basket in a tub or cistern of water weekly to ensure the whole soil being moistened. Ivy-leaved pelargoniums, fuchsias, nasturtiums, begonias, and single-flowered petunias, are good basket plants.—GEORGE GARNER.

CORYLOPSIS GOTOANA

BY E. H. WILSON,
Of the Arnold Arboretum.

CORYLOPSIS are pleasing shrubs much too rarely seen in gardens. The best known are the Japanese C. spicata and C. pauciflora, but in recent years several new species have been introduced from China and there is one, or possibly two, from the Himalayas in cultivation in a few English gardens. All have delicately fragrant yellow flowers borne in pendent catkinate racemes or spikes.

The hardiest of the genus is C. Gotoana, which is native of the rugged mountains of central Japan, where, in 1905, Professor J. G. Jack collected seeds which he sent to the Arnold Arboretum. Our largest plant is now some 10ft. high and 12ft. through. It is a wide-spreading, much-branched twiggy shrub with the habit of a hazel bush. The flowers are lemon yellow, borne in catkinate racemes, each from 1in. to 1½ins. long, and have a pleasing fragrance suggestive of cowslips. It is a very free-growing, floriferous plant and one of the first shrubs to blossom in the spring. The flower-buds have never suffered winter injury in this Arboretum. The individual flowers are rather small, about ⅜in. across, with prominent glands rich in honey. The flower-buds of its fellow-countrymen C. spicata and C. pauciflora, which are native of Kyushu, the southern island of Japan, unfortunately, suffer more or less each winter, and as a rule those of the Chinese species are all killed. Corylopsis is purely an east Asiatic genus, being distributed from the Himalayas through western and central China to Formosa and Japan. No species is known from northern China, Manchuria or Korea.

CORYLOPSIS GOTOANA, 10FT. HIGH BY 12FT. THROUGH, IN THE ARNOLD ARBORETUM. From a photograph taken in April, 1923.

CORYLOPSIS GOTOANA WITH LEMON-YELLOW, FRAGRANT FLOWERS.

The best of the genus where properly hardy is C. pauciflora, with wide open flowers ⅜in. across and larger than those of any other species. Its name is not only a misnomer but also a gross libel on a very free blooming and charming shrub.

A NOTABLE BROOM

THE great charm of Cytisus scoparius pallidus, Moonlight Broom, does not seem to be as widely appreciated as it deserves to be; for, while one often sees most others of the scoparius set, a plantation of pallidus, or even a single specimen, comes as a surprise. The flowering of this form is contemporary with that of the common type, but the blossoms of pallidus are not only very distinct in colour—being a soft ivory-yellow, tending to cream in full sunlight—but they are exceptionally large and of a firm, almost waxen texture. The habit of the plant is also good, the bushes being less inclined to legginess and more compact than those of the type, and they are certainly longer-lived. For the half-shade of woodland this is the most desirable of its class, the self-colour and peculiarly delicate tint harmonising more pleasantly with natural surroundings than does the dapple of reds and yellows of the Andreanus section.

It is when the above, including the type species, are in full flower, as well as later on, that one realises how much we owe to Mr. T. Smith of Newry for giving us his late-blooming forms of scoparius. For while the former are to-day full of colour, the latter are as green as they were in mid-winter. It will not be until well after midsummer that these bushes will break into bloom, and I have seen them with a good show of blossom as late as August. These late brooms are, moreover, much sturdier than the type usually is. We have some old specimens 8ft. or more in height, with trunks as thick as a man's forearm, and they are heavily canopied by a robust growth of long and very leafy branches which produces a most imposing and gorgeous effect when laden with blossom as they always are. Late brooms may, it is good to know, be raised true from seed (always the best way with the members of this genus), but it is, of course, desirable always to gather the pods from the last to flower.

A. T. JOHNSON.

WALL PLANTS

BY SIR HERBERT MAXWELL, BART.

ONLY those who, like myself, are sufficiently stricken in years to have witnessed the successful revolt against formal bedding out, led by Mr. William Robinson early in the 'seventies, and rendered effective by the example set by such enthusiasts as the late Dr. Lowe, Miss Frances Hope, Canon Ellacombe, Mr. Wolley-Dodd, and a few others—only those, I say, can fully realise the vast advance in well-nigh every branch of outdoor flower-gardening that has taken place within the past half century. It has resulted in a corresponding increase in the number of those who take intelligent interest in the cultivation of hardy plants. One garden is no longer the replica of its neighbours; one never can tell what fresh surprise may claim his attention in the borders of other amateurs.

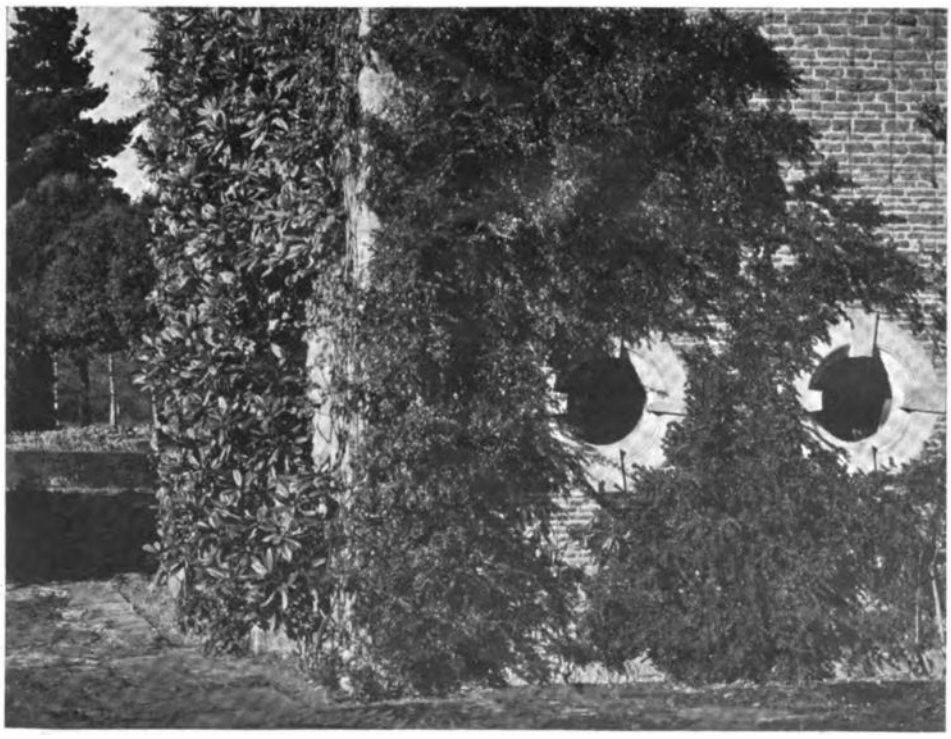
Howbeit, one branch of flower-gardening has lagged considerably behind the rest, and deserves better attention than it has received hitherto. We do not, as a rule, make the best use of wall space for training plants; indeed, one sometimes comes across cases of positive abuse of valuable opportunity in this respect. For instance, it is but a few weeks since I saw in a southern English county Berberis Darwinii carefully trained against the wall of a beautiful Georgian manor house. The said wall being of fine mellow brickwork, the flaming orange bloom of the barberry caused excruciating discord. Moreover, the training had been effected by nails and shreds, most injurious to the masonry. Less damage might have been done by the use of horizontal wires strained by a raidisseur through galvanised iron wires; but the simplest and safest method is to fasten against the wall upright staves of the height required, painted or creosoted, nailing across them large-meshed wire netting.

Leagues of stone and brickwork that might afford support and shelter to choice plants are covered with ivy, ampelopsis (Vitis inconstans), rambler roses and such like, good enough in due measure, but rendered wearisome through repetition. Once established, it entails strenuous effort to dislodge them, but one that it may be well worth undertaking, forasmuch as the protection afforded by a wall, especially a brick wall, will not only enable many plants to thrive that would succumb to a British winter in the open, but will enable many hardy species to develop a display which they could never attain to without such support.

CARPENTERIAS AGAINST A SUNNY SHELTERED WALL.

A good case in point is supplied by the Cape figwort—Phygelius capensis, which, although it may be grown as a border plant in most parts of our country, is of untidy sprawling habit in such a position, and troublesome to its weaker neighbours by reason of its subterranean runners; whereas, when trained against a sunny wall it rises to a considerable height, decking its shining evergreen foliage in late summer and autumn with innumerable candelabra of scarlet tubular flowers, in such profusion as I have never seen it do except as a wall plant. As there is a dingy brick-coloured variety of this brilliant shrub, it is well to obtain it from a trustworthy source.

Among hardy climbing plants there are very few that will support themselves against a wall by aerial roots like those of ivy, or by viscal discs on the tips of the tendrils, like those of the Virginian creeper and a few other species of vitis. At the moment of writing I can think of only five others—namely, Tecoma radicans and T. grandiflora, Hydrangea petiolaris, Schizophragma hydrangeoides and the dangerously poisonous Rhus Toxicodendron. It is simply amazing that the two species of tecoma, whereof the American T. radicans is the hardier, should be so seldom used for covering walls, seeing that they have very few rivals in splendour of autumnal blossom.



COTONEASTER AND MAGNOLIA AS DRAPERIES FOR A HOUSE WALL.

Digitized by Google

(In passing this reflection upon the discrimination of amateurs, my own withers are sorely wrung; for, to my shame be it said, I have neglected to assign space for these brilliant climbers.)

All other climbing plants must be provided with such support as will enable them to clothe a wall. They take advantage of it in one of three ways: (1) by twining their stems round the support from left to right, as in the common honeysuckle, or from right to left, as in lapageria; (2) by clasping the support with their petioles or leaf-stalks, as in clematis and tropæolum; and (3) by sensitive tendrils, as in the passion flower and lathyrus.

1.—In the first group may be noticed the Chinese honeysuckle, Lonicera tragophylla, the showiest of the genus, but scentless. It requires a shady aspect or a north wall, being liable to attack by aphides if planted in a sunny exposure. Polygonum Baldschuanicum is a twiner of enormous vigour, requiring ample room in height and breadth, for which it makes a liberal return with clouds of rose-tinted blossom. In mild districts there is no more charming drapery for a north wall than Lapageria rosea, which is much hardier than it gets general credit for, but is somewhat difficult to establish, owing to the insatiable partiality of slugs for the tender shoots that it pushes up from the root. These pests should be warded off by a guard of perforated zinc placed round the plant when first set out. No recommendation is required for that famous twiner Wistaria chinensis or the even finer W. multijuga, and no finer mantle for an entire gable can be devised, the only difficulty is to find room for these giants among climbing plants.

2.—In the clasping group are included many species and innumerable garden varieties of clematis. Among the former, there is none to surpass C. montana with its rose-tinted variety rubens and a later flowering variety Wilsonii. In mild districts C. indivisa lobata from New Zealand and C. Armandi from China make a fine display; while C. Flammula fills the autumn air with the fragrance of hawthorn. The garden varieties of C. patens, lanuginosa, florida and Jackmani do best as wall plants when planted so as to run through shrubs trained on the wall. They like rich soil and lime, but although they flower most freely in full sunshine, their roots should be shaded by other plants.

Solanum jasminoides climbs by clasping, and is well worthy of a place on the wall of a dwelling house, where, if the climate permits, it will be liberal of its charming clusters of white flowers; but it is only a plant for specially favoured districts.

3.—Climbers by tendrils give us a few choice things for walls, among which the passion flower, Passiflora cœrulea, takes high rank for beauty, demanding all the sunlight that it may be given. Personally, I prefer the blue-flowered type; the so-called white variety Constance Elliot being merely its washed-out replica. Two other South American climbers

A MOST GRACEFUL WALL PLANT. CEANOTHUS RIGIDUS.

CLEMATIS ARMANDI MAKES A FINE DISPLAY.

Digitized by Google

claim notice in this group—Eccremocarpus scaber, with tubular flowers painted scarlet and yellow, easily raised from seed which it ripens in abundance, and Mutisia decurrens, with large flowers of glowing orange, as difficult to propagate as the other is easy, but well worth any pains bestowed on it. Botanically it belongs to a very interesting genus—one among the enormous family of Composites, whereof very few aspire to climb, and mutisia is the only one that does so by tendrils. It is even more difficult to establish in the open than to propagate by cuttings. I must have planted out a dozen or more at various times, and only succeeded with one, now about fifteen years old, running up through Cotoneaster horizontalis on a wall to a height of 10ft.

4.—This group, consisting of plants which are in no sense climbers, includes almost any shrub or small tree that one may fancy for training on a wall. Small! did I say? There are two houses in my neighbourhood against which Eucalyptus Globulus has been trained, it may be hoped, with better hygienic than decorative effect. Again, at Keir, General Stirling's beautiful residence in Perthshire, the Italian cypress—C. sempervirens—has been put to singular use. It must be seventy or eighty years, perhaps more, since this tree, which would not survive a single winter in that inland district without the protection of a wall, was planted at regular intervals against the entire south front of the mansion house. Closely clipped, they stand as dark green cylinders, imparting a novel architectural feature to an otherwise plain façade.

These extreme examples are quoted as showing how wide is the choice of plants that may be used to adorn, or at least to clothe, bare walls. The wealth of subjects is indeed so varied as to be embarrassing. Among the most desirable for use where winter is apt to be severe the following species may be recommended. The evergreen Magnolia grandiflora and the deciduous M. conspicua, Jasminum nudiflorum and J. revolutum, the male form of Garrya elliptica, Forsythia suspensa, Lonicera fragrantissima (better than the very similar L. Standishi, but, like that species, flowering in mid-winter), Hibiscus syriacus in several varieties, Chimonanthus fragrans, Ceanothus rigidus, Buddleia variabilis var. magnifica (to be pruned hard back in spring) and B. Colvillei, the finest of the genus, Calycanthus floridus and C. occidentalis. For mild districts, including practically all the south and west coast of Great Britain, the Moray Firth in the north, and the greater part of Ireland, the choice may be greatly extended to include such things as the common myrtle, lemon-scented verbena, Carpenteria californica, Berberidopsis corallina Abelia floribunda, Clianthus puniceus, Tricuspidaria lanceolata, Abutilon megapotamicum, Fuchsia fulgens and other species. Beautiful effects have been obtained by planting Camellia reticulata on walls facing north, an aspect and situation which enables several of the more tender species of rhododendron to flourish, such as RR. Edgeworthi, bullatum, fragrantissimum, etc. It is well to remember that the soil at the base of a wall is apt to contain mortar rubbish, which is deadly to most rhododendrons. In planting them in such a position the old soil should be dug out and replaced with a lime-free substitute. Here it may be noted how seldom one sees full advantage taken of a wall facing north, yet there are many choice plants that will pass the winter happily under its shelter that would perish if exposed to the alternation of frost and sunshine on a south wall. On the other hand, such delightful shrubs as the Australian bottle-brush—Callistemons speciosus and salignus—Solanum crispum, and the recently acquired Chinese Indigofera pendula, etc., require all the sun warmth that our cloudy climate may afford them.

SUMMER CARE of TENNIS COURTS and LAWNS

THE increasing popularity of the game of lawn tennis brings in its train greater need for skilful treatment and watchful care of the turf.

A firm, even base is essential to a good game, and players will always plead for rolling, and still more rolling.

The doctrine has been so long and so generally adopted that the way to create and maintain a perfect lawn is to mow and roll, and continuously mow and roll, that it is accounted heresy to dispute the wisdom of that course. The fact is, excessive rolling can do, and frequently does, serious harm to lawns, and in the case of tennis courts, hard trodden and severely tried throughout the summer months, the additional compression of the soil by constant use of the heavy roller has in reality a murderous effect on grass.

The horticulturist is well acquainted with the necessity and importance of loosening the surface soil between growing plants, and every student has learned that aeration of the soil is an indispensable factor in good cultivation, because access of air is necessary for the transformation into available plant food of organic and chemical substances in the soil. It is surprising how many people imagine that grass can grow and sustain itself on a soil so tightly compressed by the roller that there cannot be the slightest possibility of air entering the rooting medium; and when it is borne in mind that every time the mower goes over the grass it removes growth that has drawn a certain amount of nourishment from the soil, it should become abundantly apparent that not only is periodical replenishment of suitable nourishment necessary, but that a degree of porosity in the soil that will facilitate the natural process of chemical conversion is equally indispensable. The question is, how the natural requirements of the grass may be satisfactorily coupled with the demands of sport.

Many methods have been tried and are regularly practised, I will describe what, to my mind, is the most rational and effective course of procedure.

Our present theme is the "Summer Care of Tennis Courts and Lawns," and it has to be borne in mind that nothing can be done which will adversely affect the comfort of players or handicap their play.

There is no simpler means of dealing with a hard-worn tennis court than by perforating the turf. A useful implement for this task may be made by driving 3in. nails through a piece of wood an inch thick, so that the under surface of the board is furnished with perpendicular spikes 2ins. long at a distance of about 2ins. apart each way. A stout handle should be fixed in the centre of the upper surface of the board, and thus, by using the implement after the manner of a turf beater, the turf will be evenly perforated with holes made by the nails.

For large greens a spiked roller has been invented which can be drawn over the turf in the same way as an ordinary roller, the lawn being by this means regularly perforated at intervals of a little more than a square inch.

The perforations may be left open for a day or two, during which time air will find access to the root-run of the turf.

The next step is to prepare a top-dressing, which should consist of a good concentrated fertiliser mixed with several times its bulk of sharp, gritty sand, taking care that this contains no stones. The top-dressing may be evenly spread over the turf and vigorously brushed to and fro with a good birch broom. This will work the dressing into the perforations, which, however, will be only loosely filled, and it will be a considerable period, even though the roller be used to a reasonable extent, before a lawn thus treated will again become as "hide-bound" as previously.

As to what constitutes the best fertiliser for such a purpose, a great deal depends upon individual conditions. Many things will nourish grass, but some manures add to the coarseness of the rougher and stronger kinds, while some encourage the development of clover, not always a desirable feature of a lawn or playing green.

The best fertilisers for grass on a light, sandy soil are not always beneficial where the lawn lies upon a cold, retentive clay. Another point that the keepers of tennis courts have to consider is that nothing may be used during the playing season that tends to create slime or sticky deposits during showery weather, or dust during drought; otherwise new tennis balls will be quickly soiled, and players will suffer discomfort. Bone-meal, soot, chalk, fine loam or leaf-mould, any of which may be quite suitable for use in autumn when the lawns have a long period of rest before them, would be entirely out of place for summer. Choice of nourishment for grass at this season must, therefore, be confined to readily soluble, quick-acting tonics or stimulants which, if not immediately washed in by rain, can be dealt with by the sprinkler or hose-pipe.

A. J. MACSELF.

NOTES FROM CONTRIBUTORS

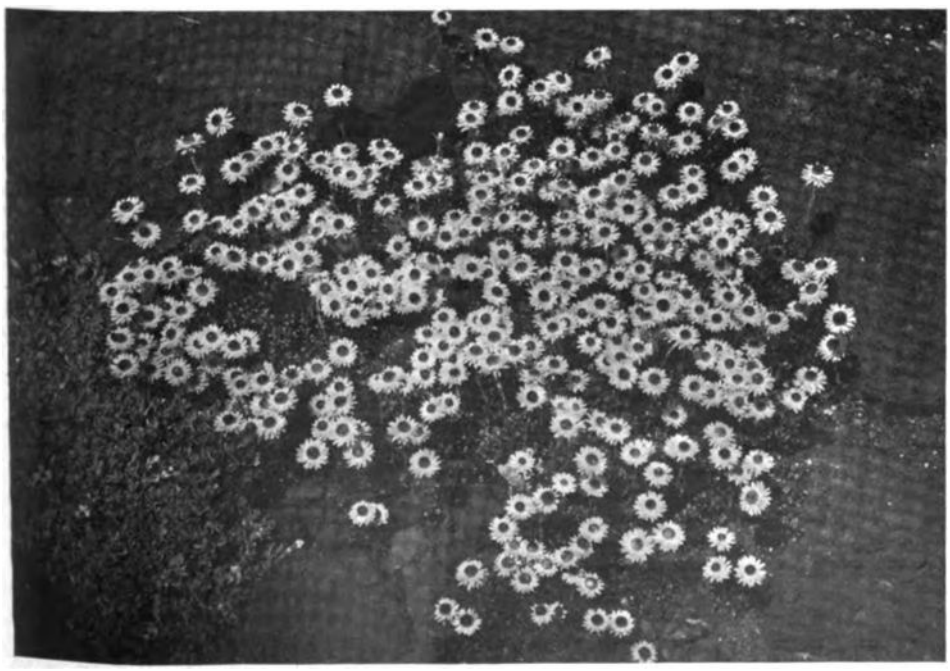
HELICHRYSUM BELLIDIOIDES.

THIS is a charming little everlasting flower for the rock garden, the small flowers being half an inch across with a double or treble row of clear white pointed floret rays surrounding a fluffy greenish yellow disc of florets in the centre. The heads are borne solitary on bracteate peduncles, which are covered by white cottony hairs, and from 2ins. to 4ins. high above the slender, prostrate, much-branched leafy shoots. The loosely imbricated, spreading or recurved leaves are from ¼in. to ½in. long, obovate-spathulate or obovate-oblong, and one nerved, the upper surface glabrous or slightly cottony, while the under surface is clothed with cottony adpressed tomentum.

It is a native of New Zealand, and is very abundant in the mountainous districts in the Northern and Middle Islands, ascending up to 5,000ft. According to Kirk's "Students' Flora of New Zealand," there appear to be two forms: erectum, which is found in the South Island, and which is rather a stout plant, with short, stout peduncles; and prostratum, which is found at Auckland and Campbell Island (and which Hooker in his "Flora of New Zealand" considers a distinct species, H. prostratum). In this form the heads are sessile and it has the receptacle more conical.

H. bellidioides appears to be perfectly hardy at Cambridge, having grown on the rock garden for a good number of years without any protection. It should be planted in the sunniest spot available in fairly dry and well drained soil. In such a position it flowers so freely that the open blooms completely hide the foliage during May. In wet localities it will be found advisable to place a sheet of glass over the plant during the winter months. It is a free grower and very easy to increase, as it spreads by means of underground stems. The trailing stems often root to the ground as they spread, while cuttings of the young shoots root readily if placed in sandy soil in a close frame.

Other helichrysums from New Zealand suitable for growing in the rock garden are H. Selago, an attractive and interesting species with a compact shrubby habit; and H. trinervum, somewhat resembling H. bellidioides, but larger in all its parts and having three conspicuous nerves in the leaves, whereas, as I have already mentioned, H. bellidioides has only one.—F. G. PRESTON, *Botanic Garden, Cambridge.*



A CHARMING EVERLASTING FOR THE ROCK GARDEN, HELICHRYSUM BELLIDIOIDES

A FINE CHINESE PLANT.

RHODODENDRON calostrotum, one of Farrer's introductions from Upper Burmah, is undoubtedly a dwarf rhododendron of outstanding merit. Last year I received a small plant from the R.H.S. under Farrer's No. 1045. I planted it straight out among heaths in a sunny position on the rockery, and it grew splendidly. This year it has eleven of its large rose-coloured blossoms about 2ins. across, which, as the enclosed photograph shows, appear very large for the size of the plant. It seems to be quite hardy, for although it only formed its flower-buds on second growths late in the summer, not a leaf was damaged during the past very trying winter.—R. B. C., *Northumberland.*

RHODODENDRON CALOSTROTUM.

SCILLA LILIO-HYACINTHUS.

MANY years ago, when one had much to learn, as one has still to do, there was a white-flowered bulbous plant in an old garden where it has been for generations, which was a puzzle to a group of those of us who were ardent lovers of hardy flowers. At that time I did not possess Parkinson's "Paradisus," where Scilla Lilio-hyacinthus is figured as Hyacinthus stellatus lilifolius, but by dint of diligent search I was satisfied that it was the white form of S. Lilio-hyacinthus of Linnæus, which was also well described by Philip Miller. This white variety is by no means plentiful in gardens, but in the old garden in question it so abounded that a good many bulbs had been relegated to the woods. I was delighted when I was given some bulbs from this garden, but, unfortunately, I appear to have lost them during a removal. All my clumps at present in flower are of the blue or typical form, a variable plant, but I am pleased to see them doing so well, and I trust in time again to acquire the white variety. The "Paradisus" mentions a pink form, which Parkinson had heard of but not seen, and Miller speaks of this "red" variety as in existence. I have never come across it, but it will probably be in existence in the Pyrenees, where S. Lilio-hyacinthus is said to be very abundant. I have been enjoying lately the flowers of my blue ones, which vary considerably in the closeness of the rather conical raceme showing well against the broad, lily-like leaves. They are generally of a pretty violet-blue, some with a pinkish tinge about them, and are very bright indeed in a shady border, where they are planted along with hardy ferns and other plants which grow well in shade. I found this scilla thrive well in sun also, but I think the colour is better and shows to more advantage in the shade than in the sun. Parkinson calls it "the Lilly leafed starr Iacinth," while Miller speaks of it as the "Lily-rooted Squill," from the bulbs being formed of scales, like those of a lily. It seems curious that this old bulb is but little offered, especially in these days, when wild gardening and profuse planting of bulbs in grass are so justly in vogue. It is well adapted for this purpose, especially in some wooded or partially wooded dell.—S. ARNOTT.

OXALIS ADENOPHYLLA.

THE Patagonian wood sorrel, Oxalis enneaphylla, is such a favourite with me that I cannot without reservation subscribe to the doctrine that the Valdivian wood sorrel, O. adenophylla, is more beautiful, although that is a view strongly held by some. It is true that the usual—and to me the finest—form of O. enneaphylla has pure white flowers. That is no defect in my mind. But apart from the question of colour, O. adenophylla may well stand on its own merits in point of intrinsic beauties. It is charming from the moment it appears above ground with its exquisite tufts of silvery grey leaves, looking as if daintily carved from almost dull oxidised silver. Then the consummation of its charms appears in its numbers of bright pink flowers, far prettier than those of the rose-coloured form of O. enneaphylla, of whose white form I am so fond. These flowers are wonderfully large and when open in the sun they are remarkably pretty. Even in the closed stage

Digitized by Google

they are of much interest from the manner in which the segments are arranged, waiting for the alluring rays of the sun to unfold and bestow upon us the full loveliness of the flower. In cultivation there is a great difference in the requirements of the two species. Whereas O. enneaphylla delights in the shade and is never really happy in the sun, O. adenophylla is a sun lover and its flowers rarely open except when that luminary shines upon them. This is, in some ways, a defect, but, on the other hand, the blooms probably last longer than they would do were they open alike in shower and sunshine. Then I do not think that O. adenophylla is so exacting in the way of soil, as it appears to thrive in ordinary light loam. Some find it difficult to cultivate, and its reputation in this respect is not a very high one, but possibly the failure to provide it with a sunny position is the cause of this failure. After all, one must try for oneself and if at all possible succeed, although it may be that success will only come by unorthodox treatment. There are many factors in gardening, and some of them are deeply obscure and cannot be diagnosed.—DUMFRIES.

HOLLY BLOSSOM.

NEVER in my lifetime (with observations over some forty years) have I seen such a wealth of holly blossom as this May. In the Bristol and Somerset district many of the bushes and trees are dull white with blossom; and it would be interesting to know if this is more or less general in Britain, particularly in regard to native specimens, *e.g.*, in the wild Sutton Park, north of Birmingham, where so many holly trees attain a considerable height.

Even more closely trimmed trees and hedges of holly have much blossom in places, as the finely kept hedge of holly skirting the park of Tyntesfield (Colonel George Gibbs, M.P.). These low holly hedges are on either side of the main road from Bristol and Long Ashton to Clevedon. Both are about a mile and a half long. I noticed that in some native Norwegian herbarium specimens of Ilex Aquifolium recently sent me for distribution, the leaves are much less spinous than those of the usual British form.—H. S. THOMPSON.

THE EDITOR'S TABLE

WE have received from the Welsh Bulb Fields, St. Asaph, North Wales, a beautiful box of Darwin tulips. The blooms were exceptionally well packed and arrived in excellent condition. On the desk where these few lines are penned is a large vase containing the soldierly-looking Darwins, and our minds can visualise those fields of these wonderful blooms in North Wales.

Here in our office are such noble Darwins as Farncombe Sanders, with its radiant splendour of cochineal red; the stately Boadicea, in orange-scarlet; Ronald Gunn of slaty lilac; the well known Clara Butt in soft salmon-pink; Ida Scott, a new sort decked in deep lilac—this should prove very popular; and Margaret, the outside petals of which are blush and the inside of the flowers soft pink.

LAWNS AND LAWN-MOWERS

A WELL known present day authority on lawns writes: "The scythe was an implement which required a very considerable amount of skill and concentration of energy to keep the turf to the required smoothness. With the lawn-mower the work is of a more mechanical nature and the lawns have suffered accordingly," and John Ruskin somewhere laments the passing of the scythe. This notwithstanding, there can be no doubt that the coming of the lawn-mower not only effected a great saving of labour and enabled the sward to be kept closer and more even than ever before, but had a highly beneficial effect upon the turf. No one to-day ever gives the scythe a thought as a practical alternative to the lawn-mower, but the selection of a suitable mower or mowers for one's greensward is a fairly important matter, sufficiently so at any rate to justify the following notes. For the large lawn, for the now so much appreciated wide grassy vistas through the pleasure grounds, for the fairways on golf courses and such like, the motor-mower has come to be a necessity. Practically the only remaining drawback to this class of machine is a tendency for it to destroy the turf in wet weather when turning, but this fault is almost confined to the large heavy machines which are provided with seats. The "nippier" machines which tow the man in charge at considerably above ordinary walking pace turn easily and neatly, and it is surprising what a lot of work a 30in. machine of this class will manage in a day. The capital outlay upon such machines is, of course very much smaller than upon the "leviathans."

The problem of the motor-mower has been tackled from both sides, so that these machines are made in this country by firms with many years' experience of "push" and horse machines and of steam-rollers and such like, and, on the other hand, by those who have made a study of the use of the internal combustion engine for purposes somewhat dissimilar. The results achieved are very similar in both cases, and to-day one can safely say that the British-made motor-mowers are as trustworthy mechanically as the British motor car, and what higher praise could be bestowed! It is advisable that the man who is to take charge of the machine should have its internal economy explained to him and be "put wise" as to the meaning of the various knocks and rattles which may possibly supervene in wear and the appropriate adjustments. It is not a bad plan to let a skilled chauffeur-mechanic give an eye to the machine occasionally. Some of the motor-mowers now being built are veritable feather-weights, but they appear to give excellent service and, of course, are better for the lawn in wet weather, though they do little to roll it when the turf is on the dry side. All things considered, perhaps it is wiser not to attempt to combine rolling and mowing in one operation, though the saving of labour thus effected is, admittedly, tempting. At least one firm of motor-mower manufacturers supplies (as an "extra") a very useful cultivating attachment which aerates the surface soil and is very beneficial to the health of the sward.

Are horse and pony mowers still called for? Undoubtedly, especially the latter. There are many places where the lawns are not very extensive and, apart from the mowing, an otherwise necessary pony would have insufficient exercise. Here a word of warning is desirable; get a mower a size too small for the pony rather than one a little too large, bearing in mind that however carefully kept, a mower hardly keeps in equal "tune" the season through. If the animal is worked without shoes, lawn-boots are not absolutely necessary, but shod or unshod, lawn-boots are a good investment and save damage to the turf.

Everyone who has a lawn should have at least one hand-mower. There are always corners and verges where motor—or pony—machines cannot work, while there are in this country thousands upon thousands of small lawns which must be cut by a push-mower.

There has long been a controversy as to the comparative merits of the roller and side-wheel types; each has its advantages. The side-wheel machines run much more easily, and when the lawn is dry do equally good work, but even with the Sladen subsidiary roller sold for the purpose, are not too satisfactory for cutting verges while they are apt to damage the turf when there has been a spell of wet weather. Many garden owners with an eye on labour costs keep both types, so that the most suitable machine may be available no matter what the weather conditions.

It will be noted that side-wheel machines are made to varying specifications and at very different prices. The more expensive machines have large driving wheels and rapidly revolving blades and, as a rule, ball-bearings. The cheaper types are, if British made, quite reliable, but are, naturally, a little less easy-running and need more adjustments than the higher priced machines. Some manufacturers go to great pains to make every adjustment as easy as possible, so that the use of spanners is only necessary under exceptional circumstances. Many find this a great convenience, but where there are small and possibly mischievous children it does not always work out satisfactorily.

The makers always seem to the writer just a little optimistic as to what constitutes one "man-power." The 12in. size roller machine is plenty hard enough for one man to push, and the same applies to the 15in. side-wheel makes, even when equipped with big driving wheels and fast-running knives.

Whatever type or make is chosen, see that the machine has fair play. On roller machines the cutting cylinder should be reversed occasionally, the knives being thus self-sharpening, but dents and chips caused by stones and such-like will not "self-sharpen" themselves out, and though the greatest care may be—and should be—taken to keep such off the lawn, every lawn-mower should be entrusted at least once a year to a properly equipped repairer for regrinding and overhaul. If there is no firm with proper plant locally, it should be sent to the makers

Digitized by Google

for attention. The best season to send in the machine for this straightening out is immediately cutting is finished for the season. The overhaul is likely then to be much more thorough than if the work be delayed until the machine is about to be wanted in the spring.

The yearly overhaul will not in itself, however, ensure a long and trouble-free life for the machine. Every type of mower needs careful cleansing after use, but cleansing does *not* mean a bass broom and the free use of the hose or of buckets of water. One does not risk getting water in one's watch or even in the gear-box of one's motor car; why risk it reaching the bearings of the mower? If the moving parts need cleansing, paraffin is the agent to employ; but if a fairly stiff brush and a thin strip of blunt-pointed hard wood (preferably box tree) be used diligently after each day's mowing, very little chopped grass or other débris should reach bearings or gearing. Oiling is very necessary, but if lubricant is used at all freely when the machine is about to start work, some of it may drip on to the grass and cause unsightly patches, which will, in all likelihood, need returfing.

After cleaning and before putting away is the best time to oil the machine; but some of the more important bearings—especially (on a hand or horse machine) those carrying the cutting cylinder—will need occasional attention during the day's work. A few spots only should be given at one time, and it is a help if one of the lubricants containing graphite be employed. If the machines are sent for overhaul immediately after the season's work is finished, little winter-care (other than keeping in a dry place) will be necessary, as the makers or qualified repairers will take the necessary precautions to keep the mowers free from rust until, in a surprisingly short while, they are wanted again for use.

FORTHCOMING EVENTS.

June 20.—Manchester and North of England Orchid Society's Meeting.——Eastbourne Horticultural Society's Meeting.

June 24.—Royal Horticultural Society's Fortnightly Meeting (two days). Lecture on the first day, at 4 p.m., by Mr. W. J. Dowson, M.A., on "Gardening in the Highlands of Kenya Colony."

June 25.—Morley Paxton Society's Meeting.

June 26.—Royal Botanic Society's Meeting.

CORRESPONDENCE

THE LEMON SCENTED VERBENA.

SIR,—I see in the issue of THE GARDEN dated May 24th, page 361, Mr. A. D. Turner says that noted gardeners have sometimes a difficulty in propagating the lemon-scented verbena (Lippia citriodora or Aloysia). My experience as a gardener in the north is that there is not the least difficulty in rooting this plant if the young wood is taken (either the thick or the thin wood), and in May and June one can get a strike of 100 per cent. In fact, last year a few of the tips which had been taken off to make the plant break back and had been carried about in my pocket for a few days were inserted, and out of twelve only two did not root.—L. B. STEWART.

NARCISSUS FORTUNE.

SIR,—I cannot let Mr. Jacob's criticism of this noble daffodil (page 338) pass without a word of protest. Mr. Jacob confesses that he had not seen the flower for a long time. That being so, it was hardly fair to judge by the wrecks of blooms on Mr. Guy L. Wilson's stand as they ought not to have been there, and I told the exhibitor so. I can hardly imagine anyone comparing Helios and Fortune. Helios as shown at Birmingham was at its very best, but if Mr. Jacob buys a few bulbs and tries to grow them, I think he will sing another song, and it will not be one of praise. I had Helios when it was about £13 13s. per bulb, and tried my level best to do it well, but the wretch never had any colour in the cup, though the foliage had lots of beautiful (?) stripes. After keeping it for several years and never seeing a well coloured flower I sent the stock into retirement and have never regretted the action.

Personally, I consider Fortune to be by far the finest giant incomp. in cultivation. When at its best it is a perfect flower, smooth in segments, beautifully proportioned, perfect pose and a stalk long enough to satisfy anyone. The Brodie of Brodie is reported to have said, "Fortune first, the rest nowhere." It seems a great pity to exhibit flowers that are far below par, better to let a season pass, or even two, than to set up flowers which are out of condition or are not at their best.

Another daffodil season has come and gone, and what an extraordinary one it has been: frosty nights, keen east wind and no rain for weeks together. Until the much-delayed rain fell we ploughed about in dusty sand about half an inch deep when working among the daffodils, and shoes and boots were quite unfit for the house until well cleaned. But when the rain at last fell, what a change! In less than a week the foliage grew and improved in colour, flower-stalks lengthened, and the flowers which during the drought had been very poor in size and quality now came quite up to standard; some, indeed, were extra good. Never do I remember a season when we had so many flowers per bulb. I counted one bulb of Empire with fourteen buds, and it was a bulb planted only last year—not a clump of two or three years' standing. This stands as a record with me, but sixes, sevens and up to eleven were quite numerous. A Dutch friend told me recently that he had over a thousand seedling daffodils under numbers, so it does not seem likely that there will be any lack of novelties for some time to come. Scrap the worst and make the most of the best is my advice.—J. DUNCAN PEARSON.

OXALIS ENNEAPHYLLANEVER!

SIR,—I am much interested to know the derivation and meaning of the second word above, which I see in your issue for May 31st, page 383. I cannot get further than nine-leaved. My nephew (a Public School boy), who fancies his Greek, translates it "In new leaf never."—E. R. BIGNELL.

[We regret that this charming plant was inadvertently renamed in our composing room during the few hours which we had at our disposal in which to get out our Chelsea number.—ED.]

MISTLETOE ON ROSE TREES.

SIR,—I read with interest Mr. Meade King's article in reference to above (page 343), and also the comments on same from readers in THE GARDEN for May 31 (page 389).

I do not think there is anything unique in the matter, as I well remember, when I lived in Devonshire, seeing quite a big spray of mistletoe growing out of an old Gloire de Dijon rose in the grounds of Dr. Domville, Northernhay, Exeter; and in another case, at the Rev. Hamilton Gell's at Winslade. Here, Reine Marie Henriette was the foster-parent. For years a very large spray lived on a Crimson Rambler in the private garden of Mr. Perkins (sole proprietor of Messrs. Wood and Ingram, Huntingdon) and was only cut down a short time ago. So that it would appear to be rather a common occurrence for birds to deposit (accidentally) the seed into a crevice of the rose tree.—GEO. WYATT, *Huntingdon.*

ROCK GARDENS AT CHELSEA.

SIR,—Last week I travelled over 250 miles to see the Chelsea Show, and I was well rewarded. But I want to express my feelings of great disappointment at the present style of the outdoor rock gardens exhibited there. I do not mean that they were not beautiful pictures, tastefully built, and showing great cultural skill in the plants that adorned them, but they are misleading and wrong. As a hybridist, I protest that such creations are a cross between an alpine slope and pure "bedding out," and the offspring is a "rogue" and should be treated as such.

Odd outlying stones are scattered on short grass in such a manner that a mowing machine is useless, and only expensive and laborious hand clipping can keep such grass in indifferent order; and then, on sundry rocky ledges or banks, colonies of some alpine plant are bedded out in a wonderful colour scheme. Anyone with a slight knowledge knows that this is constantly done in positions which are utterly unsuitable and in which such plants would never thrive, and even if they did, when their flowering season was over there would be a bare space or bald ledge for the rest of the year. For there is no suggestion of succession, and such a system produces a seven days' wonder at most.

A fine effect can be made by bedding out some frame-grown alpines under the shade of a small group of pines; they look delightful, but how misleading to those who seek to become students in the high art of alpine culture—how disappointing—what a short-sighted policy for the trade in future!

There is no attempt to clothe the rocks, no attempt happily to mingle plants and rocks naturally. The stones are treated as one thing and the plants as another. There is little or no attempt to instruct and educate a garden-loving public as to the best position and surroundings most likely to induce a plant to grow well. The whole erection is unnatural and misleading.

On a table under canvas one expects the artificial grouping of alpine or garden plants. They are exhibited for show, and show practices and show morality are wide and embracing; but surely it is possible and wiser to make a supposed alpine garden more natural and so more truthful, and enlist an army of new recruits who would become enthusiasts, whereas under the present conditions they obtain a false impression, and fall defeated and disheartened at their first attempt.—ERNEST BALLARD.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Asparagus.—As a general rule the cutting of asparagus should cease after this date, but owing to the lateness of the season there is no reason why it may not be continued for another week or ten days. Afterwards the plants should be allowed to grow freely, or next year's crop will suffer. Strong growths may be staked to prevent injury from wind and rain, while an occasional application of liquid manure will be beneficial. A light sprinkling of salt may be afforded about this date, while a dressing of bone-meal may also be given.

Runner Beans.—Many amateurs aim at procuring early crops, but sufficient attention is not paid to a late supply, hence the necessity for sowing a few lines of runner beans during the next week or two. Allow 6ft. or so between the rows, and 6ins. or 8ins. from plant to plant. This crop will continue until destroyed by frosts. The early sowing will need staking, and the hoe should be used freely between the lines.

Leeks.—The main crop should now be planted in trenches. If the weather is dry give the roots plenty of water, and add soil to the trench as growth proceeds. Another method is to make holes with a crowbar 9ins. apart and 18ins. between the rows. Drop the roots to the bottom and water in; nothing more being needed except an occasional hoeing which will gradually fill the holes with soil.

FRUITS UNDER GLASS.

The Orchard House.—Trees in pots will need copious supplies of water, and when the fruit is set the roots should be fed with liquid manure and some reliable fertiliser. The thinning of the fruits should be given attention, and all superfluous fruits removed as early as possible to help those that are left to form the crop. All young shoots except those needed for extension should be pinched at the fifth or sixth leaf, and here and there disbudding may be practised to prevent overcrowding. At this season plenty of ventilation is required, and when the weather is warm the top ventilators may be left open an inch or so throughout the night. Watch for insect pests and vaporise the house directly any aphides are seen.

THE HARDY FRUIT GARDEN.

Cordon Pears.—In many gardens pear trees have flowered profusely, and there is every prospect of there being good crops, but it is perhaps a little early to make a definite statement as many of the fruits will drop from various causes. However, directly it can be seen which fruits are swelling freely, a little thinning may be done, but the final thinning should be deferred until all fear of fruit droppng is past. Large-fruiting varieties such as Pitmaston Duchess may be thinned more severely than the smaller kinds of which Beurré Hardy may be cited as an example. In the meantime the crop may be assisted by pinching the side growths at the fourth or fifth leaf, and where the tree has not yet reached its allotted space the leading shoot ought not to be stopped for a few more weeks. Pinching the centre from the shoots should, like disbudding, be done gradually.

Strawberries.—This year the plants flowered freely and did not receive any injury from frosts. If not already done straw litter should be placed between the rows and the beds covered with nets before the fruits begin to colour. When the fruits are swelling the roots enjoy plenty of moisture.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbages.—Where these vegetables are highly esteemed and a regular supply required, the root stocks should be left in the ground after the hearts have been cut, as early cabbages, in general, are much later this year, and if the old stems are left they will soon break away into fresh growth, forming later on two, three and even more cabbages on each stem. Although not so big and well shaped as the primal heads, they will be of great service in the kitchen.

General Work will include more or less a good deal of cleaning in the form of hand weeding, hoeing and raking among the various vegetable crops. Likewise the thinning of beetroots, carrots, parsnips, salsafy and turnips raised from main crop and late sowings. The planting of succession Brussels sprouts, broccoli, borecole, cabbages, cauliflowers, savoys and leeks should also be forwarded. It is interesting to state that the leek is not over particular as to situation, provided the soil is well manured and cultivated. I have seen good leeks taken from a border whereon the crop had been regularly grown for seventeen years. Broccoli should be planted on somewhat firm and not overrich soil. A sowing of French and runner beans should be made.

THE FLOWER GARDEN.

Bedding Plants.—It is always good policy to keep a few bedding plants in the reserve garden, as blanks occasionally occur in beds and borders; plants get broken or sometimes die off from one cause or another. Plants in pots may, as a rule, be set out almost at any time, but all bedding should be completed forthwith.

Flower Vases.—There is no doubt that statuary and flower vases add to the beauty of the residential demeane when situated and placed so as to harmonise with the surroundings. If not already done the vases on terraces, etc., should be filled with their summer occupants, such as marguerites, ivy-leaved geraniums or fuchsias; for those who appreciate red there are still the old favourite geraniums or the dwarf single dahlia Coltness Gem, which seems at present to be putting the bedding geranium in the shade. It is not good practice to fill the vases with over-rich soil, or yet to leave it in a loose condition, as this would only tend to encourage leaf and stem growth on the plants instead of flowers. For small vases, plants in pots may be used and the pots hidden with moss or one or other of the low-growing saxifrages.

Staking.—If the spiral wires are used to support the carnation stems, no tying will be required; but should straight stakes be employed the stems should be neatly, securely, and regularly tied to them. Sweet pea growths which have got outside the wires and are likely to get broken should be tied. Pardalinum lilies, when grown in quantity and near other plants, sometimes require to be staked and tied in.

THE HARDY FRUIT GARDEN.

Strawberries.—A few fruits may now be showing colour, and no time should be lost in having the stakes put in and strings stretched, so that the nets when spread on will be kept 2ft. or 3ft. above the plants. It is much better to have the nets well above the plants than to have them spread out on the plants.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Euphorbia pulcherrima (Poinsettia).—About the middle of this month the propagation of this plant should be taken in hand. Young shoots about 4ins. in length taken off with a heel should be secured for cuttings, and to prevent excessive bleeding the cut ends should be dipped in finely powdered charcoal. The cuttings are best dibbled singly into small pots, afterwards plunging them in a warm propagating case. Care should be taken to see that the cuttings are not allowed to flag. This plant may also be successfully propagated by cutting the old stems into short lengths and inserting them as cuttings, and this is an excellent way where difficulty is experienced in rooting the young shoots. Where it is desired to grow on the old plants they should be cut down to within a few inches of the base, and when starting into growth turned out of their pots and the balls of soil reduced so that the plants may be repotted into the same-sized pots. Afterwards pot them on as they require it. In their young stages they should be grown in a temperature of about 60° and afterwards given cooler conditions; in fact, they may be successfully grown in cold frames. During September they should be removed to warmer quarters. They require strict attention at all times as regards watering, and when they have well filled their pots with roots they enjoy liberal feeding. There are white and rose coloured varieties which are worth growing for the sake of variety.

Lantana salvifolia when grown in pots and kept well pinched in its younger stages is very useful for furnishing the stages in the conservatory. If grown on into large pots and the slender shoots allowed more freedom of growth it makes a fine specimen several feet in height. Where it can be planted out it is ideal for clothing pillars, the shoots attaining a length of 10ft. to 12ft., and it produces its flowers in wonderful profusion over a long period. It is easily propagated by means of cuttings at any time, young shoots rooting readily in a close case. This plant is generally known in the trade as L. delicatissima.

Lantana Camara, of which there are many varieties in varying shades of red, orange and yellow, were at one time very popular for the greenhouse, but are seldom seen at the present day. These plants are very useful for greenhouse decoration during late summer and early autumn. They can be raised from seed, but named varieties must be propagated by means of cuttings which root readily during the spring or summer. They are bushy growing plants, and to ensure well furnished plants the young shoots should be pinched several times. Their successful cultivation presents no difficulty, as they grow quite well in an ordinary greenhouse.

Primulas kewensis, verticillata and floribunda are all very useful for greenhouse decoration. Seed should now be sown in a cool pit or greenhouse. These plants all grow freely in any good potting compost, and may be grown in cold frames during the summer months. Plants of P. verticillata raised from seed last year are worth growing on, as they will make very fine specimens for next year. The original P. kewensis is sterile and must be increased by division. It is now scarce in cultivation, the seed-producing variety being more generally known and cultivated.

GENERAL LIBRARY

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2744 Saturday, June 21st, 1924 Price THREEPENCE

The Kelway Colour Border

is planned for continuity of bloom as well as colour effect. Your garden is of enduring beauty from early Spring to late Autumn, and so continues for several years, as a result of the minimum of cultivation, expense and attention.

These Colour Borders have evolved from many years of experience, and clients get the advantage of securing, amongst other subjects, the world-renowned Kelway Specialties in Hardy Plants.

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

We are only too pleased to advise.

WRITE NOW to the inventors of Colour Borders:

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know this Booklet?

If you know it, there is no question at all about it; you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

A CHRONICLE OF EVENTS

THERE is an old—and true—Scotch saying that it is an ill wind that blows nobody any good. This is especially true in gardening this year, for above all this is a season for the tree and shrub gardener. The alpine enthusiast and those who love herbaceous plants may grizzle and grumble, and with reason, at the way their flowers are tashed and damaged by the rain, for in many parts of the country it has been fierce and unrestrained, but all shrubs and trees are growing famously. Most of the ligneous plants in our gardens come from distant lands. Look at any list of them: you may find that 10 per cent. are native products, that a further 15 per cent. are natives of Europe, but the greatest proportion come from China, North America, South America and New Zealand in that order.

It is only natural that trees and shrubs love moisture, for remove the forests and the rainfall diminishes rapidly and *vice versa*. It is well known that many countries which have been denuded of their forests are now suffering from lack of water. They have become barren and their soil is unproductive. The corollary is that most trees and shrubs like water and moisture during their growing season. This they are getting with abundance this year, and they are expanding under that genial influence.

In many parts of the country, particularly on the east coast, there has been a lack of sufficient rain during the growing season for many years, and so plants which may have been in the ground for as long as five years have never become properly established. This is now being rectified. Perhaps a few measurements from a garden in Perthshire may be of interest.

Rhododendron Souliei made a growth last year, a very cold hard growing season, of 1½ins., this year by June 10th 8ins. with the shoots not yet fully grown. Leaves one-third larger. Incidentally, this is one of the very best rhododendron species. It is absolutely hardy and has lovely pink or white open campanulate flowers.

Betula Delavayi made a growth of 8ins. last year; this year half-grown shoots are over 10ins. in length.

Boenninghausenia albiflora is a foot high this year; at the same time last year it was 5ins. This is a plant which some people find difficult to grow. I have had no difficulty with it and it has now begun to spread by underground runners. On no account will it stand stagnation at its roots. It likes a position where drainage is quick; in fact, a dryish bank with some shade is all that is necessary. It dies down every year, and is particularly lovely with its foliage like a maidenhair fern covered with tiny white stars. It is also deliciously aromatic. This season has even suited this comparatively dry-loving plant, but then I have planted it on a bank with a shelf of sloping rock a foot below the surface. This plant should be grown more often, for it is more graceful than most thalictrums.

Lonicera syringantha, always a vigorous grower, has made gigantic strides this year, and is rapidly encroaching on its neighbours; growths three weeks in advance of last year.

Dipelta floribunda, growth 6ins. this year compared to 3ins. last year. This is a young plant, and I find it slow to establish itself in Perthshire.

Rhododendron Fargesii is the most amazing instance in this growing season. They are planted practically in the open, perhaps too much so, but this year the growth is 1ft. compared to 3ins. last season.

And so the chronicle could continue. The only damage that I can see is in some of the small seedlings in the nursery beds in thick shade. Here the drip from the trees overhead has been so heavy and consistent that they have been covered with mud splashed over them by the large drops. Some have been practically smothered with earth and have had to be excavated, while even the largest have a thick coating of mud over the stem and leaves. This is a nuisance, as it interferes with the plant's breathing apparatus, and I look for numerous deaths later on in the year, for mud splashed on in that way is extremely difficult to get rid of. Several of the worst cases I removed and soaked and then syringed with but little effect.

All who are growers of trees and shrubs should be thankful for this magnificent growing season; some people, at any rate, will be satisfied, and I am one of them. E. H. M. C.

Owing to the late season, the Council of the Royal Horticultural Society decided that the first of the three silver cups presented to the Society for peonies by Mrs. Edward Harding will be offered for award on Tuesday, June 24th, for the best exhibit by an amateur of three flowers each of six varieties. The Council hopes that as many amateurs as possible will send in entries. The Society makes no charge for space, and vases are obtainable at the hall.

ENKIANTHUS

BY W. J. BEAN.

THE frequency with which enkianthuses have been shown at recent meetings of the Royal Horticultural Society seems to show that the genus is growing in favour. But the exhibits have almost wholly consisted of E. campanulatus with an occasional appearance of E. japonicus. For general serviceableness there is no doubt that, of the species at present available, E. campanulatus is first, but there are others which, if not perhaps so adaptable to our ordinary conditions, are very charming plants with individual flowers of greater beauty.

Enkianthus belongs to the heath family, and its flowers have the characteristic bell shape or pitcher shape of the group; they are always nodding or pendulous, and the largest are only about ½in. wide, most of them smaller. All the species are deciduous and their leaves vary from ¾in. to 3ins. in length. No inconsiderable part of the attractiveness of these shrubs is in the autumnal beauty of the foliage, which turns red, orange or yellow before falling.

They may be grown wherever rhododendrons succeed, either in a peaty soil or in a lightish, or at least an open, loamy one. I do not think they will succeed where the soil is chalky, but whether peaty or loamy it will be improved by adding leaf-soil. Before planting the shrubs, the ground should be broken up to a depth of at least 2ft., so that, should a dry time ensue, they have a reasonable chance of getting through it unharmed, for they detest dryness at the roots. Like most small-leaved deciduous shrubs, they do not need shade, although where the soil is light or shallow and liable to get dry quickly, a spot where a shadow is cast over them in the hot, middle hours of the day would be advantageous. Propagation is

THE BELL SHAPED BLOSSOMS OF E. CAMPANULATUS.

done by seeds which, as is usual in the heath family, are small. They must be treated like those of rhododendrons or heaths and sown on the surface of well drained pots, pans or boxes of very sandy peaty soil. The seeds will be all the better with a sheet of glass over them to prevent quick evaporation and, in consequence, frequent watering, which should be done by using a very fine rose or by partially immersing the pots. With all extremely small seeds it is essential to avoid moving or "washing" the soil by rough watering, especially when germination has started. Many failures with delicate subjects may be attributed to this cause. Cuttings made of twigs 2ins. to 3ins. long may also be used, putting them in very sandy soil during July or August in a propagating frame where there is some bottom heat.

E. CAMPANULATUS is usually a shrub with us and is already 12ft. high or upwards in some gardens. In its native country, Japan, it is frequently a small tree up to 30ft. high. It has a method of growth characteristic of several enkianthuses and of many Japanese trees and shrubs, and ultimately develops flat, horizontal tiers of branches. The leaves—mostly obovate and 1in. to 2½ins. long, are clustered towards the ends of the twigs and the flower racemes appear there also, the corolla being bell-shaped, ½in. long, pendulous, dullish creamy white veined with red, each of the five lobes tipped with red also. The colour, however, is variable and in one form, albiflorus, is creamy white.

E. PALIBINII, the enkianthus figured as E. campanulatus in the *Botanical Magazine*, t. 7509, is very distinct. I called it E. camp. var. Palibinii in my book on Trees and Shrubs (Vol. 1, page 512), but Professor Craib of Aberdeen University has since given it specific rank as E. Palibinii simply, in which I think he is right. The flowers are rather smaller than in ordinary campanulatus, and almost entirely rich red; the leaves, too, are more coarsely toothed. E. Palibinii used

THE PURE WHITE, PENDULOUS FLOWERS OF E. JAPONICUS.

Digitized by Google

be grown in the Coombe Wood nursery, and is probably grown in some gardens now as campanulatus, under which name it used to be sold. It is very charming and well worth looking after.

E. CERNUUS (syn. E. Meisteria) is a much branched shrub up to 6ft. or 9ft. high in Japan, with obovate leaves ¾in. to 1¼ins. long. The flowers are very distinct from those of other enkianthuses through the corolla, which is bell-shaped and ¼in. long, having its margin divided into numerous slender pointed teeth. In the typical form they are white, but in the variety rubens are of a deep rich red. This coloured variety is a beautiful shrub but very rare, and I do not know any trade firm that stocks it. Efforts to purchase it have hitherto only resulted in adding to one's stock of campanulatus. There is a good example of the true plant at Caerhays.

E. SINO-HIMALAICUS.—Professor Craib distinguishes by this name the plant introduced for Messrs. Veitch by Wilson from western China, which was previously identified with himalaicus (a species from North India and Nepal) and generally grown under that name. Wilson describes it as a large bush or small tree often over 20ft. high. The leaves are narrowly oval or lance-shaped, tapered at both ends, 1in. to 3ins. long and more or less hairy, especially beneath. The flowers, widely bell-shaped and about ½in. wide, vary in colour from salmon-red to orange and yellow, with veins of dark red. The foliage turns golden to crimson in autumn. This species, which is thriving well in cultivation, is described by Wilson as one of the most beautiful shrubs of western Szechuen. The true North Indian himalaicus is said by Professor Craib to be hardy at Edinburgh and to have been grown in the open air there for twenty years.

E. JAPONICUS (syn. E. perulatus).—In Japan this is usually a bush from 3ft. to 6ft. high with horizontal tiers of twiggy branches and narrowly obovate leaves clustered at the end of the shoot, each from 1in. to 1½ins. long. The flowers are pure white. pendulous, pitcher-shaped, about ¼in. long, produced in clusters of two or three or more, each on a slender stalk. The corolla has five rounded protuberances at the base. The foliage turns to golden yellow in autumn. Introduced by Standish about 1869, it is still too rarely seen, although it comes next to campanulatus in popularity.

E. SUBSESSILIS (also called E. nikoensis) is more nearly related to japonicus than any other we cultivate and has white flowers of a similar pitcher shape, but produced on drooping racemes, each of six to twelve flowers, instead of the stalkless clusters of E. japonicus; nor has the corolla the five swellings so characteristic of that species. They open in late May and are only one-fifth of an inch long. The species is, in fact, one of the least ornamental in bloom. It has, however, all the autumnal brilliancy of the genus, the leaves changing then to bright red. It is said to be a bush up to 9ft. high in Japan.

E. CHINENSIS, found by Wilson in western Hupeh, is, judging by dried specimens, a very handsome shrub, not surpassed in beauty by any other enkianthus. It is sometimes 20ft. high and has large widely bell-shaped flowers described as "salmon, salmon-red or yellowish orange striped with red." Wilson sent seeds to the Coombe Wood nursery and it may be in cultivation, but I have never seen a living plant.

E. QUINQUEFLORUS is a tender species from Hong Kong and south China which may, nevertheless, be hardy in Cornwall as it was for many years grown in the Temperate House at Kew. The flowers are two-fifths of an inch long, pink or peach-coloured, the leaves 3ins. or 4ins. long.

Of rarer species in cultivation there is E. sulcatus, one of Wilson's introductions from China; also ferrugineus, latiflorus, pallidiflorus, pendulus, recurvus and tectus, all from Japan and first described by Professor Craib in "Notes from the Royal Botanic Garden, Edinburgh," October, 1919, and said by him to be in cultivation there at that time. The last six from Japan appear to be more or less closely related to campanulatus and may possibly be in cultivation elsewhere under that name.

ANOTHER CATALOGUE

BY THE HON. VICARY GIBBS.

I WAS much interested to read in your issue of May 24th a laudatory account of the catalogue of my friend, Mr. Clarence Elliott, relating to herbaceous plants, and it tempts me to give an account of another which commends itself to me and relates more particularly to woody plants. I will not disclose the name or address of the issuer for fear that the just and stern editor of THE GARDEN might feel compelled to attach the ominous contraction "Advt." to the end of this paper, and instead of sending me a handsome cheque in return for my remarks, demand one from me. With all that is said by E. H. M. C. as to what is required to constitute a good and useful catalogue I heartily agree. Of course, if the reader were like Solomon and knew all plants from "the hyssop on the wall to the cedar which is in Lebanon," he would need no descriptive matter, but such a man would probably have a well stocked garden of his own, and is not the kind of person for whom, primarily, a nurseryman would have to cater. It is the man who has recently acquired a garden and desires to beautify it, who is the best customer and ought to be studied.

What is a man like that to make of a long Græco-Latin name such as Hydrocephalus Kamtschatika, and is he likely to order it, if he has no idea whether it will prove to be a hardy forest tree or a tender bog plant. On the other hand, if the name be followed by an appetising account, such as "shrub, 2ft. high, rich carmine flowers end of May, followed by large sapphire blue fruits in September," he will, if he believes the story, be sorely tempted to send the sum demanded and secure the treasure. I am very far from being a beginner, for it is now, alas! well over fifty years since I was first keenly interested in plant life, but I can sympathise with beginners, and remember how I used to pore over catalogues, and sometimes order plants without the wildest idea of what the name represented or whether there was any chance of it thriving at Aldenham. Those past days were very different from the present. I had to plough a lonely furrow, people interested in gardening beyond lobelias, geraniums and calceolarias for the outside borders, and stove plants and camelias for the conservatory, were few and far between.

Trees and shrubs were quite outside the sphere of a professional gardener, and he was inclined to regard them as mere background and not as subjects of individual interest. Of course, the fact that printing has increased so greatly in cost since the war, tends to make anyone who is selling plants for his livelihood stingy about spending money on descriptions; but they need not be long, and without them I am quite sure that it is impossible to create a free market. If one has in stock many species of one genus which are perhaps little known in this country, there is a temptation to block them altogether in some sentence like this: "American Cratægus in great variety, names and sizes and prices on application," but the result is likely to be disappointing. If, instead, half a dozen are named and attractively described, thus:

Cratægus macracantha, a free grower with great thorns 5ins. long, like curved skewers.
Do. mollicula, fine deep yellow fruits, like miniature oranges.
Do., crimson fruit, award of merit from R.H.S.

the result as far as orders are concerned is likely to be much more satisfactory. Here is a sentence in the catalogue on which I am commenting which has my warm approval. "All plants unless otherwise specified are on their own roots." As a rule, nurserymen are far too prone to stock grafted plants of genera where such a process is quite unnecessary; it is only gardeners of experience who realise how inferior are grafted plants. Many of my old plants, which I obtained

Digitized by Google

before I knew better, even of subjects like cratægus, which practically never hybridise and come quite true from seed, are grafted, and every year are disfigured by growth from the stock (white thorn) below the graft, which has laboriously to be removed, only to reappear next season. Again, almost the whole of the English nursery stock of lilacs is grafted, and if these are neglected for a few years it will be found in many cases that the stock has smothered the scion. Of course, I freely admit that in the case of apples, whether ornamental crab or of orchard type grown for fruit, it is quite impossible to raise any true from seed, and therefore, if choice forms are to be obtained they must be grafted, but I most strongly urge that the practice should only be resorted to when necessity compels.

Of course, as E. H. M. C. observes, catalogues ought to be truthful, though allowance must generally be made for that failing in human nature which tends to convert every man's own geese into swans. One of the most difficult things to decide is what constitutes hardiness. There is nothing absolute about it and any statement that a plant is hardy must be taken to mean hardy in the nursery from which it comes; the plant quite hardy in Ireland, Wales and Cornwall is impossibly tender in Cheshire, Northants and Herts. Nor is this all, for I never inspect any large collection of trees and shrubs without finding strange anomalies: a plant usually regarded as tender which has grown and flourished for years, while one which the books would tell you was much more robust has been half killed or succumbed altogether. The explanation is that where a plant has a soil which exactly suits it, its natural vigour will enable it to resist an inclement climate. Whenever we have a severe winter it is, as one would naturally expect, the feeble and sickly specimens which are wiped out altogether; nor is this to be regretted, for the commonest tree or shrub in full health is a more beautiful object than the choicest example when struggling to maintain life.

Here is another sentence in the catalogue under review which can claim praise for its frankness: "The plants offered are seedlings raised from the type plant and are not guaranteed strictly true to name." This note is attached to a long list of different berberises, for that genus, when leaving its native habitat in China and settling in England, has, I regret to say, lost all sense of morality and hybridises recklessly, with the result that seed collected in an English garden produces all kinds of variants, some of which, such as those which Wisley has exhibited, surpass the type in ornamental value. On another page of the same catalogue I find Cratægus Oxyacantha Gireoudi offered, and there is a botanical curiosity about this thorn which is worth recording, as it may be new to some readers. "The young growth is mottled with white and pink giving the tree the appearance of being covered with flower," says the catalogue, and so far as I know this is the only variegated shrub or tree of which the seed can be depended upon to reproduce the peculiar colouring of the parent. It was the blackbirds or thrushes which first called my attention to this, for when feasting they dropped some of the hips and haws in adjoining shrubberies, where they grew and their showy colour attracted my attention. I then sowed and raised about fifty plants, every one of which was as fully variegated as the parent. Since variegation proceeds from insufficient chlorophyl, it is strange that this feature should be reproduced in the offspring, and still more strange that it should be confined, so far as I am aware, to this one species.

To return to the catalogue, perhaps the descriptions lack the "snap" and spirit which Mr. Elliott's individuality puts into his accounts, but at any rate they give the ignorant beginner some idea of what kind of thing he is buying, as will be seen if I follow E. H. M. C.'s example and give a few instances taken at random:

Hymenanthera crassifolia.—Native of New Zealand, semi-evergreen, related to the pansy. Carries a plentiful supply of pearl white berries in autumn. A compact shrub for rockeries.

Lonicera Maackii.—One of the most beautiful of bush-honeysuckles. Flowers pure white, turning yellow, followed by red fruits. A very strong grower.

Muehlenbeckia complexa.—A curious and interesting trailing species with many interlacing wiry twigs, excellent for covering old tree stumps.

Photinia villosa.—Good deciduous Asiatic shrub, with foliage turning a fine bright red in autumn. Flowers white, fruit red.

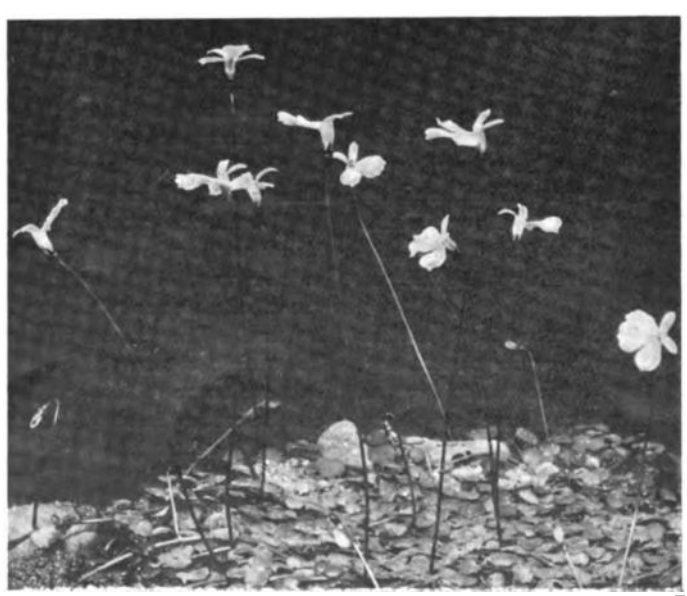
Pyrus malus aldenhamensis (Grafted plant).—The best crab yet introduced; foliage, flowers, fruit and wood all red-tinged in a greater or lesser degree. A.M.R.H.S.

I am afraid that this catalogue is no richer in cultural directions than Mr. Elliott's, no doubt they would add to its usefulness, but the cost of printing is too heavy for such luxuries.

A FEW RARE CREEPING PLANTS

BY H. CORREVON.

THE "Clover of the Gods" (Parochetus communis), is an exquisite little plant, whether creeping over the soil or hanging from walls or baskets, when used as a hanging plant. It slightly resembles a pea, with long rooting stems, bearing pretty trifoliate leaves slightly spotted with brown, and from the mass of the leafy carpet emerges all through the summer and far on into the autumn, crop after crop of big pea-shaped flowers, each borne singly on its separate stem (2ins. to 3ins), in colour a bright azure blue, similar to that of Gentiana bavarica. It is that metallish blue, most exquisite of all, tinged with opal, marine, cobalt, sapphire, turquoise, etc. It flourishes at Floraire in a semi-shady bed of leaf-mould mixed with loam, and flowers from May till winter. Outside we have to cover it up for the winter, but in November we usually move some into bays in a cool greenhouse, where they flower the whole winter through. This beautiful plant comes from the Himalayas and East Indies.



LOBELIA LINNÆOIDES.

HEERIA ELEGANS is a delicate creeping plant sent to our gardens from the mountains of Mexico. I saw it once in the Royal Botanic Garden at Edinburgh and carried it home with great care, as, to my mind, no other flower offers such a

Digitized by Google

beautiful colour. It cannot be said to be quite hardy and must either be covered or brought into frames for the winter. The whole summer through it produces a carpet of brilliant magenta flowers, suggesting those of Epilobium obcordatum, although rather flatter. It wants peat or leaf-mould to be really successful, and it belongs to the Melastomad family.

EPILOBIUM LATIFOLIUM is the most beautiful of all the epilobiums. Coming from the arctic regions of Greenland it is generally very difficult to grow at Floraire, but we planted it in 1897 in our alpine botanic garden at 4,800ft., in a rockery facing north-east, and there it has grown and flourished. The foliage is bluish and broad, and the flowers are very large and of a light carmine rose. It is rather a terror if the ground proves suitable.

FALKIA REPENS is a small creeping and half-shrubby plant, with evergreen shining leaves; it is a beautiful little plant, coming to us from the mountains of South Africa. I saw it in 1904 in the Botanic Garden at Leipsic, where it was considered to be a great rarity. They gave me a little piece of it and we planted it here, where it flowers during the whole summer with little convolvulus-like light rose cups. It must be covered in winter or brought into a cold frame.

DICHONDRA REPENS is another relation of the convolvulus which I saw at the Botanic Garden at Turin. It is a very dwarf creeper, running all over the place, bearing kidney-shaped, light green, round leaves, and small yellowish axillary flowers. It is a sub-tropical plant which has proved hardy or half-hardy here and is good for light soils in half-shady and sheltered situations.

GOODENIA or SELLIERA REPENS, from Tasmania, is a little creeping lobelia-like plant for the rockery, where it runs along, with narrow foliage and solitary short-spurred white flowers, slightly bluish at the tips. It is hardy here as well as at the Botanic Garden at Turin, but it requires a sheltered position.

SAXIFRAGA CUSCUTÆFORMIS, from Japan, is a diminutive of S. sarmentosa, very sarmentose, with pretty leaves and bearing innumerable slightly pink flowers. It is not easy to keep and seems to be much more delicate than its relative. There are two other varieties of the "Mother of Thousands" which we once grew here, but have since lost; one was the form with variegated leaves (pink, white and green), of the type which is very difficult to keep in our climate, even under glass. The other is called S. japonica, *Hort.*, which I got some forty years ago from M. Boissier at Valleyres; it has thicker leaves than sarmentosa, dark brown underneath, only slightly variegated over the surface and is less sarmentose. Can any of your readers give me any information about it?

LOBELIA LINNÆOIDES is a little gem from New Zealand; it has leaves like a Linnæa borealis, is of a very prostrate nature and bears charming white butterfly flowers slightly tinged with blue. Alas! It has also disappeared. What must I do to keep that beautiful thing alive?

MIMULUS PRIMULOIDES is another little gem from New Zealand, which covers a part of our "tourbière" here. It is a low creeper, with small rosettes of hairy pendulous foliage and bears lovely yellow flowers the whole summer long. In the autumn one must be careful with the small bulbils which, just like those of pinguiculas, contain the nutriment required for next year's start. It likes a damp place.

SAXIFRAGA CUSCUTÆFORMIS.

MIMULUS PRIMULOIDES.

VERONICA CANESCENS, from New Zealand, is the most minute and dwarf thing I know of in plant life. It has microscopic, hairy leaves and runs flat across the surface of the ground. In summer the tiny carpet is covered with sweet little china blue flowers. It must have a dry and sunny exposed situation.

VERONICA TELEPHIFOLIA, from the Caucasian and Asia Minor mountains, makes flat sheets of tiny rosettes, built of minute rounded leaves of the most lovely glaucous shades of green. In the summer the tuffets are covered with azure blue flowers. The plant must be covered, in this garden at least, but resists the severe winters of the high garden on the Alps because there it is covered with snow. The same observation can be made of many of the plants I have named in this article, and with others like the yellow New Zealand Myosotis australis and M. Traversii, Epilobiums linnæoides, glabellum, macropus, and others. Many plants which are tender here in our winters destitute of snow will be perfectly happy in one of our alpine gardens which is snow-coveerd the winter through.

[The photographs were supplied by Mr. R. M. Adam, Royal Botanic Gardens, Edinburgh.—ED.]

SIMPLE GARDENING

EARTHING-UP POTATOES.

ALL the early and most of the second early varieties will be earthed-up and filling the space between the rows with luxuriant haulm. But many maincrop sorts will need attention now. It is always advisable to pay close attention to the proper carrying out of this work in dealing with all varieties, but it is most important in the case of late ones. There are several reasons for the earthing of potatoes: to add support to the haulm, to ensure a fairly dry medium for the tubers when they are maturing in a naturally moist soil, to increase the temperature of the soil and so hasten the swelling of the tubers and to lessen the virulence of the disease if it comes.

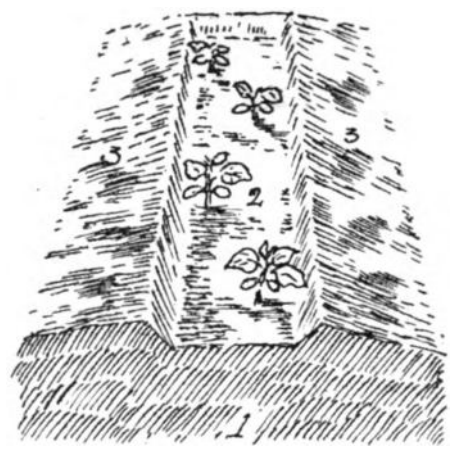
In a naturally heavy soil the ridge should be sharp to prevent rain washing down to the tubers too freely. In a sandy or a light loam the top of the ridge should be left about 5ins. wide to ensure the retention of a good percentage of rain-water. In wet spells, such as we have experienced lately, the runners permeate the moist soil freely in all directions, and if earthing-up is delayed unduly many young tubers will be destroyed when the soil is disturbed. If the soil is drawn up in good time the runners permeate the soil where there is most moisture—in the centre of the ridge—and as they are not again disturbed there is no check to growth and so the crop matures for lifting in good time.

RAISING BIENNIALS.

The main kinds that I wish to refer to here are wallflowers, polyanthuses, primroses, sweet williams, Canterbury bells and giant-flowered daisies. The very best results follow when the young plants are raised early—in June—and allowed to grow sturdily in the open border. It may be convenient finally to transplant the resultant plants in the autumn; if so, they will be strong for the purpose and pass through the winter without serious checks. If they are not finally planted in the autumn a nursery bed will be their proper place throughout the winter months. The seedlings of all these biennials may be raised in the open border now. If the border soil is stiff and not very suitable for sowing seeds in the cultivator should procure a barrowload of finer loam and of a lighter nature. This should be evenly mixed with the border soil and shallow drills opened 6ins. apart and 2ins. wide for the reception of the seeds. The latter should be sown very thinly and covered lightly, as nearly all the seeds are very small. Then the cultivator should decide as to the desirability of finally transplanting in the autumn or the following spring. In both cases it will be necessary to transplant the seedlings twice prior to the final planting. The first time at 3ins. apart and the second time at 5ins. It means a little more trouble, but the resultant plants will be bushy and sturdy

VEGETABLE MARROWS.

Usually the preparatory work for growing these plants is too elaborate. The high, dry bed is not required. Plants grown on a heap of garden refuse—decaying weeds, used potting soils and those from boxes, mixed, perhaps, with some tree leaves and, maybe, rotting manure—do remarkably well. This is simply because the plants have something substantial to root in. The high, dry bed is a failure because the thin crust of soil is not sufficient for the maintenance of the roots; the latter may enter the litter, but perish in it when the whole mass dries up, as it generally does in July just when the first embryo fruits are in flower. Through this unnatural overdryness of the soil several inches below the surface—a condition unsuspected by the cultivator—the fruits (marrows) fail to set and swell. All cultivators are not able to command a good heap of garden soil and decaying rubbish, nor its better substitute, a heap of rich



soil and rotted manure, but the majority may grow the plants as shown in the sketch. A ridge of soil 4ft. wide is made up; the centre, No. 1, is hollowed, plants are put out as shown at No. 2, with sheltering ridges, Nos. 3, 3. Some good soil and rotted manure being mixed with the soil in the hollowed portion, the plants soon grow and cover the whole heap, and the hollowed portion ensures easy watering and feeding.

HARDY CLIMBERS

These are very beautiful when properly planted and trained during their season of growth. It is an easy matter to mar the beauty of the plants at this season of the year, either by bad training and or ill-conceived pruning. It is not generally known that Clematis Jackmani makes new shoots 5ft. long before the flower-bud forms and 5ft. of young growth after that bud has developed. When this characteristic is realised it is easier so to train a plant on a wall or fence that the flowers will be evenly disposed practically all over the space and not at the top only.

That charming, effective pillar and pergola climber Muehlenbeckia complexa should be trained now so that the long, graceful shoots depend in a natural way. The beauty of the plant is spoiled if the masses of delicately grown shoots are tied up stiffly and formally. The dying and dead wood can now be clearly seen in the climbing roses and also in other kinds of climbers, and all such should be cut out at once, also weakly young shoots and stubby portions of older branches. These attentions at this season result in better formed specimens and prevent overcrowding, the latter being an evil that interferes with the due ripening of the wood retained for next year's display of blossom.

The old wood should be cut out altogether and neatly; the young, useless shoots, too, but the moderately strong branches that may be dispensed with should be cut back to within 6ins. of the base so that new shoots will take their place.

ALPINE AND HERBACEOUS PLANTS.

It is scarcely possible to deal with the raising of the more tender kinds from seeds in detail and in a short note, as really some practical knowledge of the work should be possessed by the cultivator. To sow seeds of the more tender kinds in the open ground would be an act to court failure. A cold frame or a low pit structure would answer the purpose of seedling raising and the propagation of cuttings. It is always best to sow the seeds of biennials and perennials directly they are harvested. The seeds of a thin paper-like appearance, similar to those of the parsnip, generally lose much vitality if they are kept until another year. By sowing in well drained pots, pans or boxes, or even in a bed in a frame, there is an opportunity of watching the development of practically every seedling, as these tiny specimens—especially those of the alpines—are soon destroyed by slugs, woodlice, ants and other pests. In the frame or the low pit there should be no difficulty in shading and ventilating exactly to suit the requirements of the young seedlings. The seed and seedling receptacles of the minute-growing kinds should be gently immersed and as gently withdrawn when water is needed. Surface applications of water to such tiny plants would do more harm than good. As the seeds of some kinds require a long season in which to germinate, the cultivator should become acquainted with them, at least as to kind and variety, and so have patience. GEORGE GARNER.

FORTHCOMING EVENTS.

June 24.—Royal Horticultural Society's Fortnightly Meeting (two days). Lecture on the first day, at 4 p.m., by Mr. W. J. Dowson, M.A., on "Gardening in the Highlands of Kenya Colony."

June 25.—Morley Paxton Society's Meet.

June 26.—Royal Botanic Society's Meet.

EARLY SUMMER IN THE PYRENEES

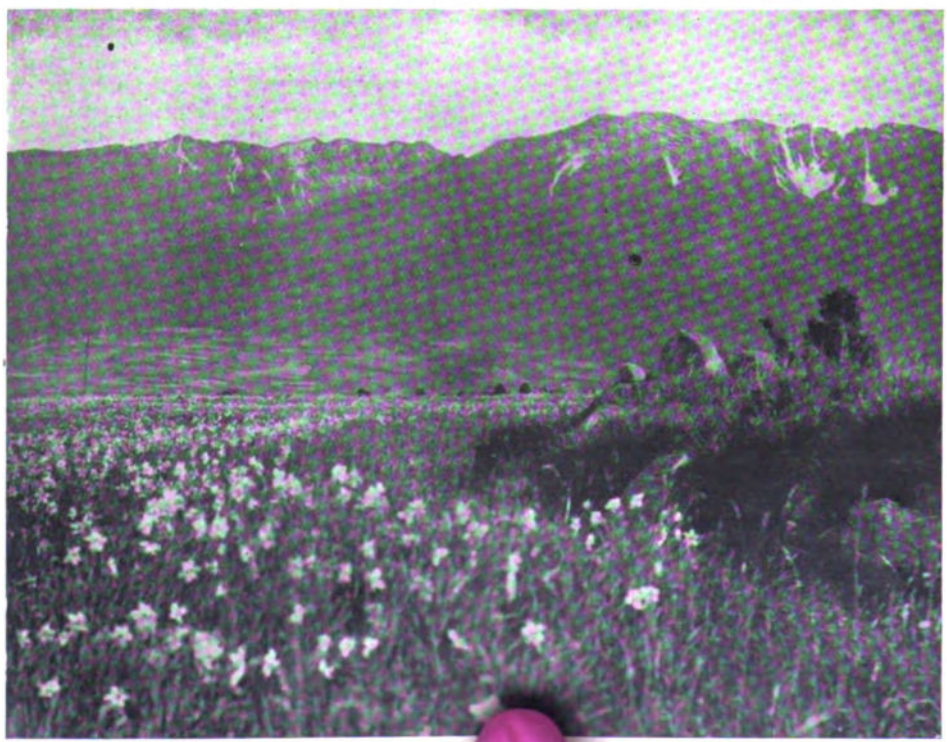
SO MANY PEOPLE HAVE BEEN ACCUSTOMED TO VISIT SWITZERLAND IN PURSUIT OF PLANTS, AND HAVE FOUND IT OVERCROWDED, THAT THIS ARTICLE MAY SUGGEST ANOTHER MOUNTAINOUS CORNER OF EUROPE FOR A HOLIDAY.

IT is odd how few English people know the French Pyrenees; know them, I mean, as they know the Alps. They may admire them from Pau or go for excursions into them from St. Jean de Luz; but we did more wisely, I think, in approaching their heights from the east, coming in from Perpignon through the beautiful plantations of almonds and vineyards on their lower slopes. We wanted to reach the higher places where we might hope to find those flowers which have pyrenaica as their second name. So we passed Vernet-les-Bains and did not leave the little train till it had wound its curly way up the gorge and emerged, breathless, but triumphant, on the open plateau where stands the highest fortified town of France — little Mont Louis No straggling allowed here! No residential streets wandering into the meadows or vaguely up the hill-sides! All is neatly and tightly packed within the compass of its solid walls and moat, and only one gateway at which to enter! We had a choice of two inns at which to stay—or thought we had until we discovered that one of them was not yet open in the middle of June! Both are very simple, neither have any view—the fortifications see to that. But our little Hôtel de France was clean, and it was pleasant while eating dinner to discuss its merits—which were considerable—with the cook, who wandered into the dining-room for a chat.

THE HIGHEST FORTIFIED TOWN OF FRANCE—MONT LOUIS.

Mont Louis was cold in the middle of June; the meadows were white with narcissi — what optimists they are! But one morning we woke to find them even whiter with a heavy fall of snow, which made the kindly inhabitants sorry for our sake, but evidently did not surprise them. What will you? If you want to see the crowd of spring beauties—the yellow globe flowers and forget-me-nots, the purple orchises and the violas making a Botticelli pattern in the tender grass, you must not grudge Old Winter having a last peep at them too.

The snow did not lie; the narcissi — or most of them—shook the weight of moisture from their petals and stood up bravely in the sunshine, while the smaller darlings, the butter-worts, the many gentians—including pyrenaica—and the saxifrages, sparkled and laughed at the edge of the rushing, swollen rivulets. One could stay long at Mont Louis; there is no climbing, but many and lovely are the walks, not only among open pastures, but through deep woods where, if searched for carefully, the sweet scented Pyrola uniflora may be found.



THE MEADOWS OF MONT L[illegible]TE WITH NARCISSI.

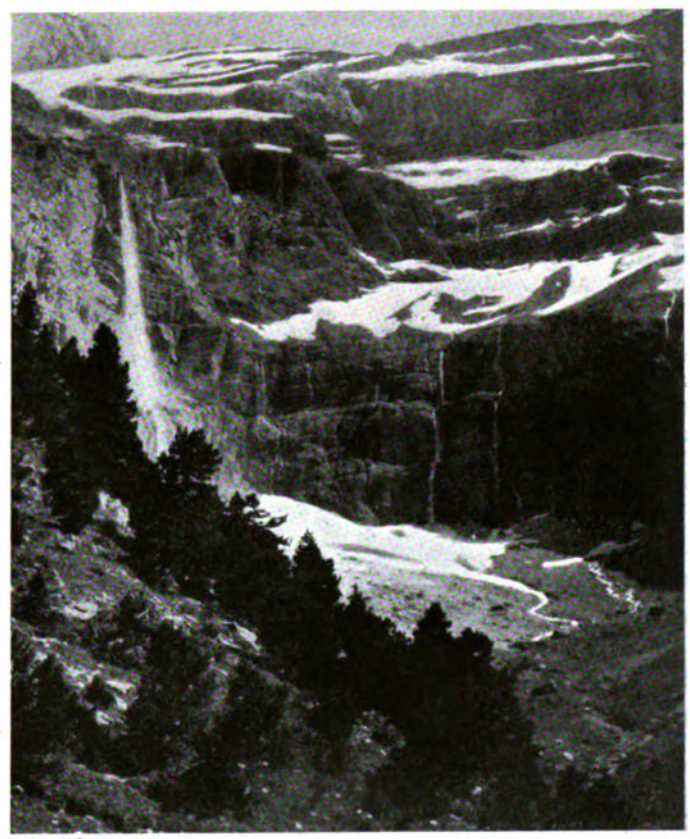
When we left, it was to go by train and car, driving slowly and with many pauses, to Bagnères de Luchon, via Foix. So long as one does not cross the frontier into Spain, the roads in the Pyrenees are as good as those elsewhere in France, but we were glad to have a local driver who knew the peculiarities of the hairpin corners! On our way to Foix we were shown the road leading to Andorra, but our desire to penetrate among its wild-looking hills was damped by hearing of the lack of roads and inns and the general discomfort of travelling therein. At Luchon we seemed to have returned to civilisation! A casino, even before it was opened for the season, and a large établissement for drinking and bathing suggested the crowd one would find there later, and it must be a very

Digitized by Google

hot little place, tucked down between its steep wooded hills. But if you mount those hills you are again on the high rolling spaces of the uplands. We spent many pleasant days at Superbagnères gathering daffodils, big-flowered ranunculus and dog's-tooth violets on its grassy slopes and ridges, and looking at winding rivers far below. One of these rivers we pursued on another lovely day, up the valley of the Lac d'Oo, where the white Paradisia Liliastrum was thick in the hay fields! At the end of an hour's hot scramble up a stony path we were rewarded with the rugged beauty of the Lac d'Oo itself, high up among bare rocks and frowning peaks from whence thunders a mighty waterfall.

To motor from Luchon to Lourdes—our next stopping place—means a long day of most varied scenery and equally varied flora: after the hay fields come the woods, first the oak and chestnut, then the beech and fir, becoming more gnarled as one approaches the summit of the pass, till finally they cease altogether, and low-growing genistas and the beautiful sulphur anemone and alpenrosen are left in the sharp cold air which has so lately been laden with ice and snow. Two

THE VALLEY OF LAC D'OO.



A SECTION OF THE GREAT CIRQUE DE GAVARNIE.

such passes must be crossed and just over the edge of the first one, the Col de Peyresourde, we came on a sight of unexpected beauty: a fragment of the blue sky lying round the source of a tiny spring and outlining its course as it hurries to become an imposing river in the valley below! If the vision, on closer inspection, prove to be formed by a mass of Viola cornuta and flax it is not less surprisingly beautiful on that account; and how wonderful to walk knee deep in the blue of the sky and to gather it in your hands!

At Lourdes we merely paused on our way up again into the heart of the mountains, not this time over high passes and down on the other side, but up by train and farther up by motor and still higher by mule or on foot till the Cirque de Gavarnie blocks the way, and the highest hotel in the Pyrenees discloses its modest existence behind a rocky shoulder. Not an imposing edifice, just a little inn—at which we were the only guests—looking lovely and rather lost in its magnificent surroundings. How could any work of man look otherwise? The great amphitheatre of precipice rising to a height of 1,500ft. from its rocky floor and showing no foothold for even the most adventurous climber to ascend; rose pink and purple when the setting sun sends the shadows creeping up its face; incredibly cold and remote when the moon turns its naked rocks to steel and its snow ridges to silver; awe inspiring always, in whatever mood, and a barrier complete and impenetrable. To explore this Cirque de Gavarnie one must be a good walker; tourists usually stay at Gavarnie itself, some miles down the valley, and content themselves with coming up on mules to gaze at the Cirque while they drink a cup of indifferent coffee on the terrace of our little inn, so that no paths or resting places are arranged for them, and one must scramble and trudge in rope-soled shoes to find the lovely valleys lying to right and left of the main one, and to see the flora of this most interesting district. It is the only place in the French Pyrenees at which we stayed where the higher alpines seem thoroughly at home, or at any rate, where we could get at them. Unlike Switzerland there is no winter sport season to be considered, so there are no really high hotels; but round the Cirque de Gavarnie you may find the delicious pink stars of Silene acaulis, the white dryas, soldanellas, the sweetly scented Erinus alpinus and you may see, with a gasp of delight, the purple sprays of Ramondia pyrenaica hanging from every crack in the shady side of the great rocks. While on the floor of the Cirque itself, with foliage nearly as grey as its surroundings, perhaps the most attractive thing is Geranium cinereum with its large pink flowers so beautifully veined with purple.

It is wise to be interested in little things at Gavarnie—to peer among the rocks for the treasures one hopes to find, to spend a day now and then in some high grassy cup among the hills with a shepherd and his herd of creamy cattle for company, or to work up a real interest in the matrimonial affairs of the innkeeper's daughter! Will she, or will she not, be kind to the mule boy who brings the daily consignment of tourists up the valley. The Cirque itself is so overpowering—in some moods almost unbearably so—that it is a relief to escape its spell. But when you are far away—when you have turned your back on the mountains, and life is a question of hot pavements or dusty hawthorn hedges, any mention of the Pyrenees will conjure up a picture of a great semi-circle of snow-crowned precipices, and will bring to the ears the deep note of many waterfalls.

R. LANDALE.

IRISES AT VINCENT SQUARE

IT was undoubtedly iris time at Vincent Square on Wednesday and Thursday, June 11th and 12th, as irises were exceptionally well shown by many firms. Messrs. Barr and Sons exhibited a very large collection, and included such well known sorts as Lord of June, Alcazar, Ambassadeur, Ed. Michel, Prosper Laugier and Ulysses.

Mr. G. G. Whitelegg exhibited many fine seedlings and such well known sorts as Alcazar, Oriflame, Prosper Laugier, Rhein Nixe and Empress of India.

Such sorts as Shalimar, Lord of June, Alcazar, Shekinah and Crusader were exhibited by Messrs. Lowe and Gibson.

Among the collection from the Orpington Nurseries were Lulworth, Iris King, Shekinah, Ambassadeur and Corida.

Messrs. R. W. Wallace and Co. had a group of irises on the floor near one of the annexes. Here were many seedlings and such sorts as Fro, Lent A. Williamson and Isoline.

On the exhibit by Messrs. Bunyard and Co. we noted Ambassadeur, Eldorado, Mrs. Neubronner and Rhein Nixe.

In Messrs. Waterer, Sons and Crisp's exhibit Lord of June, Neptune, Magnifica, Prospero and Ambassadeur were conspicuous.

From Enfield Messrs. Amos Perry sent many beautiful seedlings, among which the following were notable: Chryrogona No. 1, deep blue purple, lighter falls with silver markings; Dougbract, sulphur cream with brown violet veins; Watsenan, lilac with silver markings; Bulleygraphes, dark purple, yellow markings on the falls. They also staged many well known sorts, among which Banbo and Silver Queen were conspicuous.

In the centre of the hall Messrs. Sutton and Sons arranged a large circular group of their excellent hybrid long-spurred aquilegias.

Mr. Geo. Downer showed some magnificent spikes of his hybrid lupins.

Messrs. Harkness and Son also showed their polyphyllus hybrids. There were some very fine shades to be seen in these two exhibits.

Messrs. Blackmore and Langdon showed some fine delphiniums, including the beautiful variety Sir Douglas Haig. Other notable sorts were Blue Queen, The Alake, Lamartine and Lavanda. This firm also exhibited lupins, pyrethrums and long-spurred columbines.

Perpetual-flowering carnations and Dianthus Allwoodii were shown by Messrs. Allwood Brothers. Among the Allwoodii were many new sorts.

Mr. Engelmann also showed carnations, including such popular sorts as White Wonder, Saffron and Tarzan.

Messrs. Stuart Low and Co. also showed carnations. Here were such sorts as Topsy; Mrs. T. Ives, salmon, good for bedding; and Duchess of York, salmon, shaded carmine. This firm also exhibited their new rose, Roselandia, the quaint Nertera depressa, Bougainvillea Mrs. Butt, blue hydrangeas, Dipladenia amabilis, and Erica ventricosa with yellow tubes, E. Cavendishii and E. magnifica, pink.

Messrs. R. Bath and Co. showed irises, including Lord of June and Rembrandt, geums, pyrethrums and poppies.

Messrs. Ireland and Hitchcock showed Mascott's dianthus. This plant is a cross between sweet william Scarlet Beauty and a single scarlet carnation. The flowers are large, salmon-pink in colour and possess the scent of a carnation.

Mr. Jones again showed many fine plants of hydrangeas. Here were such sorts as Helga, with large flowers of a good rose colour; Maréchal Foch, blue, flushed rose; Parsifal, rose flowers with fimbriated petals.

Mr. F. G. Wood showed rock plants, including the brilliant scarlet Verbena chamædryfolia, Campanula glomerata dahurica, purple; and C. Bellardi, pale blue.

The only exhibit of sweet peas was staged by Messrs. Robert Bolton and Son. Two outstanding sorts were Wembley, soft bluish lavender, and Daffodil.

Messrs. Kelway and Son showed pyrethrums, among which the following were

IRIS SOUVENIR DE MME. GAUDICHAU.

THE TENERIFFE BROOM, CYTISUS SUPRANUBIUS.

Digitized by Google

conspicuous: James Kelway, scarlet crimson; Lady Astor, white; and Mrs. James Kelway, pink.

Messrs. J. Cheal and Sons showed dahlias, including their famous Star varieties. White Star and Crimson Star were two notable sorts.

Messrs. Waterer, Sons and Crisp had a small group of rhododendrons under the clock. Here were two standards of Gomer Waterer and plants of Joseph Whitworth, plum purple. They also showed Kalmia latifolia.

Captain B. H. B. Symons-Jeune exhibited a small rockery on which the beautiful spikes of Saxifraga Tumbling Waters hung. He also showed forms of the small Viola lutea and Tulipa australis.

Messrs. Harkness exhibited their fine strain of Lupinus polyphyllus. Many beautiful shades were to be seen.

Rock plants were shown by Messrs. Maxwell and Beale. The most outstanding were Aster alpinus, Campanula Steveni nana and Primula sikkimensis.

Mr. Wells, jun., showed lupins, pyrethrums and poppies.

Rhododendrons and rock plants were exhibited by Mr. G. Reuthe.

Roses were staged by Mr. Geo. Prince and the Rev. J. H. Pemberton. Mr. Prince showed good blooms of Irish Elegance, Isobel, Allen Chandler and Irish Fireflame.

Peonies albiflora grandiflora and albiflora carnea were exhibited by Mr. F. Gifford.

Irises, lupins, pyrethrums, poppies and Verbena chamædryfolia were shown by Messrs. M. Prichard and Sons.

Poppies, primulas, irises and alpine plants were shown by Messrs. B. Ladhams.

A fine lot of lupins was staged by Mr. H. Marehan.

Pyrethrums, poppies, irises and peonies were shown by Messrs. Rich and Co.

A small ground exhibit just inside the door of Kalanchoe flamea and greenhouse foliage plants came from Mr. E. Watson.

Messrs. Gavin Jones and Ingwersen showed alpines.

Perpetual-flowering carnations, including several seedlings, were shown by Colonel Sir Courtenay Warne, C.B.

Delphiniums and aquilegias were shown by Messrs. Vigers.

The well known St. Brigid anemones were exhibited by Messrs. Reamsbottom and Co.

The New Zealand Fruit Growers' Federation, Limited, sent from Wembley many dishes of apples. The fruits were sound and exceptionally well coloured.

NEW AND RARE PLANTS.

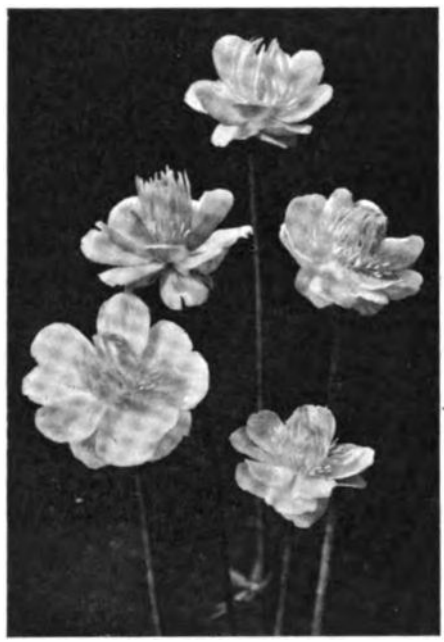
CISTUS ALBIDUS (WHITE VARIETY).—A white-flowered form of C. albidus. Award of merit. Shown by Mr. B. E. Warbury.

CYTISUS SUPRANUBIUS. — Flowering sprays of this beautiful shrub, commonly known as the Teneriffe broom, were shown. The flowers are milky white, tinged rose, and are fragrant. This shrub is native of the Canaries, and it is doubtful whether it is hardy enough to stand outdoors except in the mild parts of the country. Award of merit. Shown by Messrs. R. Veitch and Son of Exeter.

HEUCHERA ARGUS.—The pale rosy crimson flowers are very effective. Award of merit. Shown by Messrs. M. Prichard.

HYDRANGEA ELMAR.—A very well grown plant bearing innumerable trusses of blooms was shown. It is a difficult plant to describe as regards colour; brilliant rose is perhaps as near as one can get. Award of merit. Shown by Mr. H. J. Jones.

IRIS AMBER.—The name is not, in our opinion, exactly apposite. The



TROLLIUS LEDEBOURII "GOLDEN QUEEN."

flowers are clear yellow lightly streaked on the falls, orange beard. Award of merit. Shown by Mr. W. R. Dykes.

IRIS CHRYSOGRAPHES EPAULETTE.—A good rich-coloured form of I. chrysographes with conspicuous yellow reticulation on the fall. Award of merit. Shown by Messrs. R. W. Wallace and Co.

IRIS DOUGRAPHES (Douglasiana × chrysographes).—A beautiful little flower of reddish purple. Award of merit. Shown by Messrs. Amos Perry.

IRIS FORRESTII.—A good yellow species of the sibirica section. Award of merit. Shown by Messrs. R. W. Wallace and Co.

IRIS SOUVENIR DE MME. GAUDICHAU.—A tall bearded flag with pale violet standards, deep violet falls and a golden beard. Award of merit. Shown by Messrs. R. W. Wallace and Co.

PYRETHRUM MRS. JAMES LEAKE.—Clear rose flowers borne on stiff, wiry stems. Award of merit. Shown by Mr. J. Leake.

PYRETHRUM PRINCESS MARY.—Good large double rose-coloured flowers borne on stiff, wiry stems. Both the above should prove excellent for cutting purposes. Award of merit. Shown by Mr. J. W. Wilkinson.

RHODENDRON PHILIP WATERER.—A bright rose-coloured hybrid with large trusses. As a late-flowering Aucklandii hybrid this should prove valuable. Award of merit. Shown by Messrs. John Waterer, Sons and Crisp.

TROLLIUS LEDEBOURII GOLDEN QUEEN.—A deep golden orange "globe flower" which should become very popular. Award of merit. Shown by Messrs. A. M. Ladhams.

ORCHIDS

AWARDS OF MERIT.

ODONTIODA LAURA GERRISH'S VAR. (O. Brewii × O. Coronation), from Mr. R. Gerrish, Milford Manor, Salisbury (gardener, Mr. Sorrell). In form and colour this variety surpasses previous results. Segments roundly formed, thick in texture, deep crimson-red colour, except for the rose-purple labellum. The spike carried eleven flowers.

CYPRIPEDIUM GODEFROYÆ LEUCOCHILUM VAR. EDWARD MARSHALL, from Messrs. Sanders, St. Albans. One of the best forms of this elegant species, segments of unusual breadth, the sepals and petals veined and spotted with maroon-purple, the labellum cream coloured and unspotted. In past years this plant has been regarded by some cultivators as a natural hybrid, but its true specific nature is now generally acknowledged.

Groups of orchids were exhibited by Messrs. Sanders, Messrs. Cowan and Co., Messrs. Stuart Low and Co., and Messrs. Charlesworth and Co.

GERANIUM ANEMONÆFOLIUM

ALTHOUGH this noble species has been in cultivation in this country for close upon 150 years, it is still rare in gardens and rarer still in the lists of nurserymen. It is difficult to account for this, for G. anemonæfolium is not less amenable to life in our gardens than a good many others—Traversii and cinereum, for example—which are much more often seen, and it is, moreover, a plant of most singular beauty and grandeur. Further, G. anemonæfolium is an evergreen the splendid foliage of which alone might claim for it a place as a border or woodland plant in the best of company. No species is more easily propagated (by seed), and in any well drained soil it is, as I have inferred, quite reasonably hardy.

This is a Maderian perennial species which, from a short, woody stock with a large round head like the "flower" of a globe artichoke in pale green, sends up a number of handsome, palmate leaves, big and sappy and glossy green, on thick, rigid stems. These grow all winter during mild weather and throughout the spring, until the plant, well matured, presents a dense mound of foliage some 3ft. across and nearly as high. Well above this in the later spring stand the many-branched flower-stems, which, like those of the leaves, are covered with iridiscent fur. Each extremity ends in a pair of flowers of a most attractive, full-toned, yet clear rosy crimson which darkens to a ruby eye. (The only other flower which I can recall to which the blossoms of G. anemonæfolium might be likened in their peculiar colour and texture is that of Oxalis floribunda.) These beautiful flowers are yielded in extraordinary abundance throughout the summer and often well into autumn. We find this splendid geranium long-lived in any free soil. It is, I think, the better for a little shade from the noonday sun, and it is as well to have a few large stones placed around it in windy situations. N. WALES.

THE PARIS SPRING HORTICULTURAL SHOW

BY CHARLES LERAY.

ABOUT the same time as the Chelsea Show, there took place in Paris, from May 23rd to June 1st, the great French Spring Horticultural Show. The site is the same as in pre-war days: the "Cours la Reine," along the river Seine, close to the well known Champs-Elysées. The duration is extended, but the growers make up for it by exhibiting mostly plants grown in pots and replace withered cut flowers whenever necessary with fresh material. Hydrangeas, roses, rhododendrons, annuals, biennials and vegetables were great features.

As is usual in French, and most of the Continental shows, the different exhibits were arranged on the ground, with little or no staging, so as to give the whole scene an harmonious and natural aspect. Hardy plants were few owing to the fact that they prove more satisfactory under the English climate and therefore are not so popular in France. On the other hand, annuals and biennials were numerous and particularly brilliant.

A few words on the main exhibits may prove interesting.

Messrs. Vilmorin-Andrieux and Co., of Paris, had a great and important display (see foreground of illustration) of annuals, biennials and perennial plants in the shape of a formal garden with grass or gravel paths. In side beds were many irises, for which the firm is famed, together with sweet peas from outdoor planting and numerous vegetables of the very best quality.

Next in importance came the exhibit of Messrs. Moser and Sons, of Versailles, consisting of quantities of hybrid rhododendrons, many of them large specimens 8ft. to 10ft. in diameter, along with aquatics and roses of all classes. Very brilliant in their stands were the new pernetiana roses, Reims and La Champagne, shown in great masses and to the very best advantage.

Messrs. Croux and Son, of Chatenay, were very close competitors also, with hybrid rhododendrons of large size—several of which received awards as novelties—and Azalea mollis hybrids of most brilliant colouring, the whole making a grand display.

Hydrangeas were very brilliantly represented in the stand of M. Mouilliere, of Vendôme; this exhibit consisted of large masses of Maréchal Foch, bright pink, turning under the usual treatment into a lovely blue; Mrs. H. J. Jones, a novelty with bright pink flowers of large size; Mme. Ph. de Vilmorin, another novelty with bright pink flowers shaded green, and so on. M. Cayeux, of Le Havre, another great raiser of these plants, had Ginette, a new large-flowered white; Sensation, pink shaded purple with individual flowers 3ins. across; Matador, very deep pink, etc.

Roses, besides those of Messrs. Moser and Sons already mentioned, were mainly pot plants, from Messrs. Defresne and Leveque, Parisian growers; the former including the curious and beautiful variety Eugene Barbier, the first H.P. hybrid of yellow colouring ever produced. Messrs. Nonin and Son, of Châtillon-sous-Bagneux, staged many varieties of interest, especially their new Wichuraiana hybrid, Châtillon Rose, of pink colouring, besides novelties of other growers. Buisson d'Or, a hybrid of Mme. Edouard Herriot and a form of Rosa lutea, came from M. Barbier, of Orleans, and created a sensation owing to its distinct and showy appearance.

Messrs. Cayeux and Le Clerc, of Paris, concentrated all their efforts on irises, of which they had a fine show. Their own varieties, Peau d'Ane, reddish; Le Vardar, lilac pink; and Gloriæ, violet, were worthy of all praise. The same firm showed several beds of annuals.

Hardy plants came from Messrs. Ferard and Laumonnier, of Paris, in some numbers, but their setting might be criticised, at least by an Englishman. An award of merit was granted to Geum Lady Stratheden, a valuable plant, which is being rapidly propagated in France.

Pelargonium zonale, as usual, was the speciality of M. Poirier, of Versailles, the veteran grower of that plant. Marquise de Moys was a fine pink and Mme. Gaston Beaumont a rich salmon. M. Chaubert, of Orleans, showed a good novelty of his own in Pelargonium grandiflorum Mirobolant, of bright pink colouring. Begonias, as usual, were shown by several growers.

Among the stove and greenhouse plants the orchids, though comparatively few, included a good many interesting specimens. The prize for the best orchid of the Show went to Lælio-Cattleya Ras Taffari, a showy hybrid of pink colouring, labellum violet purple. Masdevallia Harryana, of curious strawberry red colouring, Brasso-Lælio-Cattleya Jupiter, pink, labellum pink and purple, large flowers; Cattleya Mme. Auguste Gauthier, a new white hybrid, were also worth noticing. Gloxinia allied to Dircæa macrantha, of bright scarlet tint, came from M. Vallerand, of Taverny; also Begonia Rex. These last plants were also shown in excellent condition by M. Chantrier, of Mortefontaine, together with a beautiful collection of Caladiums and that rare palm, Pelagodoxa Henryana, native of the Marquise Islands. Carnations were few and all with the split calyx generally found on the Continent, so little need be said about them.

Ornamental trees and shrubs, including topiary and fruit trees were sent, as usual, from different quarters and were staged in the outside gardens. Fruit trees were finely represented in the exhibit of M. Nomblot-Bruneau, of Bourg la Reine, who had forced cherry trees, plum trees, etc., and trained fruit trees of all kinds and shapes. Forced fruits were shown in fine condition by M. Parent, of Rueil, who had first class Amsden and Halle's Early Peaches, plums, raspberries, and so on. In the vegetable exhibits, several bunches of asparagus were conspicuous, one of which weighed over 15lb. and was formed of thirty-one stems. It was a product of Argenteuil, the home of the asparagus industry, near Paris.

PART OF THE MAIN TENT AT THE PARIS SPRING SHOW.

In the sundries section, important as usual, automatic watering appliances were shown in quantity, some of which, intended for market growers, send artificial rain as much as 150ft. wide and run automatically to and fro in the garden on rails. Smaller apparatus, all built on the rotative system, with long revolving arms, intended for lawns, or smaller gardens, and watering about 30ft. to 50ft. wide at a time, were also on view. These appliances are the outcome of the abnormally dry summer of 1921, when many growers were brought next to ruin owing to their inability to give sufficient water to their crops in a cheap and practical way.

CATALOGUES RECEIVED.

Messrs. Barr and Sons, 11-13, King Street, Covent Garden, London, W.C.2.—Vegetable Seeds for June Sowing; Flower Seeds for the Rock Garden.

CORRESPONDENCE

SOLDANELLAS ALPINA AND MONTANA.

SIR,—*A propos* of Mr. Stuart Thompson's reference (page 389) to my note regarding Soldanella montana (page 344), Farrer, in his "English Rock Garden," gives the distinguishing differences for S. montana as "singleness of tuft or clump" and "leaves usually with a certain amount of vague scalloping at their edge." He also says S. montana is "a species that has so undeservedly been obscured by its inferior cousin that in most popular handbooks . . . there is no mention of it at all, despite its unquestionable regality in the race." In Wagner's "Deutsche Flora," S. montana is stated to have rounded leaves with shallow notches, flower stalks downy with short glandular hairs, stems at flowering time 15cm. high with three to ten flowers; habitat shady woods. I have a plant that I take to be S. montana which, from a gardener's point of view, is very different from S. alpina, as, besides its extra size, it has remained one tight clump and every year produces its flower stems very freely all in a bunch, instead of being spaced out in the same way as S. alpina. This spring suited my soldanellas splendidly, and they produced larger leaves than I have ever seen them do before, S. alpina being up to 1½ins. across and the supposed S. montana up to one and eleven-sixteenth inches across. —R. B. C., *Northumberland*.

DAFFODILS WHITE SENTINEL AND MITYLENE.

SIR,—Even now an error remains in Mr. Jacob's correction as to daffodil raising (page 411). The two very beautiful Leedsiis in question are *White* Sentinel (not *Sentinel*) and Mitylene. It is as well to be exact.—F. HERBERT CHAPMAN.

DEPTH TO PLANT CROCUSES.

SIR,—In reply to "Crocus," (page 344), I have burrowed down to our corms in several places and have found that in every case the Dutch have about 4ins. of soil over them. The species like Sieberi, Tomasinianus, etc., have rather less. I have just consulted some text books and find that they advocate varying depths from 3ins. to 5ins. Nothing could be better than our beds of Maximilian, so "Crocus" may safely increase his depth if he wishes to do so. I would suggest Hero as a very dark purple. It is the darkest in our collection. The colour is solid and shining.—JOSEPH JACOB.

STATICE PROFUSA.

SIR,—This represents a class of plant that was grown with much care and in considerable numbers by the gardeners of the gentry towards the end of last century. Plants were raised from cuttings and from seeds. Indeed, S. profusa was a hybrid between S. puberula and S. macrophylla, both from the Canary Islands. I have seen a plant of S. profusa that measured 4ft. across, though only about 1ft. high or less. Instead of being divided, it was put into larger and larger vessels till it reached the above dimensions. It must have been many years of age, for this class of plant does not multiply fast. Plants of it and some of the other old favourites were shown by Messrs. John Forbes, Limited, at Chelsea. The statices had much to recommend them in private establishments, because if they did not grow rapidly they were very durable in the conservatory and greenhouse. It took some time for the flowers to expand, after which the partly blue calyx remained in perfection for many weeks together, and the plants were not removed from the show house till the calyx became discoloured with age. The flowers were quite suitable for cutting, or for drying as everlastings, but cut flowers were not used in such quantity in the olden days as they are at present.—HORTULANUS.

GRAFTING PROBLEMS.

SIR,—A year or two ago I wrote some correspondence on experiments in grafting pear trees. Readers interested in fruit may

PEAR DOYENNE DU COMICE UNGRAFTED.

remember that I mentioned the case of a grower who put grafts of Glou Morceau on every third or fourth tree of a flat of Comice, with the object of pollinating the flower.

The surprising result was that the grafted trees began to show better crops, before the grafts had time to produce bloom, showing a strong influence long before cross-pollination was possible.

We repeated the experiment on a small scale with similar results. We have now two

DOYENNE DU COMICE GRAFTED.

trees of Comice side by side of the same age, and the one in which we inserted three or four grafts of Glou Morceau has at least five times as much bloom as the other. Not being Woburn pupils, we have not counted the trusses, but the difference is so striking as to be obvious to the most careless observer. The most curious point is that the improvement is not confined to the grafted branches, but the whole tree is pretty well equally covered, while the ungrafted tree is only sparsely flowered.—C. E. PEARSON.

GARDEN LABELS.

SIR,—The naming of plants is a vexed question, and labels, like lawyers, are necessary evils. I must frankly own there is a great deal to be said in favour of the numbering system as advocated by the Rev. Edward S. Lyttel. The plants in my garden, on the other hand, save for stray new-comers, have to live without labels, sometimes they don't even live then. It is all but impossible to have a garden beautiful if it is plastered over with conspicuous tally-pins; then it becomes more or less a botanical collection. No more than you have a garden with a greenhouse blazing in full view—for example, the Palm House at Kew—scintillating in all bulbous, bloated ugliness. Why, surely the illustration Fig. 2 on page 111 is of no decorative merit, and from a botanical point of view only tends to lead to confusion. Far better arrange the plants in rows in the rockery, if you will, 9ins. apart. It could not be worse than depicted, and the plants would be more readily distinguished.

Mr. Gerald Hillier and "G. G." seem to be viewing the label question from different points of view. The former I take it from a business point of view, where names may be indispensable for his clients, but this is not applicable in the same degree to private collections. [For example, he mentions "legible labels on the higher part of the rockery garden, so that anyone standing on the path could decipher them." In a private rockery garden of any size this sort of disfigurement is quite out of the question. Why, one's friends would be better to go round armed with a telescope.

Your correspondent "G. G." talks about his preference for large labels, and petty economy in labels, much preferring the former, neatly and plainly written. I rather fancy the advertisements of liver pills, etc., which disfigure the country at the railway side while travelling north from London must appeal to him. They are quite plainly written, and I presume neat and only in proportion to their surroundings. Nor can I understand why "labels bearing numbers which are duplicated in a private book" should be "an eyesore and vexation to the visitor." Bless my heart, they can hardly be seen among the plants, but that, however, may be their failing. I grant "G. G." that, as mentioned by the Editor, in wet weather the book is a little awkward, but I will endeavour to point out some of the advantages of using a number. Besides, a dirty wet day is not everyone's choice to meander about and enjoy a garden. Again, "G. G." says "the Rev. Edward Lyttel's system is a laborious one." Let us see. He stamps the required pieces of zinc, large or small to suit the situation, with numbers, and opposite the same number he writes in his catalogue book the name of the plants and inserts the numbered piece of zinc beside the plant. That's all. This label lasts indefinitely and can be used to name any other plant, of course the name in his book opposite that number being altered accordingly.

Now for one of Mr. Hillier's labels. "After the names of the plants have been stamped on the lead [the chances are ten to one, some of the letters upside down, certainly all higgledy-piggledy, for this stamping is an acquired art] the labels are rubbed over with a rag smeared in turps [doubtless the rag cannot be found and the bottle containing

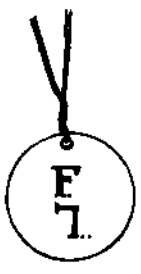
Digitized by Google

the turps will either have been broken or upset] and polished with a dry scrubbing brush [this is an article which can disappear in an amazing manner] then the letters are filled in with enamel paint [doubtless the lid will have been left off the enamel paint and it is hard and dry with possibly a dead mouse in it] a pointed stick being used for this purpose [this is certain to have disappeared, and another must be made] and such a label will last for three years." I really should have thought that after all this trouble it would have lasted throughout eternity. I hazard the opinion that if an ordinary paper garden label be rubbed over with white lead with the forefinger (which latter does not often go amissing), and the name immediately written in pencil and tied or nailed to a stick, it will last for some four years.

I must really congratulate "G. G." on having read for forty years and never having read weaker arguments than those advocated by our mutual friend, the parson. As he has evidently never tried the numbering experiment, and I even question if he has grasped the idea, he is but ill-qualified to write so dogmatically on the point, and in doing so he might almost have favoured readers with his full name. Mr. Hillier was quite willing to be "hauled over the coals" for his remarks, and I presume I will require to stand a good deal of "snash" for my views on the subject, though I trust the Rev. E. Lyttel will, like a sportsman, come to my assistance.

Is it not possible "G. G." has been emboldened by the Editorial note in your issue of April 12th, which evidently has been written under a misapprehension, to a certain extent at least? It is only a strong man who can own defeat, a weak man is never wrong, and as our Editor is of the former class, we may safely await his further mature deliberations. As already indicated, I have used the numbering system for many years for my "rhodos," and find it works most admirably, and doubtless it would do equally well if applied to border plants.

The following is the method employed. Small round discs of lead are stamped out the size of a penny piece and about the same thickness. A hole is punched near the edge, through which a light copper wire is passed to be attached to the shrub, giving it a few twists to keep it in place; then with a punch the required number is struck on it and above is marked the first letter of the rhodo's name, as per sketch herewith.



This is entered in a small handbook with the letters of the alphabet at the side, and on turning to F.7, it reads: "Falconeri, bought from Reuthe, December, 1917, price 5s. Blooms in May, rather tender, leaves large and magnificent, but flowers disappointing, plant shaded from morning sun and give winter protection." Should the making and stamping of the discs be too much trouble, then arrange with your seedsman to do so. They are much less expensive than stamping long flower names, such as Gypsophila paniculata flore pleno. The discs are better to be fixed on a stout branch and, if possible, where it forks, thus preventing slipping down, and it can be more loosely tied, as also always at one side of the shrub, be it north, south, east or west, thus making the disc more easily found. The reason for putting the first letter of the name on the label is that it helps to remind one of the name of the plant, also if you are from home and a friend asks you if you can grow Falconeri or have Falconeri, you instantly turn to the letter F and read your notes on No. 7 and its behaviour, if you have it, or, if not, you can perchance give it a trial, which thus saves searching through a long list of numbers for your plant. In your own grounds a friend armed with your rhodo. book has no trouble in identifying the plant, and from the book finds where it was bought, the price, its time of blooming, its tenderness or otherwise, its requirements, and can judge from these if he ought to try it or not. If you happen to be from home your gardener has only to look over his copy of your book and see which plants require protection. It is quite impossible to recollect all these things without any note of them. All this clerical work, so utterly opposed to the idea of a garden, is kept in the background, but works wonders all the same.

No; I think if "G. G." considers the matter again carefully, he will find there is some sort of method in the madness. The promoter of the Daylight Saving Bill was jeered at for years, yet many a man has had a statue raised to his memory who had less reason to deserve it. Pray do not let "G. G." go away with the idea that he is going to be called upon to subscribe for a statue to the Rev. Edward Lyttel. That would be going to the other extreme according to JOHN A. HOLMS, *Formakin, Bishopton, Renfrewshire.*

A PORTION OF THE LARGE PATCH OF DAPHNE CNEORUM.

A WONDERFUL PROFUSION OF DAPHNE CNEORUM.

SIR,—I enclose a photograph of Daphne Cneorum growing in our garden which may be of interest. There is a smaller clump than that illustrated which is about 5ft. in diameter, and is from three small plants brought from Devonshire in 1915. It is in the hottest, sunniest and driest part of the garden. From these three plants about a dozen layers were taken the following year, and these have produced the larger patch, which now covers an area of about 80 sq. ft. This large patch is partially shaded by a large apple tree. There is no lime in the soil, and no peat or leaf-mould has been added except a little of the latter just on the outer edges where the clumps are encroaching on the paths. There are plenty of large flattish stones among the plants, which apparently they like. During the 1921 drought I took great pains to keep the plants always moist, but before that neither clump received much attention in this or any other way. I have planted several more clumps, all of which promise to do equally well. One of them, from six cuttings taken in my Paris frame the year before last, is looking extremely healthy and throwing up a mass of young shoots. This one is in the rock garden, the soil of which is largely composed of mortar rubble. A delightful feature, which is only noticeable in large clumps like these, is that the plant never looks untidy. The flowers, when dead, hardly shrivel at all, and seem to be hidden and pushed off by the numerous young shoots which spring up round each flower head. All one notices is that the sheet of pink gradually changes into a thick mass of young green shoots.—H. S., *Bristol.*

RHODODENDRONS FOR AMATEURS

THERE is no group of hardy plants about which public interest has increased so much in recent years as rhododendrons. Soon after the middle of last century they began to acquire a standard place in gardens as about the most dependable of evergreens that combined fine foliage with a noble blossoming. But in those days the word rhododendron did not mean very much; nothing more, in fact, than a few species and a comparatively small number of easily grown hybrids raised from them. One might in a fair-sized garden then have grown every known rhododendron without difficulty. Even when the species found in the Himalaya and introduced by Sir Joseph Hooker in the early "fifties" had attained maturity the situation had not altered much. Matters have changed to-day. The botanical exploration of Western China, Tibet and Upper Burma has created a very different situation. It has resulted in the introduction to gardens of hundreds of species new to science and in the exhibition of the genus in many entirely new forms of growth and leaf and in colour of flower. With this enormous accretion of material the cultivation of rhododendrons as a whole is no longer the simple matter it was in our grandfathers' time. In these days anyone who wants to grow a really representative collection is confronted by a number of problems in satisfying their needs.

Except for the great works by Mr. J. G. Millais, which are too sumptuous and too expensive for the majority of us, no book on rhododendrons is available which can claim to be up to date. There was therefore a great need for a work on this genus, published at a price within the means of all. All those who take an interest in rhododendrons are to be congratulated that the task of producing such a work was undertaken by Mr. Cox. In the rhododendron

Digitized by Google

world he is known as one who has made a special study of these fascinating shrubs, who has seen them growing in their native wilds, and who has grown them in his own garden. To these qualifications he adds that of an enviable literary gift and the faculty of marshalling his facts in a most interesting way.*

In his introductory remarks on the genus the author states that the central home of the rhododendron almost certainly lies in that area where Tibet, China, Upper Burma and Assam meet.

> If you can imagine that area to be the palm of a very large hand, the Himalaya will act as the thumb stretching to the west, the Irrawady-Salween and the Salween-Mekong divides as very definite first and second fingers running north and south. The third finger is the Mekong-Yangtze divide . . . while the little finger is lost in a tangle of contorted ranges stretching out through Hupeh, Szechuan and the Tibetan Marches.

Mr. Cox then develops a very interesting and, to my mind, satisfactory theory explaining how the progeny of a rhododendron situated originally on the palm of the hand have gradually spread their several ways down the fingers and, encountering differences of soil and climate, have in the course of, no doubt, thousands of years gradually acquired differences in habit, leaf and colour of flower, yet have each retained unmistakably many of the characters of the common ancestor. This theory is put forward to account for the extraordinary multiplicity of species, or forms, or whatever one likes to call them, found in this great rhododendron region, and at the same time to explain the close relationship many of them palpably bear to each other although their native localities are now so widely separate. In his review of the species the author has adopted the wise and convenient plan of assembling and discussing them under their various groups or "series." Thus we get the Fortunei series, the barbatum series, neriiflorum series and so on.

Mr. Cox's book is intended more particularly for amateurs and for people who are beginning the cultivation of rhododendrons, especially those beginning in a small way. It is written, consequently, in simple, untechnical language and, while it deals very fully with cultural matters, it makes no claim to be a comprehensive review of all the species. That, indeed, would not only be impossible in a work of this size, it would be undesirable for the class of reader the author has in view. In these days the number of hardy trees and shrubs in general, and of rhododendrons in particular, that are available to cultivators is so great that there is nothing the beginner or the small amateur so much desires and needs as an indication of the kinds he had best commence with. In this book he will find carefully chosen lists of rhododendrons of various sizes and for various places. Greatly daring, Mr. Cox has even ventured to enumerate the twelve best species. He tells us frankly this list represents his personal predilections and that possibly no one else will agree with him as to the whole twelve. I suppose to get as near as possible to a solution of that problem one ought to institute a kind of plebescite among rhododendron growers. Personally, I would displace auriculatum from his list in favour of Aucklandii. But for some reason Aucklandii (or Griffithianaum) gets scant notice in this book. Yet it has played a great part in the evolution of the best garden hybrids. In the list of species suitable for rock gardens, too, I would certainly have put in impeditum, which for neatness, hardiness and freedom of flowering is not surpassed.

Beginners will find an extremely well chosen list of fifty to sixty kinds of hybrids, with information as to the hardiness of each, colour of blossom, time of flowering, etc. As garden plants these hybrids are almost invariably satisfactory, being easily grown and having little of the waywardness that unfortunately many of the true species display. Personally, I believe the beginner will do best to make a choice from this list of hybrids and put his main reliance on them, especially if he is not fortunate enough to have his garden in the south or west. He may be sure they will not fail him. At the same time he should, with the aid of this book, gradually feel his way among the species, the best of which have an air of distinction and breeding few hybrids seem able to equal.

The author is to be congratulated on producing a very useful and charmingly written book, interestingly illustrated by reproductions from photographs, admirably printed and bound and, what is too rare among gardening books agreeably free from errors in the spelling of plant names and similar minor blemishes. W. J. B.

* "Rhododendrons for Amateurs," by E. H. M. Cox. (London, *Country Life*, Limited.) Price 5s. With illustrations.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Turnips.—After this date turnip seed may be more liberally sown, and with every chance of success, providing the fly is kept at bay during the seedling stage. Sow in lines 1ft. apart, and well thin the seedlings directly they are large enough. Soot and lime sprinkled along the rows will generally ward off the fly.

Broccoli, etc.—Every opportunity should be taken during showery weather to put out broccoli, kales and savoys. Seeds of small varieties of cabbage, and coleworts may be sown, and these will furnish good heads later on. Seed of lettuces, radishes, etc., ought also to be sown.

THE FLOWER GARDEN.

Aquilegia glandulosa.—This is a splendid columbine for the rock garden, and may be raised from seed. It was seen in fine form at the recent Chelsea Show, and the sapphire blooms with white centres were most attractive. The seed can be raised in a cold frame and the seedlings should be transferred to their flowering quarters while quite small.

Lupins.—The shrubby Lupinus arboreus has a tendency after a few years to decay, the result being rather unshapely specimens. To remedy this, a fresh batch of plants may be raised from seed, or cuttings can be rooted just after the flowering period. Select short-jointed shoots, and if inserted in sandy soil they will form roots if placed in a hand-light or cold frame. Of the herbaceous varieties every gardener should make a point of rearing some of the fine pink forms which have been frequently shown this year.

Brompton Stocks.—During the next few weeks seeds of Brompton stocks should be sown to produce a display in the spring and early summer months. It may either be sown outside or in a cold frame, but if the latter is chosen the lights should be dispensed with directly the seeds have germinated. When the seedlings are large enough, transfer them to their final quarters if the soil is light and well drained, but where it is of a heavy, wet nature, it is better to winter the plants in a cold frame. A reliable mixed strain will give excellent results.

VEGETABLES UNDER GLASS.

Cucumbers.—The plants put out in the early spring having produced good crops will have ceased to be profitable, therefore should be removed at once. Wash down the house and replace the old soil with some turfy loam. When this has become warm new plants may be set out, a distance of 3ft. between each plant being ample. Plants in full bearing will be benefited by an occasional top-dressing of loam, and a little decayed manure. It is more beneficial to afford light top-dressings at short intervals, than to give a large quantity of soil at one time. A moist atmosphere is essential, and about three or four o'clock in the afternoon the house or frame should be thoroughly damped down with the syringe or watering can and then closed. White fly should be held in check by vaporising the house with a reliable fumigant. Continual warfare should be made on this pest or the plants will be ruined.

Tomatoes.—Plants in pots that are producing a crop will take copious supplies of water, and it is necessary for the roots to be kept more or less moist. Until the fruits begin to colour, liquid manure, and an occasional sprinkling of some fertiliser may be given. Other plants in borders will be less trouble, and will produce a better crop. Remove all side shoots as they appear and make the main shoot fast to the supports.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Jerusalem Artichokes should, like the potato, have the soil drawn up on either side of the lines. This earthing-up is sometimes done in the case of broad beans and also to lines of peas before the supports are placed in position.

Celery.—This vegetable when grown on heavy soil may not always give satisfaction. In such cases I advise not growing in trenches. By the following method good plants can be grown: Lines should be marked out for the

Digitized by Google

plants and grooves made. The soil in the grooves should be turned over and leaf-mould, rich potting soil or well decayed manure incorporated with the soil as digging proceeds. The plants should be set out on the prepared lines and when sufficiently grown be neatly tied and blanched by having the soil banked up on either side of each row. One great advantage of growing celery without trenches is that the plants are more easily got out from the soil when required for use.

Lettuces of the Cos type should be lightly tied up with matting in order to assist in the blanching of the inner leaves. Seedlings should be set out in lines marked off at 1ft. apart on any spare ground, or they may be set between the lines of Brussels sprouts. Well water after they are planted, and occasionally afterwards—if the weather is dry—until they become established.

Peas.—On light soils where crops suffer in dry seasons it is advisable to place a mulch of farmyard manure along each line. This mulching should be done after the ground has been well moistened by rain.

Spinach.—Spent crops which have been growing between lines of peas should be cleared away. This will allow of a freer access for pod picking when the peas are ready.

THE FLOWER GARDEN.

Carnations.—Where the buds are clustered together, as they usually are, thin them out. The buds left should be so placed that 6ins. or more of stem shall be obtained when cutting the flowers.

Seed Sowing.—Seed of Canterbury bells and the chimney campanulas are best sown in boxes containing medium fine soil and placed in a cold frame. Other seeds to sow in boxes include double daisy Firefly, polyanthus Munstead strain, from which many choice colours will be obtained, and violas. The following may be sown on the open border in lines drawn out at 1ft. apart: delphiniums, Alyssum saxatile and sweet williams.

Thinning Seedlings.—Hardy annuals should be well thinned out so that the remaining plants will have sufficient space to develop and give of their best. Seedling wallflowers should be set out 6ins. distant from each other in lines 1ft. apart.

THE HARDY FRUIT GARDEN.

Apples.—This year the trees have borne a wonderful profusion of blossom, and now the fruits should be properly set. Where overcrowded they should be well thinned, so that fair crops of good-sized apples will be obtained, which is more to be desired than a large quantity of small fruits.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Heeria elegans.—This dwarf trailing plant is very useful for furnishing small hanging baskets, as it produces large rosy red flowers in great profusion during the summer months. It succeeds quite well in an ordinary greenhouse, and is easily propagated by means of cuttings at any time. The cuttings root freely in sandy soil if placed under a bell-glass in a cool house.

Rehmannia angulata if treated as a biennial is very useful for conservatory decoration. Plants raised from seed sown at this time will flower towards the end of May next year. These plants also have the merit of flowering for many weeks and when young may be used for the stages; while, as they increase in height, they are useful for furnishing the beds. Seed should be sown at this time in a cool greenhouse, and their subsequent cultivation carried out entirely in cold frames. The plants should be wintered in 48-sized pots and early in the New Year transferred to their flowering pots, which may be 6ins. or 8ins. in size. This plant grows freely in any good potting compost. There is a beautiful white-flowered variety in the trade, while the type varies a little in colour, thus seed should be saved from selected plants.

Hydrangeas.—Cuttings should now be secured from the best varieties. Most of the newer sorts have the advantage of flowering with greater certainty and freedom than many of the older varieties of H. Hortensia. Cuttings are best inserted singly in small pots, and they root readily in a close case with slight bottom heat at command. When potted on into 48-sized pots they should be stood in cold frames, in which they may be wintered, just protecting them from frost. With strict attention as regards watering the young plants can be flowered in this sized pot, but it is advisable to put a portion of the stock into slightly larger pots. For large specimens the plants should be potted on after they have finished flowering. Blue-flowered plants are always greatly admired, and this colour may be produced by adding iron filings to the potting soil. There are proprietary preparations sold, which if used according to instructions will produce the desired blue shade. Generally these preparations must be used right through the cultivation of the plants, and pink-flowered varieties are necessary for this purpose.

Hippeastrums.—Seed that has been saved from selected plants should now be sown in pans containing light soil, standing them in a warm house with a temperature of 60° to 65°. When large enough to handle the seedlings should be pricked off into pans, using a light rich soil at this stage. Afterwards, when large enough, they may be placed singly in small pots, or planted out in a bed with bottom heat at command. Whatever method is adopted, the plants should be grown on without drying off until they attain flowering size. Old plants should be encouraged to make all possible growth by feeding with diluted liquid manure and some approved artificial fertiliser.

Gilia coronopifolia.—Seed of this beautiful biennial should now be sown in a cool greenhouse. When large enough to handle, the seedlings should be pricked off into pans containing light soil and later on transferred to small pots. Well grown plants should be wintered in 48-sized pots, and during the winter should be kept on the dry side and well up to the roof-glass in a light, airy greenhouse.

Mignonette.—A sowing should now be made in a cool house or in cold frames in order to produce plants for flowering in the greenhouse during the autumn. The seed may be sown directly into the flowering pots if so desired. Firm potting and lime in the soil is essential for success.

J. COUTTS.
Royal Botanic Gardens, Kew.

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Daffodil Prospector (K. W.).—The rich deep colour of this shapely trumpet variety constitutes its special charm. It is an excellent doer and, what is such a valuable asset, it increases freely and makes fine bulbs. It should do well in any garden, but it will probably do best where the soil is on the light side and well drained.

FRUIT GARDEN.

Cox's Orange Pippin Apple (O. S., Torrington).—Our correspondent may plant any self-fertilising apple near the Cox's Orange Pippin. King of the Pippins is a good variety for the purpose, flowering at the same time, and its fruits, too, are richly flavoured, being, in this respect, a suitable companion to Cox's.

VERMOL kills worms and grows good grass.

All the famous GOLF, TENNIS, BOWLING and CRICKET CLUBS throughout the world use—

HE can only tackle them one at a time BUT—

VERMOL gets the lot.

VERMOL

The Worm Destroyer and Grass Tonic.

What users say of Vermol—

THE SUNNINGDALE GOLF CLUB

"VERMOL WORM KILLER has been used on this course for a number of years. When it is applied in warm, muggy weather and well watered in with a hose, no Sunningdale worm can resist it."

Abol — The Standard Plant Wash

Abol Non-poisonous Insecticide is a sure-kill for Green and Black Fly, etc., and is unequalled as a remedy for Mildew on Roses and other plants. It imparts health and vigour to the plant, and leaves the foliage beautifully clean and fresh.

Abol is perfectly safe to use on all flowers, fruits and vegetables, and will not harm the tenderest plant; has no unpleasant odour and will not damage paintwork.

Abol Non-poisonous Insecticide

Used in the Royal Gardens.

½pt., 1/4; pt., 2/2; qt., 3/4, ½gall., 5/3. gall., 9/6.

Write for descriptive folders to Nurserymen, Seedsmen, Florists, Ironmongers, Chemists and Stores.

In the event of any difficulty, please write direct to the Sole Proprietors and Manufacturers, Abol Limited, 9, Beltring, Paddock Wood, Kent.

Write for Guide to Garden Pests, Gratis and Post Free.

The Syringe with the Perfect Spray

Abol Patent Syringes give a perfect mist-like spray—strong, yet so fine that it does not fall at once to the ground, but hangs in the air, and so envelops the tree or bush. The spray may be varied from fine to medium or coarse, as desired.

No. 4 (1 x 14), 16/4
No. 5 (1 x 20), 21/-
No. 6 (1¼ x 20), 26/-

Bend attachment, for directing spray to undersides of leaves, not included, but extra 1/6.

Abol

Patent Syringes

Specially recommended by the National Rose Society.

WHY is "HOMES and GARDENS" such a Great Success?

BECAUSE it shows greater House Comfort & Convenience —with less Labour and Expense.

AN INSECT WASH WHICH NEVER FAILS

We say without reserve that the "ALVESCO" SPECIAL INSECT WASH will positively kill every form of insect pest and ***actually improve*** the health of the plant at the same time. Some supposed pest killers kill the plant as well. "ALVESCO" is accepted as the most efficient wash offered to horticulturists. It is safe and sure.

If your Seedsman does not stock "ALVESCO" SPECIAL INSECT WASH, send us his name and address.

ALVESCO

SPECIAL POINTS.
(i). It **does** kill insects.
(ii). It **does** help the plants.
(iii). It **does** save labour.

Obtainable from all Seedsmen or in case of difficulty write direct to:

MURPHY & SON, Ltd., Montlake, S.W.14

TREES AND SHRUBS.

Lime Tree Leaves (E. W. M.).—The curious growth on the leaves is caused by one of the gall-producing insects. The particular insect attacking the leaves enclosed is known as the "nail-gall." However, these pests do not appear to do much permanent injury.

Flemish Red Cherry (Felsted).—The birds do not eat the fruits of this variety while there are sweeter ones near. But in very hot weather they will attack the fruits. Birds eat the green fruits of strawberries in hot weather, as well as the ripening ones, and the green specimens are almost tasteless except for their acidity.

The Flowering of Hollies (L. D. G., Bagenalstown).—Holly trees are flowering with exceptional freedom in many gardens this year. The actual flowering will not distress the trees to any great extent, the harm will be an abundant production of berries on the female trees. The male and female flowers being usually borne on separate trees, it is the berry-bearing specimens which will require special attention. Assuming that both male and female trees are grown, the former being necessary for pollination, if not considered too big an undertaking with such old trees, it seems desirable to suggest the removal of a goodly proportion of the berries, unless the trees are very healthy. Mulching with old decayed manure and liberal supplies of water will be beneficial, as even during heavy rains very little finds its way through the foliage of densely-topped hollies. Failing well decayed manure, water with liquid cow manure, or apply bone meal, hoeing into the surface and water liberally several times. These are suggestions which can be adapted to local circumstances.

MISCELLANEOUS.

Various Questions (T. L.).—1, Reddish purple; 2, Ordinary garden worms not harmful; 3, Aquilegia flabellata; 4, Primula Wardii; 5 (a) Cotula squalida (feathery), (b) C. dioica.

Peat Moss for Mulching. (J. F. W.).—Peat moss, in the form of a mulch, would not be harmful to the plants referred to by our correspondent (Violas, Lobelia cardinalis, phloxes, and Nicotiana affinis). It is neat in appearance and conserves the moisture, which is the main object. Any mulch that "cakes" interferes with the passage of air which always follows water into the soil, and "caking" material prevents water entering evenly.

Names of Plants.—(E. M. R.).—Lonicera Maackii.——("Regular Reader," Windermere).—Ulmus campestris antarctica. Sow seed of winter spinach in July or August. ——("Constant Reader").—Cyrtanthus O'Brienii.——(W. L. T.).—1, Genista pilosa; 2, Saxifraga Andrewsii; 3, Antennaria dioica tomentosa; 4, A. dioica.——(J. A. E.).—1, Spiræa Van Houttei; 2, Allium ursinum.——(C. H.).—Staphylea pinnata.——S. H. B.—1, Iris graminea; 2, Galega orientalis.——H. P.—A, Syringa pinnatifida; B, Colutea arborescens.

OBITUARY

MR. HENRY NEVARD.

THE death of a well known rosarian in Mr. Henry Nevard, aged sixty-nine, of Colchester, occurred (following a stroke) on Thursday, May 22nd. The late Mr. Nevard was foreman to Messrs. Frank Cant and Co., Braiswick, with whom he had been associated for thirty-seven years. He was one of the old school of rose growers, a great enthusiast, with a thorough knowledge of the ancient as well as the modern roses, well known to many professional and amateur exhibitors, and very highly esteemed and respected by all who knew him. The deceased leaves a widow and a large family.

The Gardener's Greatest Difficulty

is to be able to give the plants which need feeding a complete food without any danger of injury and without any trouble

PLANTORA

SOLVES THIS PROBLEM

For being almost completely soluble it can be used with any watering can, leaves and blooms can be watered over without fear

PLANTORA

is a highly concentrated and complete Plant Food, rich to the last degree, inexpensive, clean, dry, odourless, colourless and non-poisonous. It induces roots to come to the surface and feeds them.

Price in tins **1/6** (to make about 35 gallons), **2/9** (to make about 80 gallons), **7/6** (to make about 240 gallons), and **15/6** (to make about 560 gallons).

BENTLEY'S WEED DESTROYER

(POISON)

Utterly destroys all weeds on **Garden Paths, Carriage Drives, Stable Yards, etc.**

Where applied no weeds can grow again for nearly two years. It is the most powerful and lasting, and its enormous sales during the past half century prove its unrivalled popularity. **Bentley's Weed Destroyer** continues to hold its premier position despite the growing number of cheap and inferior preparations. It is the most economical because it cannot fail if used as directed.

Royalty, the leading Nobility and Gentry, and the principal Corporations use Bentley's regularly.

CONCENTRATED (1 gallon to 80 gallons of water). 6 galls., **51/6**; 12 galls., **99/-**; 24 galls., **192/6.** In 6 gall. drums, charged and returnable.

POWDER (1 tin to 25 gallons of water). 4 tins, **13/2**; 8 tins, **25/-**; 12 tins, **35/9**; 20 tins, **57/2**; 40 tins, **110/-.** Tins free. Cases charged and returnable.

COMPOUND LIQUID QUASSIA EXTRACT (Non-poisonous)

The first Compound Extract of Quassia manufactured for horticultural use. Remains superior to all imitations. Meets all the requirements of a perfect general outdoor insecticide. Especially fatal to all forms of **Aphis,** also **Celery Fly, Turnip Fly, Onion Fly, Caterpillar, etc.**

It may be used **anywhere and everywhere** with absolute safety. One gallon makes 80 to 100 gallons of wash ready for use.

5 galls., **9/-** per gall.; 1 gall., **9/6**; ½ gall., **5/6**; 1 quart, **3/4**; 1 pint, **1/10.**

VITALIZER: A combined FRUIT, PLANT and VEGETABLE manure.

Contains all the necessary elements for feeding and stimulating all crops. Unequalled as an all-round economical fertilizer. Recommended particularly to those gardeners and growers who are obliged to depend mainly upon one manure. Far and away superior to the best of so-called Guanos.

1 ton, **£24 15/-**; 4 cwts., **25/-** per cwt.; 1 cwt., **26/6**; ½ cwt., **14/6**; 28 lbs., **8/-**; 14 lbs., **4/6.** Carriage paid on orders of 15/- and upwards.

Gardening of the Week	458

THE PURPOSE OF WISLEY?

ALONG with other representatives of the Press I was invited to Wisley on Monday, June 16th, in order to see what practical work the Royal Horticultural Society is accomplishing on behalf of its Fellows. On other pages of this issue will be found a few notes and a few pictures taken a week ago in the gardens.

I left Wisley with a feeling of delight at what I had seen, but at the back of my mind there is a perplexity about what the exact purpose of Wisley is supposed to be. I hope I may be forgiven if I am so bold as to state what in my mind should be the ideals aimed at in the Society's garden.

(1.) It should be the most beautiful and perfectly kept garden which soil, situation, climate, the influence of the Society, and money can make.

(2.) It should be run for the benefit of every Fellow of the Society, whether a specialist or a beginner.

(3.) It should be a garden in which Fellows can not only see plants well grown, but can also see them grouped together in their different genera so that they may judge for themselves in which direction their tastes lie and which variety or species they prefer. For this purpose it should contain both common and rare plants.

(4.) It should be a training school for those who hope to make gardening a profession.

(5.) It should grow and distribute plants not usually found in nursery gardens.

Now I shall be even bolder and try to point out how, in my estimation—I have an idea that I should write this article in the Chinese manner and say "in the knowing-nothing mind of this most ignorant and insignificant person"—Wisley occasionally falls short of the ideal.

(1.) Wisley is a most beautiful garden in a lovely situation. Owing to the sandy soil its cultivators naturally have to fight against certain drawbacks, but it is so beautiful that some parts might be better. This point is dealt with at greater length in the article on Wisley, but I will give one instance. The new heath garden lacks individuality; it is undulating, but the undulations are meaningless; they are either too high or too low. The formation of the ground is like the approach to a difficult green on a seaside golf course.

(2.) This is attempted and for the most part accomplished by the skill of the director and of the Wisley Committee, but surely too much attention is given to vegetable trials. The ordinary gardener is not interested in the fact that lettuce Tweedledum should be called Tweedledee. What he wants is a lettuce which is easily grown and good to eat and is easily obtainable either from one of the big houses or from his local seedsman. The Wisley vegetable trials do not tell him if variety A will flourish in his garden, but his seedsman usually can supply him with that information. Flower trials, on the other hand, are of great importance, because colour, form and shape all have to be considered, but who cares about the colour, form or shape of a leek?

(3.) Nothing could be better than the way in which berberises, cotoneasters and other plants are shown. They are excellently grown and are planted attractively in such a way that the merits and demerits of the different varieties and species can be judged from an individual standpoint. It is to be hoped that in time this method will be extended to other parts of the garden. There is a fine and effective grouping of irises planted in the same method, but it is a pity that new forms are not added as they come out. This is infinitely the best way of picking out plants for one's own garden.

(4.) With great hesitation I put forward the suggestion that students of an older age should be taken on at Wisley, or at any rate that they should be only taken on after two or three years practical work behind them. This suggestion is not made in any carping spirit, for from the results which may be seen at Wisley they are excellently trained and are willing workers; but I happen to know the scarcity of matured gardeners, not only in this country but in the colonies. Wisley holds a unique place in our gardens, for I believe that it is the only place where fruit, vegetables, garden flowers and rare plants are grown and scientific investigation is carried out in one establishment. It is so valuable in this way that in my opinion Wisley should finish off a student's training and not begin it.

(5.) On this heading I should keep discreetly silent, because I have a passionate curiosity about rare plants and I feel that Wisley should be the great distributing centre for all new importations; so far this has been the most neglected of its many branches.

After all Wisley is our heritage in the gardening world, and no garden is so good that there is no room for improvement. The war and its aftermath upset much in horticulture and there is little doubt that I am only voicing thoughts and intentions which the director and others who look after Wisley's destinies have had in mind for months past. If so, I hope I may be forgiven for making these few remarks. E. H. M. C.

A DISCOURSE ON NYMPHÆAS—I

BY F. LAPLACE.

MR. LAPLACE HAS RECENTLY RETIRED FROM THE ADMINISTRATION OF THE FAMOUS BAGATELLE GARDENS, PARIS. HE IS ONE OF THE GREATEST EXPERTS ON NYMPHÆAS.

IT is some forty years since the first varieties of nymphæas appeared in the collections of lovers of gardens. Horticulture owes to M. Bory Latour Marliac the introduction of these magnificent plants. It is, however, true that forty years earlier M. Tourrès, of Tonneries, Lot et Garonne, had obtained a few interesting seeds, but these have all disappeared from cultivation.

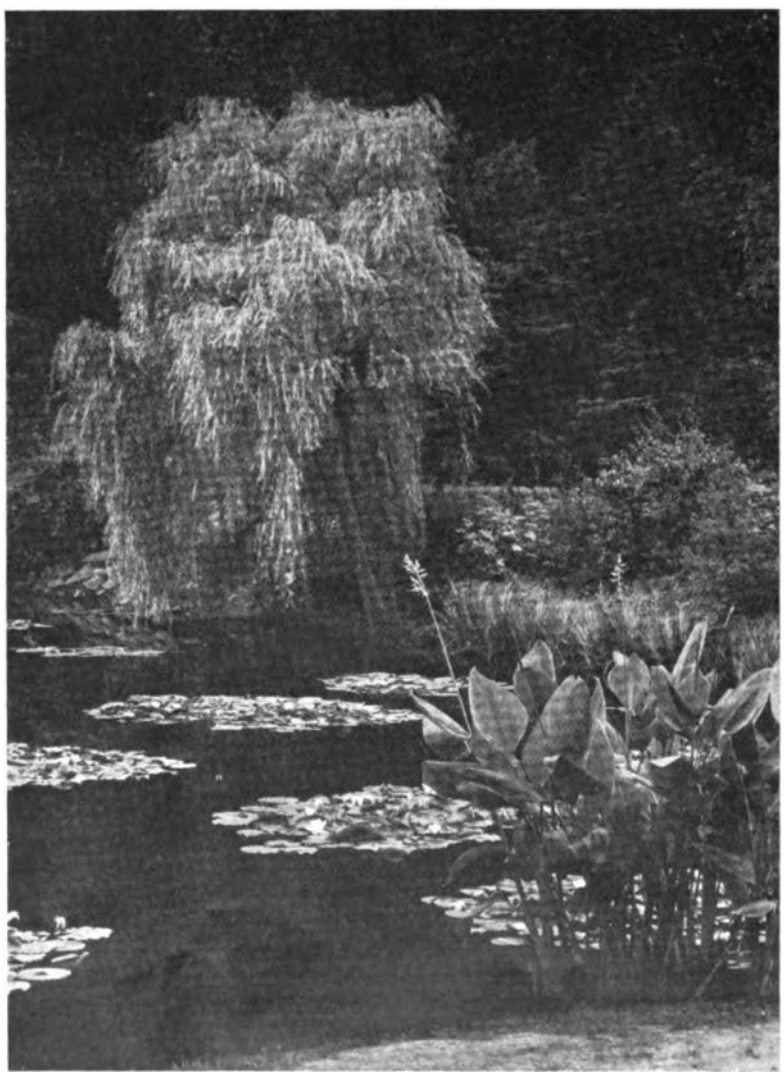
For a long time, M. Latour Marliac, who had once read an article by M. Lemaire in the "Illustration horticole" in which he said that it would be desirable to obtain hardy nymphæas as brilliantly coloured as the hothouse nymphæas, had hoped to realise this ambition. The introduction of half-hardy foreign nymphæas, such as N. mexicana (syn. N. flava) and others enabled him to produce plants which were hardy and of various colours. It appears that by using a foreign water lily with a red flower hybridised with N. alba he obtained his first hybrid which had a red flower; but this plant only lived a few years and it was not till seventeen years later that he was able to produce it again. This plant was never placed on the market. From time to time M. Godefroy Lebeuf succeeded in introducing from America, at very high prices for the time, a N. odorata with bright rose flowers. This plant had been for a very long time the property of a grower near Boston, who drew very handsome profits from the sale of the flowers. This plant seems to have been a natural variety of N. odorata. However this may be, this plant in the hands of M. Latour Marliac, hybridised by or with plants he had already obtained, became the parent of numerous varieties with rose, red or purple flowers; at the same time N. mexicana, by its descendants hybridised with the preceding plants, contributed also to the creation of some very fine varieties with flowers of a coppery hue.

The number of varieties put on the market by M. Latour Marliac is at present eighty, but this number does not represent the actual number of the varieties he has obtained, for a certain proportion are not sufficiently decorative in character. Situated at Le Temple sur Lot, Lot et Garonne, the establishment of M. Latour Marliac comprises about forty ponds, divided into more than six hundred compartments, fed by seventeen springs, the water coming out of the ground at an even temperature of 10° Centigrade.

The genus nymphæa comprises about forty species native to all parts of the earth. Although this number is small there are differences of character sufficiently important to admit of dividing the genus into five groups, these are:

1. Anecphia.
2. Brachyceros.
3. Castalia.
4. Lotus.
5. Hydrocallis.

From the horticultural point of view it is unnecessary to discuss all the types of nymphæa. In fact, it is only necessary to consider the hardy water lilies and a few foreign ones which are easy to cultivate either in the hot-house or out of doors in summer.



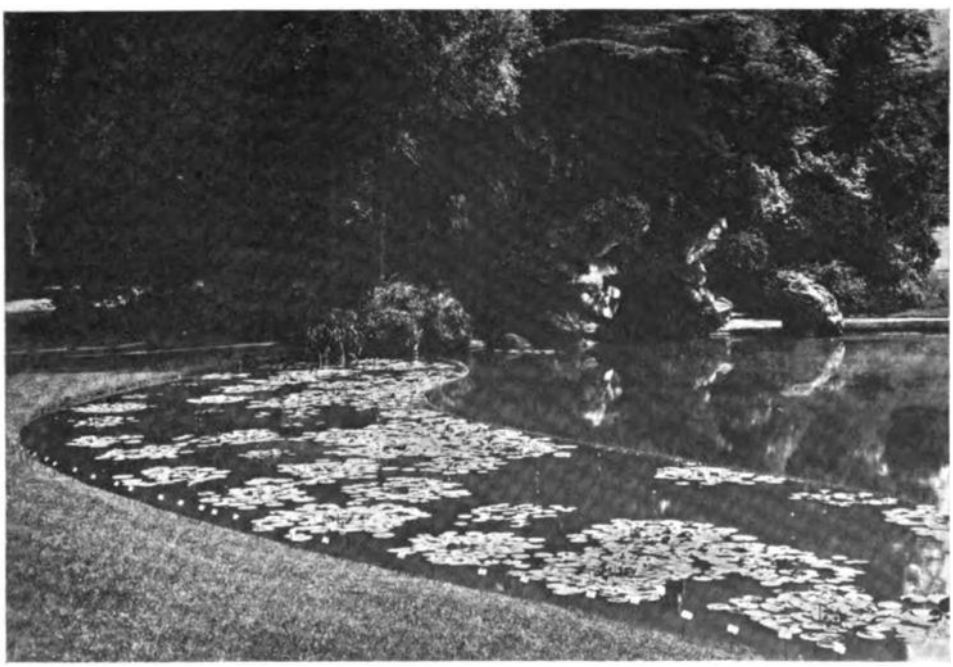
A PLACID WATER LILY POOL. NOTE HOW THE BACKGROUND IS IMPROVED BY THE WEEPING WILLOW.

The general characteristics of the genus are as follows: Water-plants having thick rhizomes, usually horizontal, but occasionally erect. These rhizomes orcrowns are covered with a number of marks corresponding to the insertion of the petioles and the peduncles; the rhizomes end in buds from which spring the leaves and the flowers (in some kinds the rhizome produces lateral buds); the petioles and the peduncles, which are cylindrical, vary in length according to the depth of the water, and the flower-bearing stalk opens on the surface of the water. In the section Castalia, of which the type is the N. alba of Europe, the flowers float; on the other hand, in the section Brachyceros, the flowers open 15c. to 20c. above the water. The stalks bearing the leaves are cordate or oval or circular and have at the base a sinus more or less open, the edge being sometimes serrated. The flowers are large, the calyx being composed of four sepals, green on the outside and more or less coloured inside; the corolla has three to five

Digitized by Google

rows of petals which vary in size according to the species. The sepals are very numerous and are attached to the seed pod, which is usually large and crowned with a disc bearing stigmata in several rows. Some of the outer stamens are more or less petalloid. The fruit when it has reached maturity contains a very large number of seeds arranged on transverse partitions. After fertilisation the flower stalk bends over and the fruit develops under water; when mature, the fruit bursts and the seeds are released.

A WELL-FLOWERED GROUP OF WATER LILIES.



WATER LILIES IN THE BAGATELLE GARDENS.

The hardy water lilies, both species and hybrids, belong to the Castalia section, and the few hot-house ones, which will be discussed later, to the Brachyceros section, of which the best known type is the N. capensis.

It will be convenient to pass rapidly in review the principal types which have contributed to the creation of the magnificent hybrid water lilies. These types are, as a matter of fact, very interesting in themselves.

First should be mentioned N. alba, Europe. This well known plant with white flowers, scented, varies slightly in size according to the regions in which it is found; the following varieties are fairly general in cultivation, minor, maxima, and candida, this last, which is often raised to the dignity of a species is really only a form of N. alba, and is native to Bohemia.

From Sweden N. sphœrocarpa rosea, has been introduced; this is considered as a variety of N. alba, though it is sometimes thought to be an autonomous species. This lily is extremely interesting on account of its magnificent bright rose flowers. It is very rare in cultivation and it has not, as certain writers maintain, contributed to the production of hybrids.

Close to N. alba comes N. odorata, a species of vigorous growth, native to the United States; the rhizomes are very branching and it has large white flowers, the petals being a little narrower than those of N. alba. This is a very hardy species and is represented in cultivation by a fairly large number of varieties, of which the most important are minor and maxima, both with white flowers, and especially rosea, with fine clear rose-coloured flowers.

N. tuberosa, is another type from the United States, also with white flowers. It is often cultivated on account of its great vigour and the size of its flowers; it is a fast grower and is even inclined to overrun, but it does not bear many flowers.

N. tetragona (syn. N. pygmæa) is also a charming small species from China with pure white flowers; it can be grown in small tanks.

Finally, N. mexicana (syn. N. flava) with its yellow flowers and its peculiar growth—it has no rhizomes, but forms a sort of tuberous stump which throws out a number of stolons—is a great favourite with growers.

The section Brachyceros is represented by a fairly large number of forms with blue flowers, as for instance, N. cœrulea, N. stellata, and N. capensis. Regarded by some botanists as distinct species and united in a single group by others, these plants have certainly some points of resemblance, but from the horticultural point of view are sufficiently different in regard to their size, habit and the abundance of their flowers. In a wild state and in cultivation some kinds have appeared with white flowers, some with rose-coloured ones, purple, etc.; this group consists of what are called half-hardy water lilies, and I will indicate later on some hints for their successful cultivation.

FORTHCOMING EVENT.

July 5.—Windsor, Eton and District Society's Rose Show.

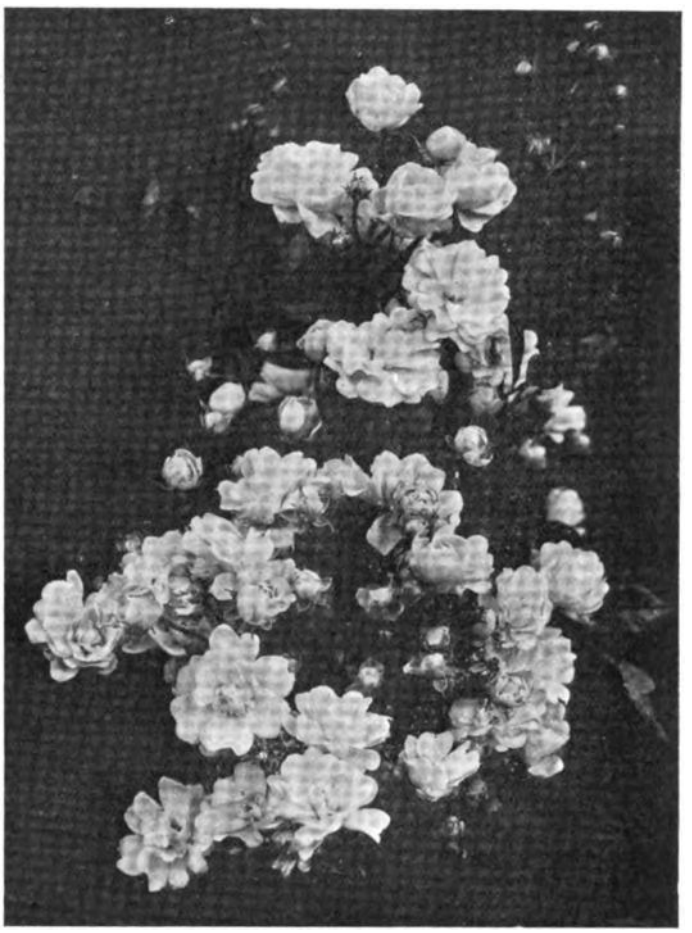
POLYANTHA POMPON ROSES

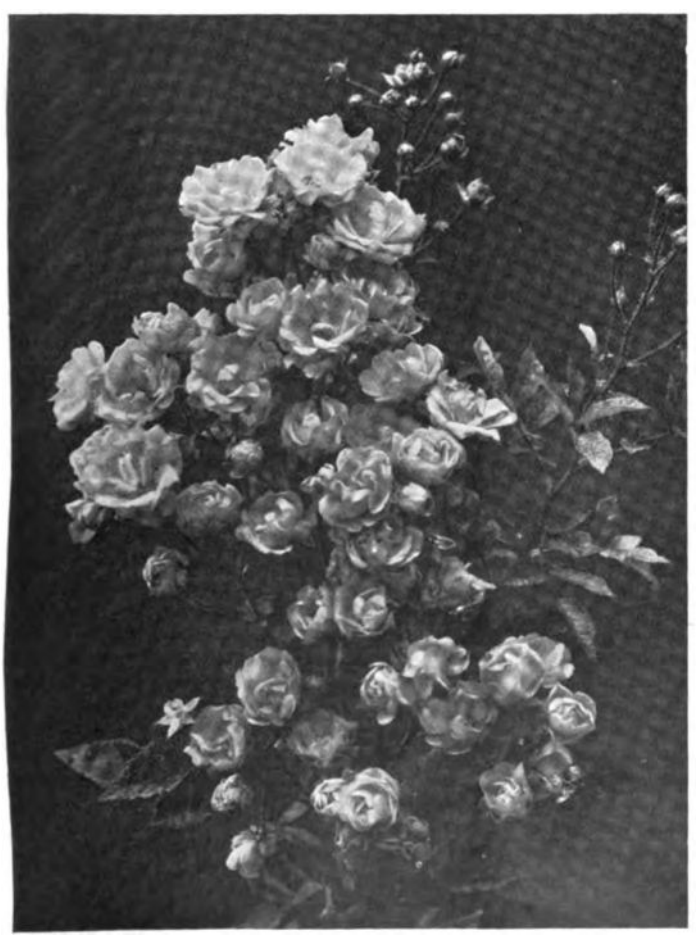
FOR THOSE WHO HAVE SMALL BEDS ON THEIR LAWNS AND WHO WISH TO FURNISH THEM WITH SOMETHING PERMANENT, THE DWARF POLYANTHAS ARE ALMOST IDEAL.

THE above is the correct name for the dwarf as distinct from the climbing polyanthas. The word "polyantha," as everyone knows, is derived from the Greek: it means "many flowered," therefore all the roses in this class, whether climbing or dwarf, are grouped under the heading Rosa multiflora. The type is a summer-flowering climber; but the polyantha pompons, or "poly poms," to use their pet name, are hybrids and of a dwarf compact habit. The flowers individually are very small, they are in most cases produced in clusters on straight upright stems, and they flower with great freedom throughout the season—in this respect altogether surpassing the climbing varieties. Some, like Katharine Zeimet, bloom, as it were, in bursts, a great show of blossom followed by an interval before they flower again; while others, and the majority may claim to belong to this second category, are practically never out of bloom from June to November. For those who have small beds on their lawns such as might have been used for the now old-fashioned bedding plants, and who wish to furnish them with something permanent, the dwarf polyanthas are almost ideal.

In our garden we have a grass plateau near the house with a gentle tilt to the south, in which we have made a "baker's half-dozen" of round beds, and have planted each with one variety of dwarf polyantha rose. We have surrounded them with an edging of violas, being careful to choose a colour which will harmonise with the rose. The mauve Maggie Mott or the lavender Kitty Bell look very well round Katharine Zeimet and Little Meg, or any other white or pale pink rose; but the crimsons, such as Triomphe d'Orleanaise and Koster's Orleans, look far better if planted with a white viola—White Swan or the miniature Will Taylor are suitable varieties. Contrary to the advice of many eminent rose growers, we plant daffodils



CORAL CLUSTER IS A LOVELY SHADE OF PALE CORAL.



THE ROSE-COLOURED ORLEANS.

or tulips in these beds, and therefore get a succession of bloom throughout the spring, summer and autumn.

To do this successfully the beds must be well made and well tended. We are on a gravel soil, so we have to dig out our beds and borders to a depth of 2ft. 6ins. or 3ft. and fill in with good top spit mixed with manure and the siftings of the gravel—towards the top we put a sprinkling of ½in. bones.

The roses must be carefully and firmly planted in the autumn, they must be kept hoed and weeded throughout the summer, and after the first season they will benefit much by an occasional thorough soaking with weak liquid manure. The first season they should not require, and indeed are better without, this; but if the weather should be very dry they will be grateful for some applications of clear water, provided that whoever cares for them remembers that the hoe is a much better servant than the watering pot. Two inches of constantly stirred soil provides a mulch which conserves the moisture rising from below and tends to keep a far more uniformly moist condition for the roots than spasmodic waterings with probably hard water from above; when watering is of necessity resorted to, let it be thorough and see that it is always followed by a vigorous use of the hoe.

The spring after planting, the roses should be pruned hard. If they are to be used in beds on the lawn or as borders to other roses this hard pruning should be repeated each spring: it makes the flowering a little later, but it ensures a dwarf and stocky growth which is essential for bedding roses.

These polyantha pompons will also make delightful specimen bushes if, after the first season, they are only lightly pruned and thinned. The now old-fashioned Perle d'Or, with its

exquisitely shaped nankeen yellow buds, appreciates this treatment, as does the newer Yvonne Rabier, which throws up large clusters of pure white fragrant blossoms when left to grow according to its own sweet will.

However, there is no doubt that the " poly pom's " greatest use is as a bedding plant, and probably readers may like a short account of some of the best varieties for this purpose.

WHITES.

Katharine Zeimet has an excellent habit. It flowers profusely and frequently, but not quite continuously. It is one of the earliest in bloom, and has what, unfortunately, is a rare quality among these polyantha pompons, a sweet fragrance. It is not a good rose for picking, the petals fall quickly and, being of papery texture, they easily " brown " in wet weather.

Little Meg is quite a different type, but is almost equally good for beds. The habit is more diffuse; this, however, is compensated for by the beauty of the shining dark green foliage. The flowers are produced in thin sprays rather than in clusters; they are of firm texture and of exquisite shape, milky white, the buds sometimes tipped with crimson. This variety continues flowering right on into November. The shining foliage would suggest that it is a hybrid with the dwarf wichuraianas. Altogether a very charming little rose and one of the best for small vases. Those who require an extra dwarf white variety should grow

Jeanne d'Arc, with clusters of small white well shaped flowers which have a certain fragrance.

YELLOWS.

I know of no good yellow among the poly poms. *George Elgar* has pretty yellow buds, but they are not freely produced and they turn a dull white when open.

Coronet is a pretty little creamy yellow variety, but the tints of peach and coral on its petals really put it out of a class for pure yellows. Will not someone raise for us a dwarf polyantha with blooms of the brilliant golden yellow we have among the Pernetianas?

PINKS AND ROSES.

There are now several good pink and rose varieties in the class we are considering, but I do not think that *Mrs. W. H. Cutbush* has been beaten in prettiness of colour, a clear pink, freedom of bloom and dwarfness of habit. From our experience of it on a light soil, I should say it requires good soil and cultivation.

Maman Turbat has larger flowers also of a bright pink, but the clusters are not so erect nor the blooms so pretty as those of Mrs. Cutbush.

Orleans and *Ellen Poulsen* are two splendid rose-coloured varieties, Orleans the more vigorous of the two and with larger trusses; Ellen Poulsen has flowers of a prettier shade and shape which are decidedly fragrant. This is one of the best of all the polyanthas. It makes a good standard.

Coral Cluster and *Princess Juliana*, in suitable weather and especially under glass, are a lovely shade of pale coral. In hot weather they are apt to lose their prettiness of tint.

Perle Orleanaise is a very dwarf variety with soft salmon-rose flowers produced in clusters; it deserves to be more grown than appears to be the case at present.

CRIMSONS.

We now have several crimson varieties. The old favourite, Jessie, is almost superseded by such vigorous yet dwarf varieties as *Triomphe d'Orleanaise* with very large trusses of light crimson flowers. This variety is wonderfully free and continuous. I have a bed of it under the drawing-room window, and throughout the season it is gay and cheerful.

Koster's Orleans is of more upright habit and has, I think, brighter flowers; but *Edith Cavell* is, so far, my favourite among the crimson poly poms. It has big trusses of really dark crimson flowers which never turn blue; in hot weather they are apt to burn, but in a cool summer and in the autumn the colour is wonderfully fine.

At the Chelsea Show last May, Messrs. Frank Cant were exhibiting a variety called *Reine Elizabeth*, which, as shown on that occasion, was even more brilliant than Koster's Orleans or Edith Cavell, and I felt it was one to be added to our collection this autumn if it proves as effective out of doors as under glass.

A delightful little crimson poly pom is *Eblouissant*, which I have left to the last because it many ways it seems to me to resemble a China rather than a polyantha. It has small dark green foliage, good upright trusses of blood-red flowers which neither " burn " nor " blue," and its habit is so dwarf that it is really suitable for rock gardens or for an edging; it should not be planted among strong-growing kinds.

All these poly poms are wonderfully hardy; it is rare, indeed, to lose a plant; but, like all other flowers, if they are worth growing at all they are worth growing well, and, if given good soil and a certain amount of after care, they will reward their cultivators by giving thousands of bright and pleasing blossoms all the summer through. WHITE LADY.

SUMMER-FLOWERING HARDY HEATHS

SINCE it is our native species which constitute by far the greater portion of the cultivated heaths, it seems only just that some reference should be made to them at this their flowering season, which latter will extend without a break well into autumn.

For some reason difficult to assign heaths have never been popular garden plants, yet the same thing in the wild state makes a stronger appeal to people generally than almost any other wild flower. But there has been a steady increase in the planting of hardy heathers during the last few years, and the nurseryman, recognising this fact, has not been slow to offer new varieties, which are for the most part collected forms or the results of hybridisation.

That the hardy ericas should lately have enjoyed a revival of interest is, perhaps, what one might have expected; for, in the first instance, there are few plants which lend themselves so admirably to those many phases of modern gardening which present a reaction from the formal and which, in some cases, have become the very antithesis of the latter. Further, the rock gardener has discovered in these shrubs an invaluable material for the adornment of his creations, and one that will most effectually afford them just that touch of the natural to which he usually aspires. I might, indeed, pursue the subject still farther and suggest, as not a few have actually demonstrated in practice, that a plantation of heaths stands second to none as a go-between that will constitute an harmonious link between the rock garden and other parts of one's domain.

Yet, when all is said, it is not as an adjunct to something else that the heath garden deserves the highest note of praise. It is its own singular beauty and natural charm and the long season of gorgeous colour and fragrance which it affords with a minimum of attention that must always be its most telling recommendations. As a matter of fact, if we bring in a few species other than our own, the heath garden need never be without masses of colour at any time of year, and that, I think, is a claim that can scarcely be made for any other race of hardy plants in cultivation.

Heaths are, moreover, most adaptable, and easily grown on practically any lime-free soil which is well drained Indeed, several of them are accommodating enough to show none of that dislike for lime which is common to the ericaceæ generally. Not one of them needs peat and, despite the popular belief that they are difficult to establish, they are, under average conditions and with reasonable care, as amenable to transplanting as any other evergreen and much more easy than some.

A few years ago we planted with heathers a steep, hot, southern slope of poor, shaley soil which had never grown anything better than a few scrubby gorse bushes. To-day the whole of the area is completely covered, and I do not think any part of the garden affords as full a measure of satisfaction as this does. Certainly none asks for so little labour. Once the ground gets covered the most prolonged drought is defied, and, unlike many other shrubs (rhododendrons, for example), the vitality of the heaths is so amazing that they never fail to flower with the greatest prolificacy every succeeding year.

In dealing with the dwarf ericas (including calluna) I cannot do better

Digitized by Google

than refer to some of the more outstanding species and varieties, and I may say that none of the kinds mentioned here has had any peat. A little leaf-mould about the roots when put in, deep planting and, in some instances, a light covering of bracken or other litter during their first summer should the season be very dry, is all they have ever had, and our losses have not amounted to five per cent.

E. cinerea opens the season of these natives, and this species has proved the most successful for the driest and hottest parts of our slopes. E. c. rosea is, perhaps, the finest variety, a strong grower with immense heads of flower from June onwards, in a full-toned rosy crimson quite devoid of that hint of blue which so often prevails in the blossoms of the wild type. Plants of this not infrequently throw seedlings of an equally good and sometimes even richer colour. Another good one is atropurpurea, rather dwarfer than the above; and then there is that wonderful little variety, coccinea, not more than about 6ins. high, with dark green, bronzy foliage and blooms of an intense blood red which has a sufficient dash of scarlet in it to render it distinct in colour from all others. Among the newer cinereas on their trial here, those which give most promise are the pink and white Apple Blossom, a clear, wild rose pink form, and another with flowers of a vivid cerise. The white cinerea, of which there is a dwarf form, is well worth a place, but it does not seem to be so indifferent to poverty as the rest, and generously repays one for a rather cooler soil.

Before the above are in full colour those of the calluna group enter the field. Here the pretty crimson tenuis is usually the first to adorn its slender spikes, soon to be overtaken by the double form of our common heath, which is unsurpassed in its own colour for massing in large or small groups. The soft lilac flush produced by multitudes of the perfectly double flowers which last for months is very charming, especially in subdued light. The variety Alportii, with very dark green foliage and deep crimson flowers, is still, perhaps, the best of its colour in this class. Though later than the white form of the type—the popular White Heather—Serlei is much superior to this in stature, making a superb bush, sometimes up to 3ft. in height, with elegant, branching sprays which bear pure white flowers in the utmost profusion. Hammondii, hardly so tall and rather more stiff and erect, is another white worth a place among the best, and the foliage of both of these is at flowering time a remarkably fresh and pleasing green. Yet another first-rate white in this section, quite distinct with its numerous very slender growths and finely tapered, sinuous spikes of dead white flowers, is gracilis, hardly to be distinguished from the elegant tenella.

ERICA VAGANS ALBA, THE WHITE CORNISH HEATH.

The blooming of the cross-leaved heaths (E. Tetralix) is contemporary with the callunas and continues practically all summer and early autumn. Of this set the grey-foliaged mollis, with large bells of a clear white, and an improved form of the rosy-coloured type species are still, to my eye, the most attractive, but there are some new rosy-purple and deep red varieties which will doubtless make their mark when better known. The cross-leaved heaths all need rather better living than the above, but they may, nevertheless, be grown to perfection in any fairly light loam that does not dry out too quickly in summer. This also applies to the hybrids raised from Tetralix, as well as to the lovely Dorset heath (E. ciliaris) the finest of all our natives and, curiously enough, perhaps the least known.

Even larger in blossom and of stiffer habit is the form of ciliaris known as E. Maweana; and then there is the superb E. Watsoni, which possesses all the best and most outstanding features of its two parents, ciliaris and Tetralix. A new hybrid of the same parentage and called E. hybrida Dawn is very beautiful and distinct. E. Williamsii, supposed to be a Tetralix × vagans hybrid, and discovered wild in Cornwall, produces in the later summer umbels of rose-crimson bells.

E. Mackayi, supposed to be a form of Tetralix, but with a more trailing and looser habit of growth, is a pretty variety in the mass, with its rosy bells, and it is preferable, in my estimation, to the double form, the flowers of which suffer from congestion. E. Stuartii, supposed to be a hybrid between the above and E. mediterranea, is a very cheerful-looking shrublet the pale shell-pink flowers of which are conspicuously tipped with carmine. E. vagans also claims attention as the most useful of all the autumn-flowering kinds, and it presents varieties in a wide choice of colour from white and cream to pale pink and deep crimson. But the Cornish heath attains its greatest perfection in St. Keverne, a beautiful variety with immense heads of bright crimson flowers, a fine deep-green foliage and good habit. A. T. JOHNSON.

THE EDITOR'S TABLE

WE have received a box of beautiful herbaceous peonies from Messrs. Kelway and Sons of Langport, Somerset. The glorious coloured fragrant blooms poised on stiff stout stems makes one wonder why these beautiful plants are not more generally grown. The foliage, too, is very elegant. Among the blooms so kindly sent are Lady Pocock, a double-flowered white variety with narrow central petals; Captain Cheape, a double-flowered variety with soft pink guard petals, pink and cream central petals; Mrs. E. Dunkels, lavender pink, loose double-flowered variety; Kelway's Success, a double-flowered sort with pink guard petals and rich cream central petals; Alice Balfour, a double-flowered rose variety; Rosemary, rosy pink guard petals, with lighter central petals, spicy fragrance; Mrs. E. Balfour, rose guard petals, central petals cream flushed pink; Limosel, deep rose with rose scent, a very fine double-flowered sort; T. J. Lipton, maroon; Mrs. Lutwych, white guard petals suffused pink, pale yellow central petals; Austen Chamberlain, a single-flowered sort of bright crimson colour, with conspicuous golden anthers; Wilbur Wright, another single-flowered kind of deep maroon colouring, also having conspicuous golden anthers. These peonies are excellent for cutting purposes and are ideal under artificial light.

WISLEY GARDENS

BY E. H. M. COX.

MY visit to Wisley was made on one of those days, only too rare, which Victorian novelists used to describe with such abandon. Their descriptions usually began with such euphemisms as " 'Twas on a warm summer day in June when the bees were winging their way to steal the scented nectar from the flowers . . ." At any rate, the day was warm, and showed up all the many beauties of the garden.

The work carried on at Wisley is unending in its ramifications. There are the laboratories in which diseases are examined and their prevention and cure worked out; there are fruit-testing grounds, and rose-testing grounds, peony trials, helianthemum trials, lettuce trials, where the best varieties are chosen from among hundreds and names are checked and rectified; there are hot-houses filled with tomatoes and fruit where the students are trained in fruit culture; then there are the main gardens, where flowers and trees and shrubs are grown. It is the main garden which is of the greatest interest to most Fellows of the Society.

THERE ARE WOODS CARPETED WITH PRIMULAS—

AND WILD BORDERS FILLED WITH LUPINS.

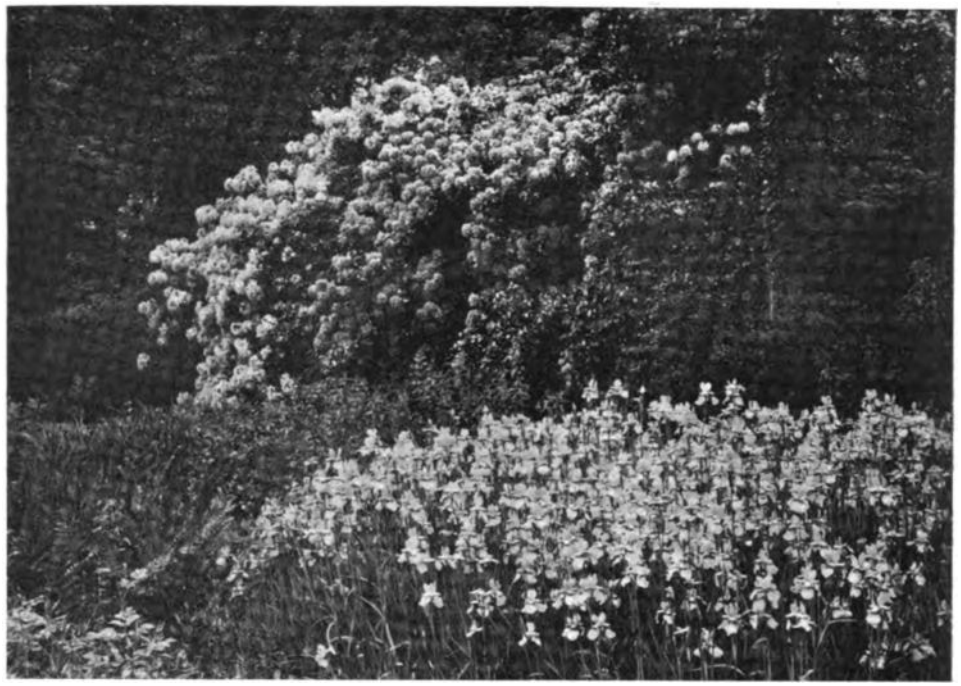
Wisley was the munificent gift of the late Sir Thomas Hanbury, who presented it to the Society in 1904. It had formerly been in the possession of the late Mr. G. F. Wilson, who had formed a famous wild garden there which is still in existence. This is still probably the most attractive part of the garden, for the situation is perfect. There are ditches and pools with irises alongside and water lilies flourishing in them, there is a wood divided into sections by great banks of old hybrid rhododendrons and other evergreen trees and shrubs. In these bays flourish heaths and lilies and shrubs. Lilium giganteum, one of the prides of the garden, is exceedingly vigorous, and L. rubellum was in full flower. The heaths are inclined to be a little straggly, and these bays are so valuable for growing shrubs which require shelter that the heaths might well be removed to some more exposed part of the garden. The same thing might be said of the Siberian irises, which are too plentiful. They are among the most accommodating of all plants regarding soil and climate. With the knowledge and skill of those in charge of Wisley at their disposal, many Fellows would be glad to see the area devoted to Siberian irises cut down and other plants grown in their place, perhaps just as beautiful, and about the successful cultivation of which something could be learnt.

One of the most interesting sights at Wisley at the time of my visit was the trial of helianthemums. The variations and brilliant colouring of the different strains are amazing. Two of the most effective are Ben Nevis, yellow with an ochre eye, and Nicoll No. 16, white with an orange eye. Both of these plants have been raised by Mr. Nicoll in Forfarshire. It is in a trial of this kind that the usefulness of Wisley to all Fellows of the R.H.S. is, perhaps, most apparent. Helianthemums are becoming more and more popular every year. In a long row at Wisley can be seen all the best varieties. Personal choice can be made and personal preferences decided upon for future use.

Close by the helianthemum trials is the alpine house, which is now passed but shows the excellence of cultivation which is usually to be found at Wisley. The one exception to this general excellence is the rock garden, in which I was profoundly disappointed. There is probably no rock garden in the country which is so well designed and has such infinite possibilities. There are moraines and bogs, dry banks and

Digitized by Google

innumerable sheltered nooks and crannies. There are two slopes in the middle, in which the gradient is a trifle too slight, but I was told that this portion is going to be remade during the coming winter. However, this is beside the point. I have heard many Fellows say that the cultivation of the rock garden is not up to the usual excellence to be seen at Wisley, and this is only too true. The choicer clefts and crannies are filled with common plants and weeds—I even saw a big patch of the common white campion, a terror for seeding itself; the bogs are filled with Primula japonica when there are dozens of newer and better species and hybrids which could be grown and which would show members how they should be grown; fine flats are filled with creeping thymes—a little of it is excellent, but there is no necessity for square yards, spreading at its will. There might also be a special bank set aside for cistuses, instead of filling up valuable space with full-sized plants. Apart from this, the cultivation of most of the plants that are to be seen in the rock garden is not up to the standard of dozens of private rock gardens.



SIBERIAN IRISES IN A LOVELY SETTING.

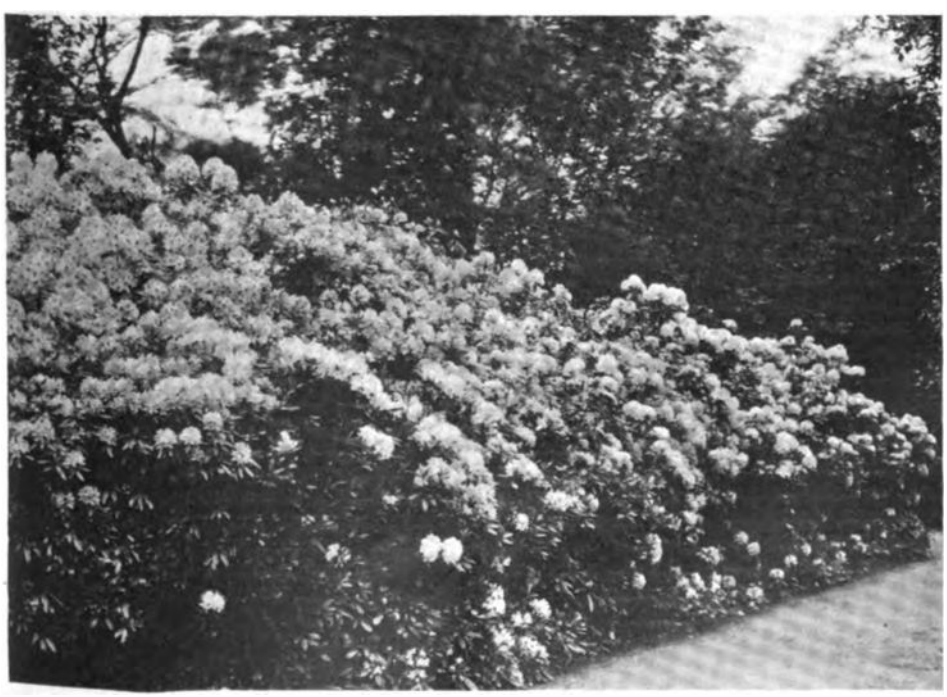
When comparison is made between the rock garden and the collection of shrubs the difference in cultivation is noticeable, but then the shrub garden is new while the rock garden as an old established entity has probably not had sufficient time to recover from its war time experiences. However, the years are passing, and many Fellows will not realise the extraordinary difficulty under which Wisley was kept up during the war. Perhaps the Wisley Committee could arrange for fewer vegetable trials, and with a certain amount of money saved give the rock garden a thorough spring cleaning.

Not only is the collection of shrubs varied and interesting, but they are cultivated at a very high level. Here are loniceras, cotoneasters, buddleias (including Farrer's excellent B. alternifolia in full flower), hypericums, and so on. They are a credit to any garden, and with the exception of the new heath garden mentioned in the Editorial article the lay-out of the ground could not be bettered. Another interesting collection is that of rose species, and members would be well advised not to miss this most instructive collection.

In one of the houses was a most interesting collection of South African annuals, being grown, I believe, for the South African Government. They were all composites, and among them were Charieis heterophylla of a heavenly blue colour; Dimorphotheca pluvialis, a particularly handsome flower with white rays and a violet centre; and Aster Bergerianus, another fine blue. None of these plants is in general cultivation, but they are well worth growing, either in a cool house or grown on in a house for bedding outside.

Altogether, Wisley is a garden of great beauty and is of interest to all Fellows of the Royal Horticultural Society, they on their part should interest themselves in the garden, by visiting it and seeing all its ramifications and also by giving specimen plants to add to the collections in the garden.

After all, although Wisley has been organised to help Fellows of the Royal Horticultural Society, yet it is obvious that for its well-being there must be a little give and take. Every Fellow should try and visit it as often as possible.



A FINE BANK OF OLD RHODODENDRON HYBRIDS.

OUR NEXT ISSUE IS PARTLY DEVOTED TO IRISES. AMONG THE ARTICLES WILL BE:

GROWING IRISES FROM SEED, by Sir Arthur Hort, Bart.

IRISES FOR EVERY GARDEN, by A. J. Bliss.

THE SUCCESSFUL CULTIVATION OF IRISES, by W. R. Dykes.

A DISCOURSE ON NYMPHÆAS—II, by F. Laplace.

NOTES ON A CHALK GARDEN, by F. E. Stern.

REPORT OF THE ROYAL HORTICULTURAL SOCIETY'S SHOW.

Digitized by Google

VEGETABLES AS A SEPARATE COURSE

A GREAT deal might be written on the excellent subject of separate vegetable courses. These are particularly palatable during the summer months when meat is sometimes not so appetising as it might be. On the other hand it is a mistake to imagine that vegetable cookery, owing to its simplicity, requires little attention. In its very simplicity one is inclined to let the fragrance of the vegetables escape owing to slip-shod methods. There is one kind of utensil which is almost a necessity in the preparation of vegetable dishes and that is those made of brown, unglazed fireproof earthenware, whether saucepan shaped or such as are used for oven cookery. Utensils made of pottery seem to retain the flavour better than those made of metal. They are also useful in that slow, measured cooking which is so necessary in most vegetables.

1. PETIT POIS A LA FRANÇAISE (Peas à la Française).—Take eight small button onions and one lettuce and cut them in small squares. Mix them with one pint of shelled peas and wash them. Melt ¼lb. of butter in an earthenware pan on a slow fire; add the vegetables, a little salt, and two tablespoonfuls of castor sugar. Cook them together for twenty-five minutes, stirring the mixture fairly regularly. The secret of this dish is in the slow cooking.

2. CHOUX FARCIS (Stuffed Cabbage).—Take a large white cabbage and wash it carefully. Place it in a saucepan of cold salted water and cook it until you can remove the leaves without breaking. Then strain it and pick off the leaves one by one and dry them flat on a cloth. Cut up one large onion in small pieces, together with a few mushrooms and two tomatoes. Cook the onion, mushrooms and tomatoes in an earthenware pan with ¼lb. of butter. When the mixture is thoroughly cooked add a teacupful of ready cooked rice, salt and pepper to taste, a bunch of herbs, and a pint of consommé or chicken broth. Cover it with a sheet of buttered paper and cook it in an oven for twenty minutes. When ready add another ¼lb. of butter and mix well. Then take a tablespoonful of the mixture and laying it on the centre of a cabbage leaf, roll the leaf around it. Squeeze the rolls one by one in a clean cloth to remove excess of moisture. The next step is to cut one carrot and one onion in slices and place them in a stewpan with butter and a little consommé. Place the stuffed cabbage leaves in the stewpan and cover it with a sheet of buttered paper. Let it cook slowly in the oven until the carrot and onion slices are soft and the liquid is reduced. This is an exceedingly popular method of stuffing vegetables on the Continent. Lettuces, tomatoes, artichokes and egg plant may be treated in the same way, tomatoes are improved by cutting a hole in the top an hour before cooking and pouring in a teaspoonful of port wine. The method may sound a little complicated, but it is well worth the trouble, for the flavours of the different vegetables are preserved and the result is a most appetising dish.

3. CHOUXFLEURS POLONAISE (Cauliflower Polonaise).—Cut a cauliflower in pieces and cook in salted water until they are tender but not too soft. Then place them in cold water. Brown 2oz. of butter in a pan and when browned heat the cauliflower pieces in it with salt and pepper. For the sauce you take one hard-boiled egg and chop up the yoke and the white separately. Mix with bread crumbs and chopped parsley; then place the mixture in a pan with ¼lb. of melted butter and mix well. Place the cauliflower in a shallow earthenware dish and press the pieces closely together. Just before serving pour the Polonaise sauce over it.

Asparagus may be cooked in the same way, and is an extremely succulent dish.

4. ARTICHAUTS A L'ITALIENNE.—Take some artichokes, remove the leaves and the beard, and carefully trim and clean the bottom. Place them in cold salted water and cook thoroughly; then dry them thoroughly in a cloth. Cook slowly together ½ pint of consommé, a small onion, ½oz. of butter and a sprig of tarragon, then add a little white wine, taking care to stir the mixture all the time. Let the liquid reduce a little, then arrange the artichokes in a flat earthenware pan and pour the sauce over them. Sprinkle breadcrumbs mixed with a spoonful of grated gruyère cheese over them, and brown in the oven.

5. SPINACH WITH VARIOUS DRESSINGS.—Pluck the leaves from the stems of spinach. Wash the spinach carefully, shake it dry; throw it into a saucepan of boiling water for five minutes; remove it and throw it into cold water; press all the water out of it, hash it, pass it through a sieve; put it into a saucepan with 2oz. of fresh butter, salt and pepper; after five minutes it will be cooked. Have ready the yolk of a fresh egg with which you have incorporated 2 dessertspoonfuls of fresh thick cream; mix with the spinach. Now dish up the spinach with a garniture of fried crusts of bread, or with eggs poached in a poacher, or with hard-boiled eggs cut in half. Instead of the yolk of egg and cream, a good clear gravy or meat juice may be used; in this case garnish with fried ham, or braised ham, or tiny sausages, or with poached eggs. For six persons, 4lb. of spinach if the leaves are young, 3lb. if mature. Plenty of salt and pepper is required for this dish.

6. SUBRICS OF SPINACH.—After having blanched, refreshed, pressed and chopped 2lb. of spinach, throw it into hot butter. Salt and pepper, and add a tablespoonful of flour. Let this purée cook for six or seven minutes, then take it off and add three eggs thoroughly beaten. Mix them slowly with the spinach, and, spoonful by spoonful, drop them into a stewpan containing sufficient quantity of steaming butter to fry them. Turn the subrics from one side to the other and let them cook for another three or four minutes; strain and serve them in a turban on a round dish with a good creamy béchamel sauce in the centre.

7. CHOUXFLEURS AU GRATIN (Cauliflower).—Cut the flowers with their stalks from a large cauliflower. (Select it "close" and not too full blown.) Throw them into a basin full of water with a little salt, to kill any insect that may be hidden. Put sufficient water into a saucepan, with a handful of salt, to cover the flowers. When the water boils put the cauliflowers into it and cook until tender. Drain through a strainer and place each piece of flower, stalk upwards, into an ordinary pudding basin, fill the basin, always with the heads of flower downwards, until all the cauliflower is in it, the loose pieces at the last. Press them a little and turn them out on a dish. Throw a béchamel sauce over the cauliflower (that should now have its original shape), grate a little gruyère or parmesan cheese over it, and put into the oven for a few minutes.

The sauce is made with a lump of butter in a small saucepan, a tablespoonful and a half of flour, salt and pepper, mix one with the other and add half a pint of hot milk, turning the sauce for about ten minutes while it boils and becomes as thick as cream.

These few recipes may be of some assistance to our readers in showing how vegetables can become the central dish of a light meal. In an early issue salads will be dealt with.

THE LIFTING AND STORING OF BULBS

BY W. R. DYKES.

TOO many gardeners bulbs are things to be ordered from a catalogue, planted in the autumn to make a display in spring and then, when they have flowered, to be dug up and either thrown away or left lying about. Another alternative is to cut off the leaves of the bulbs when the flowers are over and to plant over the bulbs annuals or bedding plants. Then in the following year when the bulbs throw up a few weak leaves and no flowers, the excuse given is that they are no good after the first year.

The truth, however, is that most bulbs, when grown in suitable soil, increase rapidly and flower regularly year after year. It is many years ago now since I bought my first tulip bulbs and I remember that ten bulbs of the variety Inglescombe Pink were among them. With careful treatment these increased so rapidly that after a few years I always had as many flowering bulbs as I could find room for and was able in addition to give away several hundred every year.

In dealing with bulbs one thing must always be remembered, and that is that the bulb which is planted exhausts itself in the effort of flowering and that a new bulb has to be formed for the following year. This new bulb can only be built up with the help of the moisture and nourishment which the growing plant extracts from the soil and which is transformed from its crude form into food by the action of light on the green chlorophyll contained in the leaves. Obviously, therefore, nothing must be done to disturb the plant so long as the leaves remain green and continue their function of preparing food for the bulb that is maturing for the following year. Until the leaves are mature and begin to turn yellow, the bulbs should be left undisturbed or, if they must be moved, the operation should be carried out with as little disturbance to the plants and their roots as possible and they should on no account be allowed to become dry, but be replanted and watered in with as little delay as possible.

Another most important point which many seem to overlook in dealing with bulbs is that there are several very different kinds of bulbs and that they vary very much in their behaviour. Some bulbs, like those of tulips and Spanish irises, lose all their roots for a period of some weeks in summer, while others, like those of lilies and Narcissus Poeticus, are practically never rootless. From these differences we can draw useful inferences. Bulbs, which lose all their roots, come from regions where the soil is baked dry and becomes hot for a considerable depth during the long drought of summer. To grow these bulbs successfully we must provide a resting period during which the bulbs must be kept warm and dry, whereas lilies, which delight in a cool, moist soil and which are never rootless, should never be kept long out of the ground and are often difficult to establish if, as in the case of the bulbs imported from Japan, all the main roots are cut off when they are dug up.

Bulbs, which during the resting period in summer lose all their roots, may be moved with impunity every year and, in fact, flower all the better for an annual change of soil. The roots of bulbs are not usually very long and therefore, if the bulbs remain undisturbed, they have to push out into the same soil which nourished their predecessors of the previous years. The result is weaker growth than when the bulbs are moved annually and this is probably the reason why many bulbs, which when cultivated in our gardens increase rapidly by offsets, never in the wild state produce any offsets at all, but flower year after year in the same spot, set seeds, and then die when they have exhausted the soil within reach of their roots.

When bulbs are dug up, they should be allowed to dry for a few days in a cool, airy place, but not in the sun, as is sometimes recommended. Exposure to the sun usually splits the skins of bulbs and tends to cause them to shrivel. When the bulbs are thoroughly dry, they should be cleaned and have their old skins removed. Then they may be stored in boxes or paper bags in a warm, dry place. Crocuses, irises and especially tulips seem to benefit when they are stored in a temperature between 70° and 80° Fahrenheit. Under such conditions they remain dormant longer, but crocuses should be replanted in July and August, irises in October and tulips in November. Narcissi, muscari, fritillarias, snowdrops and chionodoxas derive no benefit from being kept out of the ground, though I am inclined to believe that the Crown Imperial, Fritillaria Imperialis, flowers best when it is lifted annually and replanted after about a month. In every case a sharp look-out must be kept for signs of new growth and the bulbs replanted immediately they appear. While bulbs are out of the ground, they should be kept covered or in closed bags in order to keep off attacks of fly and it is as well to put pieces of naphthalene among the packages for the same purpose.

MR. MILLAIS' NEW BOOK ON RHODODENDRONS

IN rhododendrons and their various hybrids, Second Series (Longmans, Green and Co., 1924, folio, £10 10s. net), Mr. J. G. Millais has carried his labours on the genus rhododendron a step farther. This second series is in every way a worthy successor to his first book on the subject, pubished in 1917.

With the tremendous flow of new species and hybrids into cultivation, it is not, perhaps, so amazing as many people will imagine for a new folio of 265 pages to be written within seven years of the first volume, with entirely new material and little repetition. This influx of new rhododendrons is partly due to the activities of botanical collectors such as George Forrest and F. Kingdon Ward, and partly owing to the recent crosses made by hybridisers, both English and Dutch.

In the first chapter of this new volume Mr. Millais explains the reason for the increase in the popularity of shrubs in general. He says that the pre-war idea of extravagant gardening has disappeared and that the requirements of a present-day gardener are "Smaller lawns, few rose-beds and herbaceous borders, economic and non-weedy paths, less manure, fewer greenhouses, no bedding-out in autumn, fewer beds for annuals, and more space devoted to beds and woodland walks of flowering shrubs." There is little doubt that rhododendrons are among the most satisfactory of all flowering shrubs. Owing to the introduction of such late-flowering species as R. decorum, a new race of late-flowering hybrids is springing up which will prolong the flowering season until well on in the summer, and this removes one of the main arguments against the use of rhododendrons. He then goes on to give notes and extracts from letters of the different collectors in China. These are of the greatest importance, because it is by trying to duplicate their native conditions that we have the greatest chance of success with many of the new species. Unfortunately, many species are slow to flower, and this is, of course, where hybrids have an advantage; but by giving them conditions akin to what they are accustomed to in the wild state, this disadvantage may often be overcome.

In this volume Mr. Millais mentions all new species and named hybrids described or introduced since his last volume. In addition, he gives valuable notes on many of the older plants whose idiosyncrasies have become better known during the past seven years. Whether gardeners in the future will always agree with Mr. Millais' conclusions remains to be seen, for it is often difficult to give judgment on a plant during the first year or two of flowering. It may not have quite got into its swing, and so the colour and shape may improve as the years pass. However, that is one of the difficulties which all who write upon rhododendrons have to face.

Although the price of this volume and the difficulties in obtaining many of the plants mentioned may keep some people from buying it, yet its value to the enthusiast is inestimable. It is a book which he must possess, and, if a word of advice may be given, it is a book which should be in every public library in districts in which rhododendrons will

Digitized by Google

grow. In that way many gardeners who might otherwise never have a chance of referring to it may be able to use it as a work of reference. Unlike works on most genera, Mr. Millais' two volumes supply a complete compendium on rhododendrons.

The production of the volume is excellent, and particular mention must be made of the brilliance of the collotype plates. The author has gone to an immense amount of trouble in collecting photographs of rhododendrons growing both in this country and also in their native habitat.

There is little doubt that woodland gardening, in which rhododendrons play such a large part, is becoming more and more popular every year. If the ground is suitably prepared to begin with, they require little attention apart from an annual mulching and watering in times of drought.

It is lack of sufficient preliminary preparation that is most often responsible for failures, that and ignorance of their requirements. Our rhododendron knowledge is rapidly advancing, and a great deal of this knowledge is due to Mr. Millais' efforts.

CORRESPONDENCE

CATALOGUES.

SIR,—In these cosmopolitan days—when gardeners from the Antipodes vie with European raisers of roses and shrubs from strange lands, and the notes in THE GARDEN are eagerly read in the Colonies and on the Riviera—it is a pleasure to read the catalogue of the firm of Hazlewood Brothers, who garden at Epping in New South Wales. A kind friend gave it to me the other day, and I find it is more careful and correct in its notes on the new roses and other plants that are offered than any European catalogue that it has been my fortune or fate to study: so much so that I hope it may be read and studied by the compilers of catalogues in Europe.

Among the excellent rose notes I read that the white rose, Louise Crette, a seedling of Frau Karl Druschki and Kaiserin Victoria, is mentioned as very distinct but a bad opener in wet weather. I have seen no mention of it in English rose shows, so I imagine it is not a success in English gardens. This spring there was a burst of excessive heat in May on the Riviera, and plants of this rose produced such wonderful double blooms, so magnificent in size, shape and lasting powers, that it far surpassed its parents. Under glass or in hot seasons, it should be worth a trial, for one huge and very double bloom cut with a long stem lasted eleven days in water before it faded, and was the admiration of all who saw it. My Australian friend tells me it is even better in autumn and winter, when the blooms are not so excessively double or quite so enormous; so I hope gardeners in the Riviera will try it both under glass and in the open. The hybrids of Rosa gigantea seem to open out a new vista of early spring roses that sounds most inviting—in fact, there is *much* we can learn from our friends in the Antipodes and, as I hear, from the Californian coast also: but as yet I fear there is no other catalogue so careful or moderate in its description of plants offered for sale.—E. H. WOODALL.

THE PROPAGATION OF CHOISYA TERNATA.

SIR,—It is difficult to understand how it is that so many correspondents appear to find Choisya ternata a troublesome shrub to strike. Even assuming that the cuttings are somewhat fastidious in a cold frame (which is certainly not a general experience), no shrub is more easily layered than this one. Any branches that come in contact with the soil will root quickly and well, and in addition to these there will generally be a number of suckers which can be pulled out with roots attached. Then why all this controversy?

Some gardeners really seem to go out of their way to do things in the most difficult manner they can conceive. There is Romneya Coulteri, for example. We are told that you can only propagate this plant successfully from root-cuttings, which means digging up an established clump, bottom heat, and no end of fuss. Yet, by pulling up some of the suckers which R. Coulteri produces only too liberally—and they have got to be pulled up anyway—you will find a goodly proportion of these will have sufficient root attached to them to enable you to plant them out direct into the open ground. I have now a nice little stock of plants all raised in this way.—A. T. JOHNSON.

GENTIANA VERNA.

SIR,—I am much interested in the letter of "Formakin" (page 309) regarding this most fascinating alpine. The enclosed photograph, although being a poor one, will serve

G. VERNA ON A MORAINE.

to show the gentian in question entirely at home on a moraine in my garden. The plant here figured produced no fewer than seventy blooms in 1922, and although the effort somewhat overtaxed its strength, it is still full of blossom as I write. Smaller plants continue to thrive all over the moraine, but apparently this is not a species which can be expected to "ramp" in a British garden. One has to be content to see the little things barely holding their own year after year, and during the present month I shall total at least ninety flowers borne on twelve plants. So far as I can remember these were first set out in 1918.—R. H., *Stratford-on-Avon.*

INDISCRIMINATE HYBRIDISATION.

SIR,—When Barbidge and Baker published "The Narcissus, Its History and Culture," in 1875, the genus narcissus was divided into twenty species and they illustrated 109 species and varieties. Among those varieties are shown on "Plate IX. Narcissus Pseudo-Narcissus. A var. 'Empress.' B var. 'Emperor.'" Anyone consulting the Royal Horticultural Society's classified list of daffodil names, 1923, will find in the principal list over 2,400 names and in the supplementary list printed in smaller type "varieties lost to cultivation or suppressed by modern varieties," nearly 1,500 other names. There is some excuse for this appalling total as the daffodil is one of the first spring flowers to open and can so easily be brought into flower early in the season by suitable pot culture and judicious heat treatment. The increase in the number of varieties has extended the season, but there can be few cultivators of those charming plants who do not realise that those varieties are too numerous and a higher standard should be set before new names are allowed and added to that list.

At present there are about 600 known species of primula and the same merry game of crossing and naming goes on. There is money in it from the nursery trade outlook, and, while there is some justification for it, I do think it is being overdone.

It began many years ago with the European mountain primulas, fortunately some either will not mate or else produce sterile offspring, but the vast aggregate of P. pubescens is a race none can number and might have been even greater, only the so-called auricula was taken up as a florist flower, exact rules laid down to which it had to conform, and those rules imposed some check on its increase.

To-day the hybridiser has turned his attention to certain of the newer Asiatic kinds and rules for checking his zeal have not yet been framed.

Some good has been done as some of those hybrids have in the meantime a more facile constitution and some very beautiful plants, more easily cultivated than the true species have arisen. P. Cockburniana, whose fine colour has blended with others of the same section and given us useful garden plants. P. Red Hugh is one of the best of those mongrels; it comes very nearly true from seed, and by selecting the best coloured plants as seed bearers an even more striking strain might be produced, but every primula cross is not of the same excellence.

P. Juliæ was discovered in the Caucasus in 1901; it was introduced to cultivation about 1915, and has since been discovered by the hybridiser as a fruitful parent of so-called new varieties, Juliæ No. 2, Juliana, Wenda and many others have followed in rapid succession and no nurseryman showing alpines seems content till he has a hybrid of his own raising, which only differs materially from all the others in name.

P. Juliæ is a useful and beautiful plant, and seen early in the spring (and it can be very early), with its blooms reflected in still water in front and with a background of P. denticulata, the type forms a fine spring picture; but one cannot feel satisfied that many of its latest developments would give the same effect. Wenda is a striking colour, but it shrieks at every thing except itself. It is a shade one would welcome in a petunia, but seems out of place in a primrose. Unfortunately P. acaulis is not the only other primula with which P. Juliæ is fertile, a name Theodora emanates from Geneva. Whatever the first cross may have been like I cannot say, but later batches of seedlings are dreadful things, little better than bad P. officinalis forms, which vary from dull purple to dirty yellow.

Instead of devoting time and energy to raising such things it would be far better to

Digitized by Google

endeavour to solve some of the pressing problems of cultivating the true species. The nivalis group is full of difficulties and if one could only learn how to make them good perennials what joy it would give.

No hybrid has half the character of the natural species; a good gardener can with time produce a greenhouse variety of P. sinensis, but only nature can produce such species as P. melanops or P. secundiflora.—WILLIAM LOW, *Kincardineshire.*

FRAGRANCE IN FOLIAGE OF RHODODENDRON OREOTREPHES

SIR,—In several descriptions recently read of this fine Chinese rhododendron I see no mention made of the fragrance of the young foliage at this time of year. I was not aware that the shrub possessed this charming attribute until a few weeks ago when, in cutting out some dead wood and removing seed-heads, the tender, pea-green leaves emitted a refreshing, aromatic perfume much like that of our common bog myrtle.—CAMBRIA.

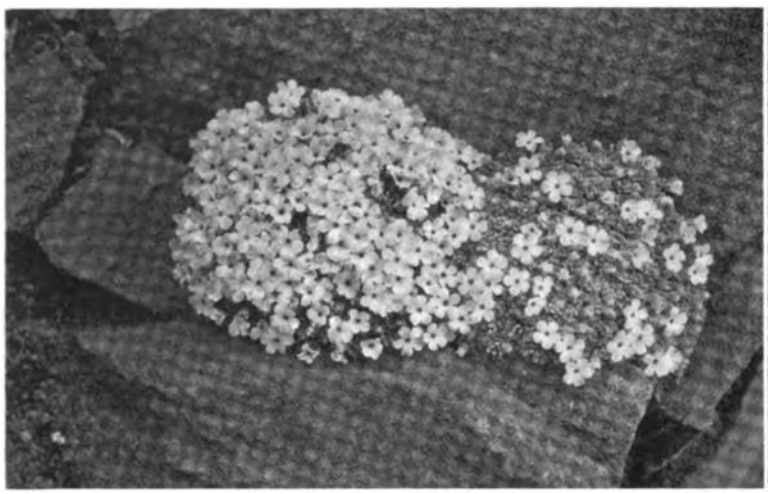
[This fragrance in rhododendron leaves is not at all uncommon. Practically the whole series containing, among others, RR. yunnanense, oreotrephes, ambiguum and Augustinii are aromatic. Other series with aromatic foliage are lapponicum, lepidotum, saluenense and heliolepis.—ED.]

ANDROSACE IMBRICATA AND ANEMONE VERNALIS.

SIR,—In your issue dated January 19th, page 38, you published a photograph of Androsace imbricata which I sent you. I now send you a photograph of the same plants in flower in case it may be of interest to any of your readers. I also enclose a photograph of another high alpine growing here—Anemone vernalis—grown from seed collected in Savoy.—(DR.) N. W. JENKIN, *Hindhead.*

THE VITALITY OF SEEDS.

SIR,—In your issue of the 7th inst., you mention in your notice of the succulent plants exhibited at the Chelsea Show, the mesembryanthemums shown by Miss Worth which had been raised from seed recovered from ss. Kinfauns Castle. The scientific significance of this fact may interest some of your readers. Any such may like to refer to Darwin's experiments concerning the vitality of seeds after immersion in salt water. Limit of space, of course, precludes any detailed reference to the subject in your pages, but Darwin's account of them (mainly in his letters to Sir J. D. Hooker in 1855), will be found in the second volume of "Darwin's Life and Letters," by his son, Francis Darwin. A footnote to one of the letters states that the results were published in the *Gardeners' Chronicle*, May 26th, November 24th, 1855.—A. J. HOWELL.



MANY SAY THAT ANDROSACE IMBRICATA WILL NOT FLOURISH IN ENGLAND.

ANEMONE VERNALIS FROM SEED COLLECTED IN SAVOY.

NOTES FROM CONTRIBUTORS

GERANIUM FARRERI.

LAST winter we secured a plant under the above name (which is, I understand, unofficial), and if this is Sp. F. 201, "two seeds" of which Farrer sent home from the higher altitudes of Tibet, it deserves all the good things said of it by its discoverer. So far this little stranger has behaved with the utmost willingness. Its first leaves, round, green and deeply lobed, somewhat after the style of those of G. argenteum, appeared above ground—for it is apparently herbaceous—in early spring. These made a loose tuft some 4ins. across and half as high, soon to be followed by the branching flower-stems, crimson like those of the leaves, bearing at each extremity a pair of buds. The first of these opened on May 27th, and the beauty of the flower exceeded one's most sanguine expectations. Opening perfectly flat, which is unusual, this blossom measured close upon 1½ins. across, and the broad, overlapping petals, which give the flower a well rounded form, are a most delicate and diaphanous shell pink, the central tuft of silvery stamens standing out prominently and bearing dark, nearly black, anthers. This little treasure is, one may presume, hardy beyond a doubt, and promises to be a great acquisition to our list of dwarf rock garden geraniums. We have it growing in a coolish, well drained pocket of shaley soil with limestone chips and leaf-mould in partial shade, and it seems to be smiling with health at every pore.—N. WALES.

[This plant was shown at Chelsea by Mr. C. T. Musgrave under the name of Farrer's Pink, and it was given an award of merit. An illustration of this plant appeared on page 407 in our issue dated June 7th.—ED.]

THE EFFECT OF WINTER ON PLANTS IN EAST YORKS.

THE following notes were made at the end of May this year on the effect of the long and hard winter on various plants and shrubs. The cold wet spring has been in some cases the saving of plants which were hard hit during the winter. A week or two of hot weather would probably have finished many of them, but as it is they have had a long time for slow recovery. The evergreens in this district were badly affected, and in exposed places privet, aucuba, veronicas and yews were left brown and shrivelled. Gorse appears to be killed. A fine old wistaria on the house is just now putting out a few leaves, but has failed to flower for the first time in our recollection. The white jessamine is much cut back by the frost. On the other hand, Choisya ternata and Piptanthus nepalensis, both considered delicate shrubs, are flowering well and seem unhurt. Young loquats, raised from seed which I brought from Lenno in 1921, have survived, and so has Physianthus, planted out last summer and still alive to the top. These are all on south walls. In the open, Buddleia variabilis has been killed to the ground, but is now growing from the roots, and a 6ft. specimen of Paulownia imperialis seems to be thriving. As an experiment I planted out two roots of greenhouse cyclamens last summer under a Turkey oak and an ash respectively, and both are alive and showing leaf. It remains to see if they flower.—RUTH BICKERSTETH, *Cottingham, East Yorks.*

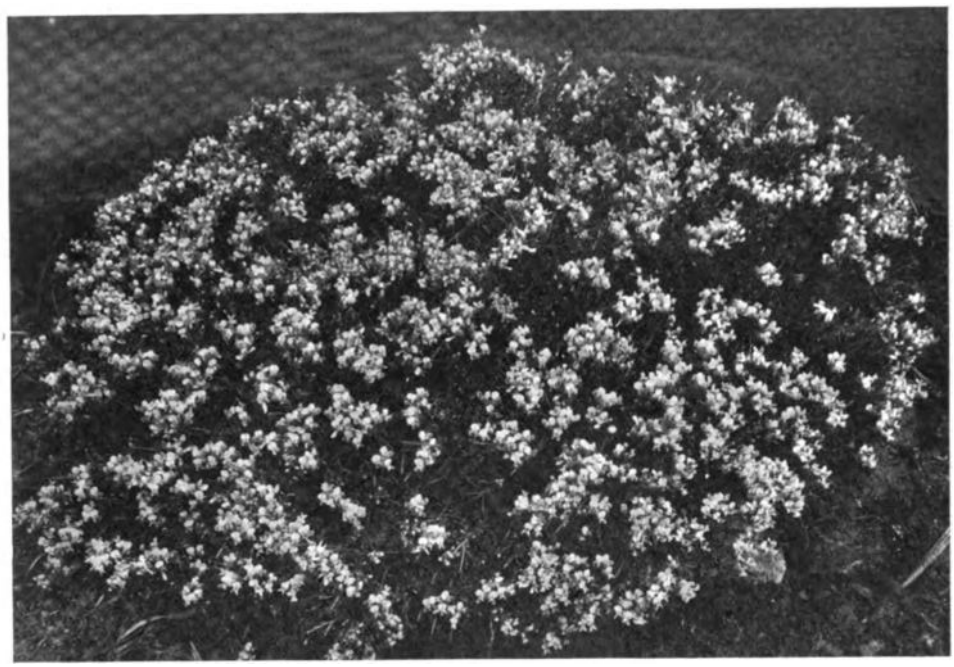
TULIPS IN THE ROSE GARDEN.

THIS season I have made the experiment, by no means new, but at the same time not a particularly common practice, of growing tulips among the roses. My rose garden is quite a small affair and the number of bulbs planted therefore is not very large, but, so far as the practice is justified by the results obtained, most emphatically it is worth while. The effect is particularly pleasing. Despite the unfavourable weather experienced during the last few weeks the tulips put up a very fine show, making a pleasant oasis of what would otherwise have been a desert of more or less bare rose bushes. Usually I have violas growing as a carpet for the roses, and when these are left for a couple of seasons a bright display is forthcoming early in the second year. The greater height of the tulip gives a somewhat more imposing effect perhaps, and at any rate it makes a change. A combination of the two might be worth trying. The growing of violas for two seasons and the planting of tulips to flower the second season should produce an effective result. It goes without saying, however, that such

combinations, and in fact interplanting of any description, should only be attempted where the soil is particularly good. In any case the rose beds will need a thorough top-dressing. With the very large number of varieties of tulips of various types at present in commerce it should now be possible for selections to be made and colour schemes created to suit all tastes.—HOWARD H. CRANE, *Eastcote*.

THE HEDGEHOG BROOM.
ERINACEA PUNGENS.

IN Erinacea pungens we have one of the most beautiful plants for the rock garden, as well as an interesting one, the colour of



A BEAUTIFUL PLANT FOR THE ROCK GARDEN. ERINACEA PUNGENS.

the flowers being distinct, probably more blue than any other hardy tree or shrub of Leguminosæ. It forms a dwarf, much-branched, stiff, spiny shrub, with sharp, erect, needle-like branches bearing a few narrow oblong-obovate or spathulate leaves which are opposite (one of the few instances where the leaves are opposite in Leguminosæ, other instances being in Genista horrida and G. radiata) and from ¼in. to ½in. in length, hardly noticeable against the dense green shoots, being only present at the end of the young branchlets.

The purplish blue flowers are arranged in clusters from three to eight on a short stalk just below the apex of the branchlets during April and May. It has rather a peculiar membranous silky calyx about two-thirds the length of the flower, which becomes inflated after flowering.

Erinacea pungens is a native of South France, Spain, Morocco and Corsica. It was first discovered by Clusius, and one can quite imagine his delight when he first saw this charming little shrub totally unknown to any other botanist at that time. Clusius describes and figures it in his "Hispanicus," which was published in 1576, and remarks on the woody root, large in proportion to the size of the plant. He also mentions that the inhabitants call it "Erizo," the Spanish for hedgehog, which its spines cause it to resemble, and undoubtedly from this he gave it its generic name, a name by which it is now generally known, although later Linnæus considered it a species of anthyllis, and called it A. Erinacea. It was first introduced into the country in 1759, but is still by no means common. Seed is produced very sparingly even in a wild state, and this is partly the reason why the plant is somewhat rare. Then, again, it is not recognised as a hardy plant, although there are few parts of the country where it could not be grown with success if planted in well drained soil and given a sunny nook in a sheltered part of the rock garden. Seeds should be sown as soon as ripe, this being the best method of propagation, although if young shoots with a small heel attached are placed in sandy soil under a handlight it is possible to get a few to root, but layering will be found a better method.

The illustration shows an exceptionally fine specimen 18ins. high and 4ft. in diameter growing here.—F. G. PRESTON, *Botanic Garden, Cambridge*.

OBITUARY

WILLIAM SERJEANTSON.

THE death of the Rev. William Serjeantson on June 9th, at the ripe age of eighty-eight, takes from us one of the best known men from "round the Wrekin." He was a very keen gardener; but as his parish was only a small one and as he divided his clerical responsibility with a priest of the Roman Church, he was able to give his attention to other hobbies. Ever since there was a show at Shrewsbury, until the war interfered with its annual clockwork regularity, he was the judge of wild flowers. He has left his garden after sixty-two years of labour a veritable little Paradise, full of good things. It is a happy blend of bedding out, formal trees, well thought out colour combinations and schemes, and plants old and new, with a well stocked kitchen garden, a hardy fernery and a miniature rock garden thrown in as side lines. Constant selection of the best and constant forethought and foresight were the keynotes of his wonderful success. An old friend writes thus to me: "His death is a loss to us all and his intense love of all things beautiful an example to us all." Let no one think that he was not proud of his parish. He was. The excellent restoration of the Parish Church, which was built by Robert Burnell, the famous Lord Chancellor of Edward I, will for generations to come be an index of the old rector's heart and the love he bore to all his surroundings.

JOSEPH JACOB.

[An illustrated article on the Rectory Garden at Acton Burnell appeared in THE GARDEN, October 15th, 1921, page 512.—ED.]

ANNOUNCEMENTS

Demonstration of Propagation under the auspices of the Botanical Society of Edinburgh, to be held at the Royal Botanic Garden, on Thursday and Friday, July 17th and 18th, 1924, Professor Wright Smith, M.A., F.L.S., F.R.S.E., President, in the chair.

PROGRAMME: Thursday, July 17th.

10 a.m.—1 p.m. Demonstration of Vegetative Propagation by means of Stem Cuttings, illustrated from fifty different plants.

2.30 p.m. Opening Remarks by President.

2.40 p.m. The Propagation of Clematis. By Miss Edith Philip Smith, B.A., F.L.S.

3.10 p.m. On Cuttings of Camphor. By Miss Mona Reid, B.Sc.

3.40 p.m. Horizontal Branch Propagation. By L. B. Stewart.

Friday, July 18th.

10 a.m.—1 p.m. Demonstration of Vegetative Propagation from Leaf and Root, illustrated from fifty different plants.

2.30 p.m. Propagation by Bulb Scales. R. J. D. Graham, M.A., D.Sc.

3 p.m. Root Cuttings. By L. B. Stewart.

3.30 p.m. Discussion of Exhibits.

British Carnation Society. — The following new carnations have been registered with the raiser's description of each:

CORAL GLOW, seedling, terra-cotta, flushed bronze; size, 3½ins.; mild fragrance; compact and free; stem strong.—Messrs. Allwood Brothers, Hayward's Heath. February 2nd, 1924.

SALMON BEAUTY, parentage, Wivelsfield Beauty, deep salmon; size, 3½ins.; sport; strong fragrance, habit and stem like its parent.—Messrs. Allwood Brothers, Haywards Heath. February 6th, 1924.

GEORGE ALLWOOD, seedling, blush salmon; size, 3½ins.; fragrance exceedingly good, habit and stem short and very free, of commercial type.—Messrs. Allwood Brothers, Haywards Heath. February 6th, 1924.

WEMBLEY WONDER, seedling, purple-heliotrope with buff ground over flushed cerise; size, 4ins.; fragrance strong, habit and stem very good.—Messrs. Allwood Brothers, Haywards Heath. February 6th, 1924.

JENIE MAIZE, sport of Jessie Allwood, deep maize, edged pink; size, 5ins.; mild fragrance, habit and stem identical with Jessie Allwood.—Messrs. Allwood Brothers, Haywards Heath. February 6th, 1924.

SIR PHILIP SASSOON, pedigree seedling, crimson; size, 3½ins. to 4ins.; good fragrance, very vigorous grower, stiff stem.—Messrs. Stuart Low and Co., Bush Hill Park, Enfield. February 19th, 1924.

MRS. E. WORMALD, sport from carnation Lady Alington; salmon, large flowers, sweetly scented, robust habit.—Mr. E. Wormald, Sheepwell House, Potters Bar. February 26th, 1924.

FRIEDESWIDE, seedling, pale salmon-pink, fair fragrance, habit and stem good.—Mr. Hubert Blake, Tower Cottage, Alverstoke. March 27th, 1924.

BIS GREENFIELD, seedling, deep scarlet; size, 3½ins.; medium fragrance, habit and stem stout and wiry.—Messrs. John Peed and Sons, West Norwood. March 27th, 1924.

LORD REVELSTOKE, seedling, deep cerise; size, 3ins.; mild fragrance, habit and stem good; parentage, Mrs. C. W. Ward × Triumph; calyx is very good.—Mr. A. J. Pointing, Appleton Nursery, Bulpham, Essex. March 26th, 1924.

SIMPLE GARDENING

WEEDS.

It has been almost impossible to keep flower, vegetable and fruit borders free from weeds since the early days of March, when seedlings began to get troublesome. Weeds are, undoubtedly, a nuisance, but they are a criterion to go by to a great extent. A blind farmer, being conducted over a new farm with a view to renting it for his son, who accompanied him, put many questions to his son as they passed from field to field. The son said, "Why! father, I cannot see a thistle anywhere"; the father replied, "Then we won't rent the farm my son; land that will not grow thistles will not grow corn."

I mention this occurrence as some measure of comfort for gardeners who find plenty of weeds, among them thistles, in their gardens. The Dutch hoe besides being beneficial to crops, where used regularly when the soil is in a fit state, kills seedling weeds wholesale. Every effort should be made to kill them while they are small and so prevent reproduction by seeding. Hand-weeding is absolutely necessary in some cases, and where groundsel, for instance, is nearing its flowering stage, it is not safe to throw the plants in a heap and leave them there without treatment. These, docks, dandelions and thistles should be subjected to fire by throwing the plants on the garden fire when the heat in the latter is fairly strong, thus destroying the seeds. A notched, pointed stick, dipped in oil of vitriol and used to stab the crowns of coarse weeds on lawns, will cause the death of the weeds. The vitriol, of course, burns and is poisonous.

LIQUID MANURE AND SOOT WATER.

The cultivator who can command an unlimited supply of farmyard liquid manure has a natural advantage over the one who must make the manure artificially. In both cases such manures should be freely diluted before they are applied to growing plants. We are now concerned more with the made liquid manure and soot water. Both ingredients should be procured first in a dry state and kept so while portions of each are being used. Both, too, should be made in separate tubs or similar vessels. In a tub containing 20 gallons of water an old sack containing 1 peck of manure or the same quantity of soot should be placed. As dry soot is not readily moistened through when bound up tightly in a sack or piece of scrim, it is a good plan to put a tied-up saturated bundle of moss or grass in the centre of the soot before tying up. Instead of sinking the bags to the bottom of the water tubs, suspend them in the centre of each by fastening a strong cord round the bag and tying the other end to a strong stick placed across the top of the tub. The manure, or soot bag, as the case may be, should be moved about freely twice each day for four days, when the water will become impregnated and turned into liquid manure or liquid soot. When used, 1 pint to a gallon of water will be, approximately, the right strength. It should be in a clear state, too.

THE TREATMENT OF TOMATOES.

The weather has a good or bad effect upon the plants and their fruits under glass as well as on those grown in the open air. Under glass the plants do receive protection from rains and cold winds; in the open air the success of

the crop depends, mainly, on the warm nights and sunny days. In both instances there should be similar treatment as regards the principle of training except in one particular, namely, that of stopping and the approximate date.

A perfect tomato plant should consist of the main stem and main leaves. Nos. 1, 1, shown in the sketch. The side shoots, Nos. 2, 2, are removed while quite small, and the trusses of fruit are retained in number according to the place wherein the plants are growing. In the open air four trusses are quite enough to retain to mature, and the top of the plant should be taken off the first week in August, as shown at No. 3. Plants growing under glass may be trained on to a later date—the early part of September to bear about seven trusses of fruit—and then stopped as shown at No. 4. The feeding should commence when two trusses are formed on plants under glass, one or two applications being sufficient for outside plants in hot summers; none being needed in dull, cool ones. A dry, buoyant atmosphere is essential for the plants, and this can be secured to a great degree under cover.

TRAINING CHRYSANTHEMUMS.

Owing to the recent long spell of wet weather and the lack of sunshine, these plants, in common with many others, have grown rapidly, being long-jointed in some instances and possessing stems much too soft and sappy. Now, the inexperienced cultivator may be well pleased with the appearance of such specimens, not so the old growers; the latter like stems and leaves that gradually harden as each month passes. Not till late in July will the roots have filled the large pots, and almost exhausted the nutriment contained in the compost, so that there should not be any hurry to feed. Many specimens will be better without stimulants in the meantime. The system of training should be decided upon at an early stage so that the strength of each plant will be concentrated in the stems and main leaves throughout. To grow surplus shoots 1ft. long and then discard them means waste of energy of plant. The main supporting stakes should be driven into the new soil, not into the old ball of soil and roots, else the latter will be damaged. Plants possessing three shoots, to bear blooms for exhibition or large ones for conservatory groups, should be supported by three stakes. Single-stemmed ones will need one stake; small bushes one stake looping the new branches to it. Larger bushes three stakes placed near the side of the pot—the tying material will thus enclose many branches, allowing the latter to grow in a natural form.

STAKING PLANTS.

If a herbaceous plant having a number of separate stems is to be staked, one, two or three stakes may be used. In every case the position of the stakes should be hidden as much as possible, while furnishing the necessary support to the clump when the soft tying material has been passed round it. Tuberous plants, such as begonias, that have produced a large amount of foliage may require support against strong winds by fixing short stakes into the ground near the tubers and merely passing the raffia round the stem just above the tuber, the stake being quite hidden under the leaves. In cases of staking choice pot plants indoors and outside, the stakes used should be very neat, all knots smoothed away, painted green or oak colour, and not be any thicker than is absolutely necessary.

GEORGE GARNER

Digitized by Google

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Beet.—Where such crops as beetroots and carrots have failed, now is a good time to sow seeds of the globe variety of beet and stump-rooted carrots. Sow the seeds thinly and keep the hoe at work in all parts of the garden.

THE FLOWER GARDEN.

Rambler Roses.—It is advisable to encourage the strong basal growths of rambler roses, and at this season they will need to be tied up rather loosely to prevent damage to the points, an injury which is often the result of carelessness on the part of the man with the lawn-mower. Suckers from both standard and dwarf varieties should be removed, weeds kept down and a close watch for aphis maintained. For spraying the trees with an insecticide a dull day should be chosen, or failing this, do the work late in the evening.

Violas.—To prolong a display of bloom, it will be necessary to examine the plants from time to time and remove the seed pods and old flowers.

Grafted Trees and Shrubs.—Such plants as lilacs, viburnums and rhododendrons are usually grafted on common varieties of the same genus, and it often happens that a large number of basal shoots appear at this season. The beginner is apt to think his plants are doing remarkably well, whereas, if these shoots are not removed, they will in time destroy the plant. The beautiful Viburnum Carlesii may be cited as an example. I have seen several plants almost ruined because the stock was allowed to develop. Plants on their own roots will only need the basal growths slightly thinned if they are numerous, and likely to become overcrowded. The grower should be careful to discriminate between the stock and scion, often the foliage is very much alike.

THE HARDY FRUIT GARDEN.

Red and White Currants.—The summer pruning of these useful fruits does not always receive the attention that it should. Where such work is carried out more light and air is admitted to the centre of the bushes, both fruit and trees being benefited. The leading shoots should be allowed to extend, but all side growths stopped at the fourth or fifth leaf. Cordon trees are treated in a similar way. Nets ought to be placed over the plantation before the currants begin to colour, or there will be considerable losses from birds.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Scarlet Runner Beans.—Plants raised from seed sown in pots or boxes under glass and set out some time ago will be well advanced, but those from sowings made out of doors should be staked now. If tree sticks are not available ordinary pea trainers turned on their ends and supported with stakes will answer quite well.

THE FLOWER GARDEN.

Chrysanthemums. — Border varieties should now be well advanced, and no time should be lost in having the stems securely staked and tied. Bushy plants of the Masse type produce many flowers and may require anything from three to five stakes each, so that the plants will be held in an upright position when plants are in bloom.

Lythrum Salicaria rosea.—We might class this loosestrife among the neat and stately growing herbaceous plants, and those who have raised a batch of seedlings should have these set out in lines 1ft. apart; the seedlings being placed 6ins. distant from each other in the lines.

Sweet Peas.—The plants should now be showing flowers. One year plants raised from autumn-sown seed were not a bit earlier in flowering than the plants raised from spring-sown seed germinated and brought on under glass; both were in flower on the same date. But there was a very great difference in their heights. Those plants raised from November-sown seed were at the time of flowering over 6ft. high, while the plants raised from the March-sown seed were only 4½ft. high when coming into flower. If a prolonged supply of good flowers is expected one must keep picking and allow no seed pods to form on the plants.

THE HARDY FRUIT GARDEN.

Strawberries.—There may be a delay in a somewhat late season of putting the straw between the plants, or of spreading the nets on, but the work should be done at the earliest opportunity, and also nets hung up in front of cherry trees on walls.

FRUITS UNDER GLASS.

Melons.—These plants should be progressing rapidly now and where the beds are somewhat narrow or shallow, it may be advisable to apply a top-dressing further to sustain the plants. Continue to maintain a moist atmosphere so that thrips and red spider will be kept in check, as reliance cannot be placed on mild fumigations to kill these pests.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Arctotis aureola.—This beautiful South African plant is very difficult to propagate by means of cuttings and it is not generally known that it is readily increased by layering. For this purpose the plants should be turned out of their pots and planted out in the open, or better still, in a cold frame; afterwards layering them in the usual way. By this method a good stock of young plants is easily maintained. When well rooted, the layers should be lifted and placed in 48-sized pots, afterwards standing them in cold frames. The latter should be kept close for a week or so until the plants become established. Afterwards they should be given plenty of air and ordinary cool greenhouse treatment.

Arctotis revoluta and A. aspera.—Although both these plants are desirable for the greenhouse, they are by no means such showy plants as A. aureola. They are both easily propagated at this time by means of cuttings, which root readily under a bell glass in a cool greenhouse.

Calceolarias of the herbaceous section should now be raised from seed. As the seed is very fine the seed pots should be prepared and well watered the day before sowing, using a light, sandy compost. The seed should be sown on the surface and barely covered with a sprinkling of sand. Cover the seed pots with a piece of glass and keep them shaded until germination takes place. These plants require perfectly cool treatment at all times, with moist atmospheric conditions. When large enough to handle the young seedlings should be pricked off into pans or boxes containing a light, rich compost; later transferring them to small pots. Subsequent treatment consists in potting them on as they require it. Green fly should be guarded against by frequent light fumigations.

Malmaison Carnations.—As these plants pass out of flower set young stock aside for potting on. Good healthy plants should also be selected for layering. For this purpose the plants should be turned out of their pots, planting them out in cold frames, afterwards layering them in the usual way. When well rooted, lift and pot up into 48-sized pots, using for this purpose a good medium loam. To ensure free drainage old mortar rubble may be used instead of sand, as all carnations are lime lovers. After potting, the plants may be stored in cold frames or in a cool greenhouse.

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Hollyhock Disease (Felsted).—The fungus causing the hollyhock disease first appears in minute rusty spots on the undersides of the leaves. Then the brown spots increase in size and spread rapidly. When the fungus pustules are fruiting they break through the skin of the leaf, producing spores, each possessing two cells at the point of growth. Our correspondent should examine the leaves under a magnifying glass and so ascertain if these conditions prevail. If so, the plants affected should be uprooted and burned. The fungus on the lawn may be killed by pouring strong liquid manure, undiluted, into holes made 9ins. deep with an iron rod and 1ft. apart; or by using sulphate of ammonia in tiny holes a few inches deep and 1ft. apart. The nitrogenous matter from the decaying fungi causes the grass to grow strongly and of a dark green colour.

FRUIT GARDEN.

Pear-tree Shoots Dying (Mrs. C.).—No doubt the roots of the tree are in an uncongenial rooting medium and their past and present condition is the real cause of the tips of the young shoots dying. There are no insects—grubs—in the shoot sent. The pear thrives best in a rich loam, inclined to be heavy, but the drainage of the land should be sound. It would be best so to prepare ground and plant a young tree in the autumn.

MISCELLANEOUS.

To Eradicate Woodlice (A. C. B.).—Woodlice like darkened places where there is also dryness. They eat much food and are always found close to a supply of it. It is not possible to apply boiling water near the roots of plants, only in open quarters where this risk does not exist. But in confined places, such as the greenhouse, place cut potatoes in small, empty flower pots, scatter a small quantity of bran on the cut parts, add some dry moss, and lay down the pots, inverted, on the floor or stage. Examine every morning and shake out the woodlice into boiling water. It should not take a long time to clear away the pests.

How to Rid a Pond of Scum ("Enquirer," Dunfermline).—As there are fish in the pond it is not possible to take drastic measures to clear it of scum. Water snails are, in same cases, objected to, but they will clear the surface of scum. Tench are better than carp for the same purpose. Either, or both, of these experiments could be tried, the tench being the least objectionable.

To Make Grape Wine (J. H. S.).—Although a few tendrils and the ends of young shoots improve the flavour of the wine, the shoots themselves do not make such good wine as that from the berries and bunches at thinning-out time. The following are quantities and the process. Use a tub, also a small cask. In the tub place 24lb. of grapes and young shoots; add 2 gallons of water after well bruising the fruit with a wooden article. Stir well, cover with a blanket, allow it to stand for twenty-four hours. Draw off liquid through a tap near the bottom, add 1 gallon of clear water, stir and draw the liquid off. Wash the tub; return the clear liquid and 1 gallon of clear water. Add 18lb. of brown sugar, stir, then make a paste of half an ounce of baker's yeast and tepid water. Place three pieces of ordinary toasted bread on the liquid in the tub, and cover these with yeast paste. Cover the tub with a blanket. The temperature of the room should range about 65°. In from thirty to fifty hours the fermentation should be complete. Then draw off liquid again, passing it through a clean woollen cloth or blanket and fill up the cask. Leave the latter slightly tilted so that the froth can run out, fill up with clear water from time to time. In ten days or so active fermentation will cease, the bunghole may be closed, but a vent-hole must be made near and duly pegged. Put in a small quantity of isinglass during cold weather in autumn.

Names of Plants.—(G. R.).—1, Billbergia nutans; 2, Gasteria species; 3, Cannot recognise other specimen without flowers. ——(W. V. P.).—A, Veronica prostrata; B. Arenaria montana; C, Saxifraga canaliculata.——(Col. S., Perth).—1, Pernettya mucronata; 2, Pieris japonica.——("Hedgerley").—1, Iris Gambal; 2, I. pallida var.; 3, I. Mrs. Newbronner; 4. I. squallens var. ——Mrs. C.—1, Saxifraga canaliculata; 2, S. cuneifolia; 3. Dicentra formosa.

Clay Challenge Cup.—The Clay Challenge Cup, presented by Messrs. Clay for a rose of good form and colour not in commerce, possessing the true old rose scent, such as may be found in the old cabbage or Provence rose, in Marie Baumann, General McArthur, etc., will be offered at the Royal Horticultural Society's Fortnightly Show at Vincent Square on July 8th next. The scent known as "Tea Rose" is not, for this competition, to be accounted as true old rose scent. Not more than three varieties may be shown by any one competitor, and at least three and not more than six cut blooms of each variety, are required. The cup will only be awarded once for the same rose. It is hoped that this year all leading rose growers in the United Kingdom will send in entries for this cup. The public shows each year an increasing interest in roses, especially those possessing the true old rose scent, and the Royal Horticultural Society hopes that Messrs. Clay's generosity in presenting this cup will lead to the introduction of new roses with good scent.

BEAUTIFUL, FRAGRANT, CINNAMON VINES

Beautiful Leaves, Dainty Flowers, Exquisite Perfume

The Cinnamon Vine from the Oriental Land is one of the most beautiful of climbers, the most fragrant, and the easiest to grow. No home is complete without it. They will surround your windows, porch and trellises, making them "Perfect Flowers of Beauty." They will grow 30ft. in a single season. Nothing like them. Their abundant blossoms perfume the air for a long distance with the most delicious fragrance. No words can describe their exquisite perfume.

No one should miss planting these charming Vines. They will be a constant delight to every lover of Vines and flowers. They stand the hardest winter, and burst forth in all their beauty very early in the spring. When first introduced the roots sold for £2 each.

There is nothing will give a home a more homelike and cosy appearance, or is a surer index of refinement and culture, than these Oriental Fragrant Vines, twining and climbing about the porch, windows and trellises. They are Nature's Own Drapery from the Oriental Land, where graceful beauty is most highly prized.

Beautiful, Hardy, Entrancingly Fragrant.
Grows in Sun or Shade—Wet or Dry.
No Insects Ever Trouble—No Winter Harms.
Once Planted will Grow a Lifetime.

Barr's Seeds for July Sowing

OF FINEST STRAINS AND TESTED GROWTH.

For the Flower Garden.

Antirrhinums, Aquilegias, Campanulas, Delphiniums, Forget-me-nots, Gaillardias, Geums, Hollyhocks, Lupins, Pansies, Papavers, Polyanthus-Primroses, Sweet Williams, Stocks, Violas etc.

For the Vegetable Garden.

Beet, Cabbage, Carrots, Cress, Mustard, Onions, Peas, Parsley, Turnips, Radish, etc.

For the Rock Garden.

Special List of dwarf-growing Hardy Perennials, Alpines, etc., for July sowing in the Rock Garden.

All Lists free on application.

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know* ? *this Booklet ?

If you know it, there is no question at all about it: you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence; but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

EDITORIAL

THIS article is written round a correspondent's answer to a short note of a week or two ago entitled "Encouragement." It is entered in this place in the paper partly because I like to have an article noticed—as a newcomer to horticultural journalism my vanity is pleasantly titillated, surely a sufficient excuse?—and partly because it brings forward a point which requires an answer. It is good news to hear from people who appreciate THE GARDEN: it is also gratifying to learn that readers are helping the paper along by pointing out its merits to their friends.

"The leader on 'Encouragement' in THE GARDEN for June 14th would, I venture to say, be perused with much interest by readers everywhere. The Editor has taken us into his confidence by telling us, that since the paper appeared in its new form, he has received numbers of congratulatory letters. That is good news! But he goes further than this; he 'let's the cat out of the bag' by a candid admission, when he says certain critics have expressed their opinion that the catering of THE GARDEN has been in the direction of the *advanced* gardener. May there not be some truth in this? May not the man whose garden is only of moderate dimensions have a feeling, after reading some of the articles by learned specialists in their particular domain of horticulture, that they bordered on the academic, and, therefore, held little in common for him? I have a deal of sympathy for the average gardener—and by this I mean the possessor of the small, or at any rate, moderate-sized plot, and I regard the one or two letters received by the Editor with respect to catering for the advanced school as representing quite a large proportion of readers of the paper. We are assured, however, that—whatever the policy of THE GARDEN may have been in the past—it is not its intention to ignore those whose interest in gardening may be real and keen, but owing to limitation of ground, have perforce to 'cut their coat according to the cloth,' and who, if they are unable to boast of a rock garden, may be able with not a little pride, to point to a *rockery* in their little garden 'brimming over with flowers to mark the days and weeks and months.' It seems to me that by the introduction of 'Simple Gardening,' the Editor has earned the congratulations of all who look at gardening in its widest sense, and by this Forward Movement, has considerably enhanced the scope of the paper. I have often passed on THE GARDEN to friends, who, while praising its high level and the beauty of its illustrations, have said to me, that many of the articles were more calculated to arouse enthusiasm in the hearts of Fellows of the R.H.S. or others whose particular interest was of a botanical order, and that there was little to help the beginner, or the owner of a small villa garden. That charge cannot be sustained any longer, at all events, with the advent of 'Simple Gardening.' It is conducted by a man of wide experience, both as a practising horticulturist and contributor to the gardening press. He will give us of his best, couched in language that even the veriest tyro may understand. We are up against this fact to-day, more than ever before, that *amateur* gardeners—whether we like the designation or not—are in the ascendancy; they represent by far the greatest number of those who wield the spade, and that, among such, the majority own comparatively small gardens. To them is submitted advice about lowly plants and vegetables which they are able to grow, and this appeals to them more than a dissertation upon forest trees, aquatic plants, orchids, or fruit-growing under glass, and, therefore, I cannot help thinking that while THE GARDEN, with its traditions, will continue to cater for the advanced school, it has enhanced its reputation in providing food for thought for the larger body of gardeners. I have read THE GARDEN regularly for very many years—longer, indeed, than I care to remember—and knowing its worth in early days and its recent expansion, I feel sure that the step it has now taken will not in any way lessen, but will add to its value and circulation by making new friends. We may all do something by pushing it along, by showing our copy to those who have not seen it in its new dress. I wish it all success."

The point that requires an answer is this: Our correspondent perhaps takes it for granted that a small gardener is always in a beginner's standard and that a beginner remains a beginner. Now we have found in THE GARDEN that this is not the case. However small a plot a man may cultivate, sooner or later he will find that some particular flower, vegetable or fruit becomes, perhaps not a passion, but a favourite. Therefore we do not expect those readers who may be satisfied with our "Simple Gardening" page at the beginning of their experience to consider it after a year or so as their only solace and comfort. But apart from that we hope that even beginners will find something of interest in the other pages of THE GARDEN. Gardening knowledge is only a question of degree and it is amazing how quickly one's standard may rise provided that an intelligent interest is always taken in the subject.

E. H. M. C.

IRISES FOR EVERY GARDEN

BY A. J. BLISS.

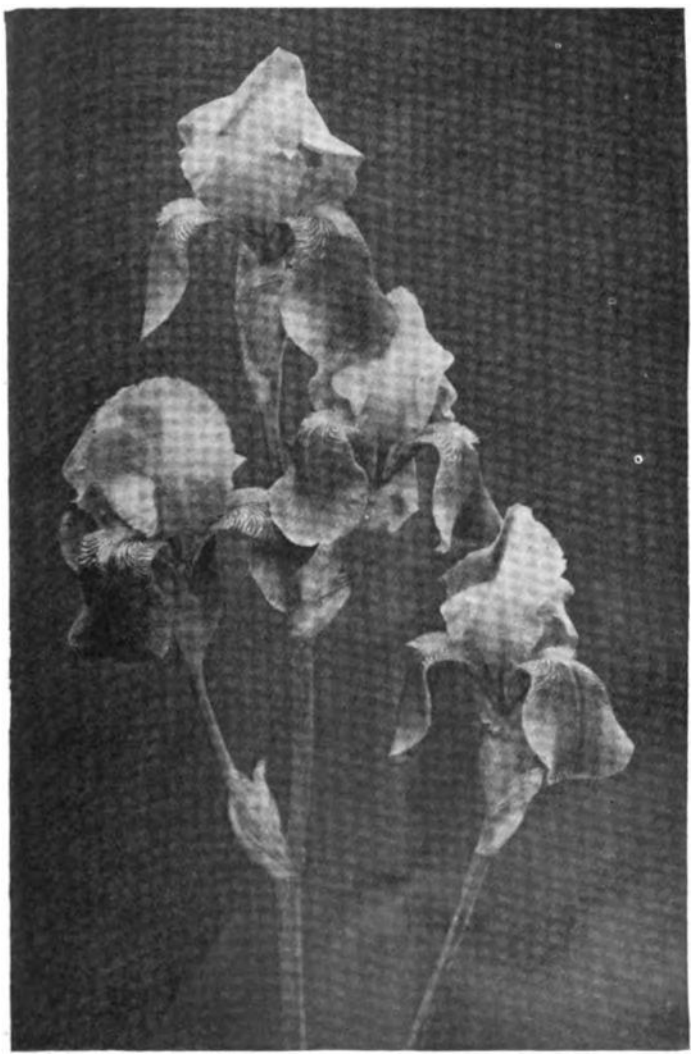
MANY GARDENERS FIND A SUITABLE CHOICE OF IRISES FOR THEIR GARDEN A MATTER OF SOME DIFFICULTY. IN THIS ARTICLE A SELECTION OF SOME OF THE BEST VARIETIES IS GIVEN.

TO make separate selections of the best irises for every type of garden is manifestly an impossibility: for garden ideals are many, and every maker of a garden will impress something of his individuality in the making of it. But, broadly, all garden ideals can be divided into those in which the general effect is chiefly aimed at—colour-scheme gardens and colour massing—and those in which the individual plant or flower is the first consideration. Admittedly these aims overlap, and in all gardens will be combined in varying proportions.

Colour being the most important consideration in the garden, the colour classification will be followed as far as possible, the best in each colour group being noted, followed by any that may be distinct or useful for special purposes.

WHITE.—The three best—in three different types—are *Kashmir White*, tall, with large pure white flowers of fine form; it is reputed to be a shy flowerer, but with abundance of lime—a heavy dressing every year—it grows well and flowers freely. *Taj Mahal*, an American seedling of quite a different type, being derived from I. plicata; a strong grower, with large flowers, pure white except for the light lavender reticulations on the haft. *Mystic*, large flowers of fine form on rather close spikes, white with red-violet reticulations on the hafts; it is exceptionally free, and should eventually supersede Mrs. H. Darwin. To these may be added: *Bolingbroke*, which is practically as fine as Kashmir White, with larger flowers, though less distinctive in form. Being a seedling of Trojana-pallida and Kashmir White, it may succeed where Kashmir White fails. *White Queen*, a pure white, with smallish flowers and comparatively dwarf, but very free, and the best for the front of the border. *Innocenza*, a cream-white, very free and quite distinct from any of the above, being derived from variegata.

I. CITRONELLA, OF PALLIDA HEIGHT AND HABIT.



PRACTICALLY A VIOLET-PURPLE BICOLOR, IRIS PROSPERO.

PLICATA.—All plicatas are beautiful, but few are outstanding. Of the violet-blue margined plicatas, *Princess Osra* is undoubtedly the finest in size, form, and in the delicate effect of the clear and defined spotting of the margins. Others that may be noted are: *Mme. Chereau*, which, though eighty years old, is still worthy of a place in any garden; *Ma Mie*, which has a rather deeper and bluer frilling; and *Hilda*, in which the margin-colour is still deeper and more defined, and which, from its closer habit and exceptional freedom, is the best for massing. Of the red-violet plicatas, *Francina* is practically the only one, but there is scope for improvement in this colour type. Of the rose and lilac plicatas, though there are very many, and all beautiful, no one can yet be picked out as exceptional. The squalens-plicata type is comparatively new, but some think Verdier's *Mercedes*, though now twenty years old, is still the most beautiful of these; while M. Denis' *Mme. Chobaut* would appeal equally, perhaps, to others.

AMŒNA.—This has always been a small section. *Rhein Nixe* is one of the strongest growing and freest of all irises, but the colour of the falls is too pale to make an effective contrast with the white standards. *Daphne* has deeper violet falls, and is otherwise a counterpart of Rhein Nixe,

Digitized by Google

and probably will eventually supersede it. *Tristram* is exceptional for the contrast of the white standards and indigo-violet—almost black—falls, and supersedes the older Thorbeck. *Dalila* is a distinct and striking flower, with cream-white standards and rich red-purple falls.

BICOLORS.—These include irises of really very different types: (1) Those with tall branching Trojana-pallida habit, blue-violet or red-violet; and (2) those of more Neglecta habit, with the same colour range. The Dominion race also comes naturally here, though some merge into the bicolor squalens.

Of type (1), the tall bicolors, the best are *Lord of June*, violet-blue; *Prospero*, which, though classed as a squalens, is practically a violet-purple bicolor; *Paladin*, a distinct iris with very large flowers, and early; *Baronet* and *Crusader*, for their special blue tone; and lastly, *Magnifica*, light red-violet, a magnificent iris worthy of its name.

Of type (2), *Dominion* is, of course, unique. *Perfection*, with deep indigo falls, is still unmatched. *Azure* and *Du Guesclin* are the best blue-toned for massing or large groups, the former richer and deeper coloured and a rampant grower, and the latter a brighter blue and of closer habit. *Monsignor* and *Syphax* are, perhaps, the two best red-violet of this type. Monsignor has fine-formed flowers, and Syphax is distinct and striking, but neither are outstanding.

Of the Dominion race the best of the violet and violet-blue are *Swazi*, *Hyperion*, *Bertrand* and *Yeoman*, in the order given. *Cardinal* and *Romola* are the two best of the red-violet, and perhaps the most beautiful of all. Of the deep-coloured, ranging from pansy purple to blackish purple, the best are *Moa*, *Tenebræ* and *Duke of Bedford*. Of the semi-squalens type, *Bruno* is unique, *Glamour* perhaps the most beautiful in colouring, and *Majestic* the most imposing in size and form. In the same class as these are *Lent A. Williamson*, comparable with Bruno, being freer flowering but less rich in colour, and *Ambassadeur*, comparable with Moa, having smaller flowers, but even darker falls.

SELF VIOLET, BLUE AND RED.—Of the lighter coloured the best are: *Ballerine*, violet-blue; *Gabriel*, *Ann Page* and *Morwell*, somewhat lighter and bluer; and *Leonato*, lavender-mauve. *Princess Beatrice* is still the finest pale lavender-blue pallida. *Queen Caterina* is unsurpassed for the satiny lustre of its pale lavender-violet flowers. And *Souvenir de Mme. Gaudichau* is by far the finest deep violet-purple iris yet raised. Besides these, there are some, not so outstanding, perhaps, but distinct and notable. *Mlle. Schwartz*, for its height and large flowers of clear fresh pale lavender-blue; and *Leoné Trenance*, with perfect-formed flowers of a luminous violet-blue, and exceptionally free. *Mrs. Tinley* is the best of the Ciengialti hybrids; and *Miranda* is a very distinct violet iris of Ciengialti type, but taller and early flowering. For massing, *Commodore*, when better known, will be widely grown. Of ideal compact habit, yet increasing very fast, the colour is a uniform self violet. For a blue tone, *Rodney* or *Isis* are the best.

Of the "red" selfs, *Seminole* is undoubtedly the best, far surpassing any other in the brightness and purity of its colour, and is very free. *Opera* is one of the richest coloured of irises, an indescribable blend of crimson-toned purple and sepia. *Edouard Michel* is still the best of its colour, a reddish claret.

Following these come naturally the shades of colour that range from mauve to pink. *Lady Byng* is by far the best and purest mauve, and will probably prove a more popular colour than its parent Phyllis Bliss. *Sweet Lavender*, two shades of rosy mauve, owes its charm perhaps as much to its light and open branching habit as to its colour. *Troost* is unique in colour, a raspberry-rose, with large flowers of fine distinct form. *Isoline* is still unmatched. *Dream* at first opening seems almost a true rose colour, but really is a lilac rose. *Aphrodite* is of similar colouring but a finer flower, and with a much better habit. *Susan Bliss* is the best of these and the nearest to a true rose-pink; but *Queen of May* is still worthy of a place in any garden.

I. DAPHNE, WHICH WILL PROBABLY SUPERSEDE I. RHEIN NIXE.

ONE OF THE BEST OF THE DOMINION RACE, I. BERTRAND.

Digitized by Google

SQUALENS—There is probably more scope for improvement in this class than any other, since, except for Bruno and Ambassadeur, there are few outstanding varieties, and they mostly lie on the borderland of other sections. It is remarkable, too, that *Jacquesiana* after eighty years is still the best "red" squalens, though *Mrs. Cowley*, of similar colouring, is better for massing, being of closer habit and freer. The only other "full" squalens of note is *Prosper Laugier*, which is exceptionally free and a strong grower. It is often compared with Jacquesiana, but it is really quite different in colour effect, which is brown rather than red. *Asia*, the finest, after Bruno and Ambassadeur, of those now classed as squalens, is intermediate between the older type of squalens and trojana. *Alcazar*—almost a purple bicolor—is of splendid habit, but the colouring is dull and undistinguished. *Dora Longdon*, an iris of beautiful colouring and exceptionally free, is on the borderland of squalens and amœna. And *Iris King* is so near a variegata that it is practically superseded by Flammenschwert.

I. FLAVESCENS IS INDISPENSABLE WHERE BROAD EFFECTS ARE DESIRED.

VARIEGATA.—*Flammenschwert* is undoubtedly the finest pure variegata; the flowers are large and of fine form, and the yellow is rich and clear. *Marsh Marigold* is distinct with lighter yellow standards and more "solid" coloured falls with a defined yellow margin. *Knysna* is the tallest and, being exceptionally free and strong-growing, is indispensable for massing. *Citronella*, though classed as a variegata, is really in a class by itself, being of pallida height and habit, and the fall colour is a crimson-toned red instead of the typical variegata brown-red. *Shekinah*, a luminous pale yellow self, is also of pallida type and will eventually supersede flavescens. Meanwhile, *I. flavescens* is still indispensable where broad effects are desired. *Aurea* is the richest deep yellow self.

To conclude, the irises in this selection number about eighty, all are distinct and notable, and some thirty-five are outstanding.

HOW TO HYBRIDISE IRISES

BY SIR ARTHUR HORT, BT.

IT is well known that most irises cannot fertilise themselves, the stigma being so placed that the pollen does not fall on it, as in self-fertilised flowers. It may be as well to mention that the stigma (or stigmatic surface) is the sticky "lip" under the end of the style branch: the anthers, which bear the pollen are below this. Again, it is unlikely that pollen borne by wind would catch on this surface. It follows that the iris is "cross fertilised," that is, requires the co-operation of insects. Irises of the most popular and well known section, the bearded group, are in fact fertilised by bees. It is most interesting to watch a bee at work: guided, it is supposed, by the "signal" (which in the group under consideration is a "beard," in other sections a "crest," or modified beard, or a streak of different colour to the rest of the "fall"), he, or rather it, goes straight down the narrow walled passage made by the "haft" of the fall to secure the drop of nectar which lies at the base. He cannot get at it otherwise, because the edges of the fall turn upwards so as nearly to meet the style branch above, forming with it a tunnel; he must go between the walls and not over them; if, as nature intends, he perches on the signal, the fall is depressed a little by his weight, so that the tunnel is enlarged and he has an easy passage. You may sometimes see him try a short cut, and fail. (If this description seems complicated, and the terms are unfamiliar, a glance at the diagram at the beginning of Mr. Dyke's new "Handbook of Garden Irises," will make all plain.) As he goes down and then returns backwards, pollen from the anthers, which adhere to the underside of the style branch above him, gets brushed off on to his back and sticks to the hairs. Then he enters another flower, and, as he goes down, some of this pollen rubs off on to the stigmatic surface, if it is ready; when it is ready, it stands out a little from the style branch, to which at first it adheres, and becomes sticky. The bee then has, in pursuit of his own ends, unconsciously paid the iris for his honey; he has enabled No. 2 flower to set seed and propagate its kind, by conveying to it the pollen of flower No. 1.

The hybridiser takes his cue from the bee, and does slowly and clumsily what the insect does rapidly by unerring instinct. Artificial pollination may be done with a stick of sealing wax rubbed on the sleeve so that it becomes charged with electricity and the pollen grains will stick to it; they can then be wiped off on the stigma of the flower which is to be fertilised. But perhaps an easier plan, with a flower whose parts are so large and conspicuous as those of most irises, is to nip out a whole anther with a small pair of tweezers; the tweezers firmly held and the pollen stroked off on to the stigma. Several anthers of the same kind may be carried in a small box from flower to flower; wind is sometimes troublesome, or one may drop an anther by mistake down the "tunnel" or on to the ground. The flower which has been treated may be marked with a small label (or price ticket) tied on below it to show what the cross was; the simplest way is to put a number corresponding to a number in a pocket book against which the cross is entered. Thus, if I cross Iris pallida with I. trojana, I may label the pollinated flower 23; then, when I gather the seed, I look at my pocket book and find 23, "pall. × troj."—in indicating a cross the seed parent should be mentioned first.

If it is desirable to make sure of the cross, certain further precautions must be taken. The flower should be tied up in a muslin bag till the stigma is ready, to keep the bees off, and bagged again after pollinating. But amateurs will probably not care to disfigure their borders in this way, and will take the chance of being forestalled by a bee or followed by one bearing pollen which prevails over that artificially applied.

There is no mystery about this simple process; with a little practice a dozen flowers may be pollinated in a few minutes. No doubt it is best to do it as early as possible; some practitioners, I believe, even assist the bud to open with their fingers, and so cut out at all events the risk of the anticipating bee. It is difficult to work in a high wind, and it is useless in wet weather, since the pollen grains then burst—as our most competent authority, Mr. Dykes, informs us.

Digitized by Google

It is useful to tie the stem bearing a pollinated flower to a short stick; iris stems break rather easily in a wind, especially under the weight of seed pods. Then, when old stems are being cut down, as they should be, unless seed is wanted, those tied up are easily recognised and spared.

So much for a rather fascinating pastime. However, many amateurs who have little time for such deliberate hybridising may yet find great pleasure and profit in saving seeds naturally formed, letting the bees do the preliminary work for them. In that case, to secure interesting results, it is only necessary to start with a fair selection of good irises growing together, and either to keep bees or have a neighbour who does so. Some kinds, such as pallida, bear abundant seed naturally; I have often seen five or six pods on one stem. Nor need the old stems be left long on the plants on the chance of seed; it is easy to see when pods are forming, in fact, the ovary begins to swell almost as soon as the flower has faded.

HINTS on the CULTIVATION OF IRISES

BY W. R. DYKES.

THE genus iris contains so many species of totally different types that no general rules can be given for the cultivation of irises as a whole. Some gardeners seem to think that, because our native yellow I. Pseudacorus grows by the river-side, all irises want abundant moisture, while others have no knowledge of the existence of any irises

IRIS KÆMPFERI ON A HILLTOP, PROVING THAT THIS IS NOT A WATER-LOVING SPECIES.

besides bearded irises and Spanish irises. There are, however, many different sections and groups within the genus, the members of each of which need approximately the same treatment.

In cultivating unfamiliar plants it is usually helpful to consider the climate of the country from which they come, and this rule holds good with irises. The commonest irises in our garden are hybrids of certain bearded species belonging to the Pogoniris section and these species are all natives of regions which have what geographers call a continental climate and where the long period of drought during the summer months forces plants to undergo a resting period. This enforced rest seems to economise their energies and to prepare them for an outburst of rapid and continuous growth as soon as moisture comes, either in autumn or with the melting of the winter snow. Consequently, in attempting to cultivate these irises in our gardens we must plant them where they will enjoy all the available sun and in such positions that sharp drainage will keep the rhizomes comparatively dry. In southern countries the ground is often so hot in summer that it is almost impossible to rest the bare hand for long on a rock and the iris rhizomes, which love to grow in sunny, rocky positions, get a ripening which they miss here. However, we must do our best for them by planting them practically on the surface, so near it, in fact, that by the time the earth has settled down, the upper half of each rhizome will be exposed. The other essential point about the cultivation of bearded irises is that they all come from districts with a limestone soil and they never remain healthy for long in a soil that is deficient in lime. The best addition to soil in which irises are to be grown is old mortar rubble, for this, besides supplying lime, seems to improve the texture both of heavy and light soils. If mortar rubble is unobtainable, it is best to use finely ground chalk on light soil and slaked lime on heavy soil, applied, if possible, when beds are being dug in readiness for planting and in the autumn to established beds.

In the early spring of this year there were numerous complaints from iris growers, especially in the north and in the colder districts, that parts of their plants looked unhealthy and were collapsing. This unhealthy, pale, yellowish appearance is, I believe, not directly produced by disease, but by premature growth from imperfectly ripened rhizomes. This unhealthy condition of the rhizomes may lead to attacks of rhizome rot, which causes the tufts of leaves and the stems to fall over at flowering time. The remedy is to cut out all diseased parts and to dress the remainder and the surrounding soil with superphosphate of lime, of which the acid reaction is fatal to the bacillus which causes the disease. If the healthy remnants of the plants can be moved into fresh soil, which has been freely sprinkled with superphosphate, so much the better.

There are two other diseases to which bearded irises are prone in this country; one is leaf spot and the other a reddish-brown rust, which I first obtained from Sir Michael Foster's garden at Shelford and from which I have never yet been entirely free, though I am inclined to believe that it could be stamped out if I had the time to spray all my plants at weekly intervals for a month or six weeks with a solution of copper carbonate. Only a few irises seem really liable to this rust.

The leaf spot is much more common and more unsightly, for the spots or patches of brown on the leaves spread in size and increase in number until the foliage is more or less destroyed. This weakens the rhizomes and lessens the chance of flowers in the succeeding year. The remedy is, I believe, abundance of lime or chalk in the soil to keep the rhizomes healthy and frequent spraying with disinfectants, such as permanganate of potash or Bordeaux mixture, when there are signs of an attack.

The minor sections of bearded irises, such as the Regelias from Turkestan and the Oncocyclus species from Syria, Asia Minor and Persia, are so dependent on thorough ripening in summer that we have to dig up the rhizomes about the middle of July and keep them warm and dry until they are replanted in October. On the other hand, the Himalayan Pseudoregelias are difficult to cultivate in this country because, although they enjoy the moisture of our average summer, yet they want dry autumns and winters. In their native homes they doubtless lie entirely dormant under the snow until they are roused to life again by its melting in spring.

The beardless or Apogon species have, as a rule, much more slender rhizomes than those of the bearded irises and

Digitized by Google

consequently are, as a whole, far less adapted to withstand drought. Some, such as the sibiricas, have compensation for the slenderness of their rhizomes in the extraordinary abundance of the actual roots, which supply the plants with the copious moisture needed to sustain the exuberant growth of the leaves and flower stems. Others, such as the Californian species, have slender rhizomes and yet, at the same time, remarkably few roots, an indication that their growth is slow and that they will flourish in a soil which is inclined to be cool and well supplied with nourishment. Some irises are obviously water plants and in these there are always present minute black specks, which can be clearly seen, when a leaf is held up against the light. They are found, for instance, in our native I. Pseudacorus, in its American cousin, I. versicolor, and in I. lævigata, which is a totally distinct species from I. Kæmpferi, from which the Japanese have evolved their innumerable garden hybrids. I. Kæmpferi is, therefore, not strictly a water iris and the Japanese have found the truth of this and so arrange their iris gardens that the beds stand high and comparatively dry in winter, though they are surrounded by and soaked with water during the period of rapid growth in spring and summer.

All the bulbous species of iris, with one exception, enjoy a rest in summer, and therefore should be planted in rather light, well drained soil. The single exception is I. xiphioides, sometimes called the English iris, though it is a native of the Pyrenees. There, except in winter, when the ground is doubtless frozen, the bulbs get abundant supplies of moisture and flourish in the wet alpine pastures. This fact should be remembered when Spanish irises do not do well. The best course is probably to plant I. xiphioides instead.

Much has been written on the best time to transplant irises. Bulbous species should, obviously, be moved in summer, when the bulbs are dormant, and, with regard to the others, the best rule is to examine the roots and never move the plants unless new roots are being made. Plants shifted at other times merely lie in the ground without taking hold of it and suffer accordingly. Iris sibirica will, therefore, be moved either early in spring or as soon as the ground is really wet in September and while the plants still have time to form new roots before winter. The Californians will only be moved during spring and early summer, while Japanese irises and the Spuria group may be moved either in spring or in August or early September, provided that the soil is moist till the plants have taken hold.

Bearded irises of the Pogoniris section may be moved when in flower, provided that the rhizomes do not remain long out of the ground, for otherwise the young roots will wither. If they have to go a journey, then August or early September are best, for the main roots will then be mature and many of them still unbranched, so that they are prepared to branch out and lay hold of their new homes. Avoid July, for it seems probable that it is during this month that the flower buds are formed for the following year. Disturbance at this time is apt to lead to loss of bloom in the following season.

A DISCOURSE ON NYMPHÆAS—II

BY F. LAPLACE.

THE water lily hybrids, the result of somewhat complicated hybridisation, give a very varied series of colours. It is unnecessary to give a complete list, as a choice of good varieties is much more useful:

Note.—L. M. stands in all cases for Latour Marliac.

WHITE.

Albatros (L. M. 1910).—Very large milk-white flower.

Candida (Bohemia).

Gladstoniana Richardson.—Very robust, pure white.

Hermine (L. M. 1910).—Tulip-shaped flower, pure white.

Virginalis (L. M.).—Very large flower, pure white, early and late flowering.

ROSE-COLOURED AND SALMON PINK.

Colossea (L. M. 1901).—Flowers flesh pink, flowering continuously till the first frost.

W. Doogue (Dreer.).—Rose-white.

Goliath (L. M. 1912).—Tulip-shaped flowers, curling outwards, white washed with bright rose.

Lusitania (L. M. 1912).—Very interesting on account of its large and abundant flowers, white speckled with bright rose.

Marliacea rosea (L. M. 1887).—Very large pale rose flowers.

Masaniello (L. M. 1908).—Very robust with a quantity of rose flowers.

Newton (L. M. 1910).—Bright rose vermilion, narrow petals, giving the flower the appearance of a star.

Mrs. Richmond (L. M. 1910).—A fine variety with pale rosy-mauve flowers.

Marguerite Laplace (L. M. 1912).—Very robust with a quantity of pale rose flowers, brighter towards the centre.

Somptuosa (L. M. 1909).—Flowers very full pale rose dotted with carmine.

YELLOW, ORANGE-YELLOW, COPPER.

Aurora (L. M. 1895).—Flowers passing, from the first day to the third, from a yellow pink to dark red.

Chrysantha (L. M. 1905).—Flowers passing from yellow to a yellow vermilion.

Comanche (L. M. 1908).—Large flowers, coppery yellow ochre.

Graziella (L. M. 1904).—Flowers pale orange-red.

Indiana (L. M. 1912).—Very pretty variety, the colour passing from orange yellow to an intense coppery red.

Marliacea chromatella (L. M. 1877).—Very robust and floriferous, bright canary yellow.

Moorei.—Bright yellow.

Odorata sulphurea grandiflora (L. M. 1888).—Flowers sulphur yellow, strongly scented.

Paul Hariot (L. M. 1905).—Fine variety with pale yellow flowers shaded to copper yellow.

NYMPHÆA MASANIELLO WITH ROSE-COLOURED FLOWERS.

Digitized by Google

Pygmæa helvola (L. M. 1879).—Very pretty small variety with tiny canary yellow flowers.

Seignometi (L. M. 1893).—Flowers pale yellow shaded to canary yellow.

Sioux (L. M. 1908)—Narrow petals of a coppery yellow, fringed with red.

RED-CRIMSON.

Andreana (L. M., 1895).—Pretty variety with red flowers shading to ochre.

Arethusa (Dreer).—Flowers with wide petals bright rose-crimson.

Atropurpurea (L. M., 1901).—One of the most robust and most floriferous of the varieties. Very large dark crimson flowers.

Attraction (L. M., 1910).—Very large flowers, dark purple-red.

Ellisiana (L. M., 1896).—Fine variety; flowers large red-vermilion.

Escarboucle (L. M., 1909).—The bright vermilion-red of this variety places it in the first rank of the red lilies.

ONE OF THE BEST OF RED NYMPHÆAS, N. ESCARBOUCLE.

Froebeli (Froebel).—This seems to be a descendant of N. sphœrocarpa, but it has dark wine-red flowers.

James Hudson (L. M., 1912).—The flower is tulip-shaped, a fine dark rose with mauve lights.

James Brydon Dreer.—This recalls Arethusa, but the colour is slightly stronger.

Laydekeri fulgens (L.M., 1893).—Fine variety with medium-sized red-purple flowers.

The varieties Laydekeri lilacea, L. purpurata, L. rosea, are fine plants, differing from each other by the intensity of their colour.

Marliacea flammea (L. M., 1894).—Extremely robust, very large flowers, wine-red.

Marliacea ignea (L. M., 1893).—Differing from Marliacea flammea by its fine carmine-red.

Meteor (L. M., 1909).—Very large flowers, purple-red.

Robinsoniana (L. M., 1895).—Result of the same hybridisation as N. Andreana, its colour is a fine dark yellow shaded vermilion.

Sanguinea (L. M., 1894).—Fine dark carmine-red.

Sultan (L. M., 1910).—Brilliant cherry red.

Vésuve (L. M., 1906).—A good variety with large red flowers strongly shaded purple.

VARIEGATED.

In this series the flowers, pink or red, have streaks or stripes of white. The varieties recommended are: Darwin (L. M., 1909), Esmeralda (L. M., 1912) and Livingstone (L. M., 1909).

The varieties of semi-hardy water lilies with blue flowers are fairly numerous in addition to the types enumerated above. The following can be cultivated with success out of doors in the summer:

Pennsylvania, pale blue.

Pulcherrima, a fine blue.

William Stone, dark blue.

Scutifolia, from the Cape, blue.

Finally come the zanzibarensis, the flowers of which easily attain 18cm. to 20cm. diameter, and bloom from July till the first frost.

Some of these types and varieties are uncertain in colour.

The following varieties are true to colour:

Frank Treelove, dark reddish brown.

William Ward, a fine rose-pink.

Gracilis, pure white.

CULTIVATION, ETC.

The cultivation of water lilies is of the simplest. They ask very little. The chief thing is a sunny position so that the water is easily warmed: the current should not be too rapid, for the same reason. The soil should be rich. Good clean soil should be used to which can be added some pond mud. A good precaution is to prepare a compost at least a year in advance, of, say, two-fifths clean soil, two-fifths pond mud, one-fifth well rotted stable manure. The whole should be thoroughly mixed and turned once or twice in the year. Water lilies respond equally well to the action of artificial manures. Calcined bone or horn can be used, each plant receiving 100g. to 200g., according to the richness of the soil.

Several methods of growing can be employed. That which gives the best results is to plant the lilies directly in the soil, when their growth is greater and quicker. Cultivation in sunk baskets is also good, but then a change of soil should be made every two or three years; that is to say, a part of the used earth should be removed and replaced by new suitably mixed with manure. As regards depth of water or, rather, depth of submersion, it is important that the water should not be more than 40cm. deep, the bottom of the pond being in proportion. The baskets can then be arranged on pedestals of a suitable height.

The best time to plant is the summer, but one can plant from April 15th till August 15th. Planting is quite simple, but it is a good thing to put a stone on the top of the plant, without, of course, covering the bud, so that the rhizome is not disturbed.

It may also be useful to state that some small varieties can be grown in small aquaria in the house. These are N. pygmæa, N. p. helvola, etc.

The cultivation of half-hardy water lilies out of doors is a little different. Planting should not be undertaken till after May 15th and only till the end of June. In the autumn the rhizomes must be taken up and put in the hot-house in vessels or baskets, the temperature being maintained at 12°–15° C. During the winter they lie dormant, and in the spring the temperature should be slightly raised to 18°–20° C., so as to start them.

To increase their number the rhizomes are usually divided. This can be done from the spring till towards the end of August. Sowing is also sometimes used for hardy water lilies. The ripe seeds should be sown after they have been gathered in vessels full of earth and placed in baskets so that the level of the earth is 1cm. below that of the water; later the young plants should be pricked out and the depth of water increased in proportion to the development of the plants.

The same method of sowing is used for the half-hardy water lilies, but the temperature of the water must be kept

Digitized by Google

at between 18° and 20° C.; their development is, however, very rapid, and seeds sown in February flower in August of the same year.

A certain number of parasites attack water lilies. There are grubs which can be got rid of by spraying with nicotine; then the larvæ of water insects, which must be relentlessly pursued; and then certain plants, which may hinder the development of the rhizomes and the leaves—for instance, Elodea canadensis, various potamogeton, etc., which can only be got rid of by being torn up repeatedly. If there are no fish in the pond, a solution of sulphate of copper can be poured straight into the water; and the potamogeton will quickly disappear.

Finally, it need only be mentioned that the rapid development of the leaves may prevent the flowers from opening properly in summer; it is, therefore, a good thing to suppress from time to time some of the leaves from the centre. This does not in any way injure the health of the plant or its development.

NOTES FROM A CHALK GARDEN

BY F. E. STERN.

ALL GARDENERS WHO LIVE ON CHALK SHOULD FIND THESE NOTES OF GREAT INTEREST. THEY RECOUNT ACTUAL EXPERIENCES OF TESTING PLANTS IN A CHALK PIT GARDEN.

MANY people seem to think that only a few plants will grow on chalk soils. This is a fallacy, and should be known as such to all those who live on chalk or lime soils. The rhododendron family and kalmias are known haters of lime, but even with the rhododendrons there is a suspicion that some of the new species from China may tolerate it. R. rubiginosum has grown and flowered in our garden at Highdown, Sussex, for the last few years. The heath family are also said to dislike it, but we have found by experience that EE. carnea, mediterranea, darleyensis and australis all grow as well on lime as elsewhere.

There is one great rule to remember when planting on chalk, and that is to break up the subsoil. Gardeners are apt to dig a hole in the chalk, then plant their tree or shrub, and after a few years, when the foliage turns yellow, the plants are said to dislike lime. In many cases the reason is that the chalk which is as hard as rock underneath, acts like a pot, and plants become pot-bound and starved. They would grow perfectly well if the hard subsoil beneath was broken up.

Iris unguicularis (or I. stylosa, a pleasanter name) begins to flower in January, growing in pure rubble chalk at the bottom of the cliff. It flowers and grows better there than in good soil in other parts of the garden.

The spring is a glorious time in the chalk garden, as nearly all bulbs enjoy the perfect drainage that well broken chalk rubble gives. Crocuses, daffodils, chionodoxas and fritillarias all revel in the perfect conditions. The crocus species are well worth growing, and C. Sieberi, one of the best of them, has been splendid this year. Daffodil King Alfred flowers here with great vigour: its long stems and deep yellow flowers are most attractive.

All anemones enjoy chalk. The first to flower is A. Ingrami, the deep blue windflower from Greece, and A. Pulsatilla, a real chalk plant. They both seed themselves, and always

A GENERAL VIEW OF MR. STERN'S CHALK PIT GARDEN.

Digitized by Google

seem to look best where they are self-sown. One thinks that no anemone could beat these two until A. fulgens bursts out with its scarlet flowers. Other anemones are also out at this time, such as apennina, blue and white, and the most delicate coloured anemone of all, A. nemorosa Robinsoniana. There are plenty of others to make the herbaceous border gay in April before the larger plants grow up, such as the St. Brigid and St. Bavo types.

All the tulip species add colour to the garden in April. The first to flower is T. Kaufmanniana and then T. præstans, and at the end of April T. Greigi is splendid with its huge scarlet flowers; but perhaps the best of all in this garden is T. Eichleri. The latter withstands the weather best, and its dazzling scarlet is beyond description. Then T. Sprengeri finishes up the tulip season.

All the irises, except Kæmpferi and its type, which dislike lime, grow well here. Two uncommon irises, I. Wattii and the hardy form of Iris chinensis, have been planted out for two years, and now are making buds for the first time. I. Wattii comes from North India. This curious plant forms long stems, from the top of which come the leaves and flowers.

¶ Before leaving the iris family I should like to draw attention to the Oncocyclus and Regelia irises. These irises are easy to manage if properly treated. They should be lifted in June or July and planted out again in October. There are such magnificent species of these types, such as Hoogiana, Gatesii and Susiana, and many hybrids, that it seems a pity they should not be more popular. A mass of Iris Hoogiana in flower is a sight worth seeing—surely one of the most wonderful sights in all gardening.

All the different muscari and scillas grow and seed themselves readily on chalky soils. Scilla messeniaca is an unusual and very charming bulb worth growing in the rock garden.

We have just begun to experiment with the erythroniums: the best so far is E. californicum, which flowers well and is increasing in a half shady place in good soil under beech trees. All hardy cyclamens also grow well under beech trees, and do not seem to mind the deep shade in summer.

It may be of interest to know that Myosotidium nobile is flowering well in our Sussex garden. The plants were put out over a year ago and are growing with great luxuriance. During January and February they had a sheet of Windolite spread 1ft.over the top of them with the sides open, and although we had over 12° of frost last winter, they have come through without damage.

There are some shrubs which grow on the pure chalk rubble at the base of the cliffs and are absolutely at home there. The best are Spartium junceum, the Spanish gorse, Ulex hispanica, and the forsythias. These all flourish and grow with great vigour in rubble in which many would hesitate to plant anything. The same may be said of the shrubby veronicas. Many speciosa hybrids were planted on this rubble chalk cliff as an experiment some twelve years ago, and they have never been touched or helped in any way, and are now over 8ft. high. The veronicas are fine evergreens for seaside gardens. They withstand the gales better than most other shrubs, and different species and varieties are in flower during nearly every month of the year. The earliest to flower in this garden are V. macrocarpa, a tall-growing shrub with long racemes of white flowers; and V. Lewisii, which has an attractive pink and white flower and seems hardier than V. macrocarpa. V. Hulkeana is the next in succession, and is, perhaps, the prettiest of them all. It does best here on the rubble of the cliff, facing south. Veronica cupressoides, though usually quoted in catalogues as a dwarf, grows to 3ft. high and looks more like a young cypress than a veronica. It is covered with small pink flowers in June. After these come the angustifolia type, a hardy form which really seems to enjoy the south-west gales. These plants grow into large specimens and are simply covered with flowers during the summer. We have three colours here, white, pink and blue, and also a dwarf form known to me as Bowles' variety.

There is another fine summer-flowering variety called Girdwoodiana, with lavender blue flowers. This variety is quite unlike that of any other veronica I have seen. It has withstood 12° of frost and seems to be hardy. Then in August all speciosa hybrids begin to flower and keep the garden gay right through the autumn with every shade of pink and purple to deepest red, and blue and white. This family of shrubs is invaluable to wind-swept gardens near the coast.

All the viburnum family seem to like the chalk. It is difficult to choose the best. V. fragrans comes out in February and scents the air when nothing much else is out, but V. Carlesii in my opinion is superior to it. A much neglected viburnum is bitchuiense: it is not particularly attractive when small, and was once considered an ugly type of Carlesii. When it grows up to some 4ft., it is a fine plant. It has larger flowers than Carlesii—which are white and the underneath of the truss is pink. The scent is as good as Carlesii and the plant seems to grow more vigorously.

With regard to the berberis family, the true berberis grows better on the chalk than the Mahonia section. What finer shrubs exist than BB. stenophylla, Darwinii and Knightii? I do not think than any of the newer Chinese berberises are on a level with these three. The family all take two or three years really to establish themselves on chalk, but when once they have taken hold, they go ahead fast.

Another great family which enjoys the chalk is the buddleia. B. variabilis grows on the pure chalk rubble and shows its appreciation by seeding itself in all directions. B. alternifolia is another first-class plant. The weeping habit and way of flowering all down the old wood makes it especially unusual and attractive. B. Fallowana is a new and delightful member of this family and seems to be perfectly hardy. Another one with the uncomfortable name of B. cylindrostachya flowered here for the first time last year. It is after the type of variabilis, but the flowers are a mauve which is almost blue. Buddleia Colvilei should also be grown in all gardens on the south coast. It is one of the finest flowering shrubs we have. It grows into a large evergreen bush and its flowers are a delicate rose colour unlike any other buddleia flower.

It is curious that in some families one or two members enjoy the chalk and the rest dislike it, or *vice versa*. The eucryphias and tricuspidarias are two such families. E. cordifolia and T. dependens both enjoy the chalk; on the other hand, according to my experience, E. pinnatifolia and T. lanceolata dislike it and die quickly. This is a fine problem for some botanist to tackle. It is doubly curious because, as Mr. Bean tells us in his book ("Trees and Shrubs Hardy in the British Isles"), these four shrubs all come from Chili, and E. cordifolia and T. lanceolata both come from Valdivia and the Island of Chiloé. There are two more families which all grow in this soil with one exception in each case. The ceanothus and cistus families all grow splendidly except Ceanothus papillosus and Cistus Loreti. All the spring-flowering shrubs, such as ribes, cydonias and lilacs, grow quite happily. Lilacs seem to flower on the chalk with greater vigour and with larger flowers than they do on other soils. I think two of Farrer's new syringas, Potannini and Juliæ, one white and the other lilac, both sweet-smelling shrubs, are the best of all the new syringas lately introduced from China. The introduction of so many new plants from China in the last twenty years has entirely revolutionised the making of gardens on lime soils. If one leaves out the rhododendrons, there is hardly a shrub that has been introduced which will not grow on lime; also, I am not satisfied yet that even some of the rhododendrons will not grow on lime.

Other recent introductions from China which do well here and are worth growing are Caryopteris tangutica, Potentilla Farreri, Philadelphus manshuricus, Hamamelis mollis, Cotoneaster lactea, Prunus dehiscens, Acer griseum and Davidia involucrata. Many good clematises have recently come from China, such as CC. Armandi, montana var. Wilsoni and montana rubra, and a yellow August-flowering one, tangutica. These are all first-class climbers which are extremely easy to grow and are happy, like all the clematis family, growing in lime. New Zealand and South America also produce a number of plants which will grow on lime. From New Zealand, besides the veronicas, we get Plagianthus Lyalli and the olearias, of which the best seem to be O. macrodonta and O. semidentata. We also get the pittosporums. These fine evergreens grow over 12ft. high and do not seem to mind the wind. South America provides us with such plants as Desfontainea spinosa, Berberis Darwinii, Berberidopsis corallina, Solanum crispum, Fabiana imbricata and the fuchsias. On the other hand, very few of the North American shrubs will stand lime.

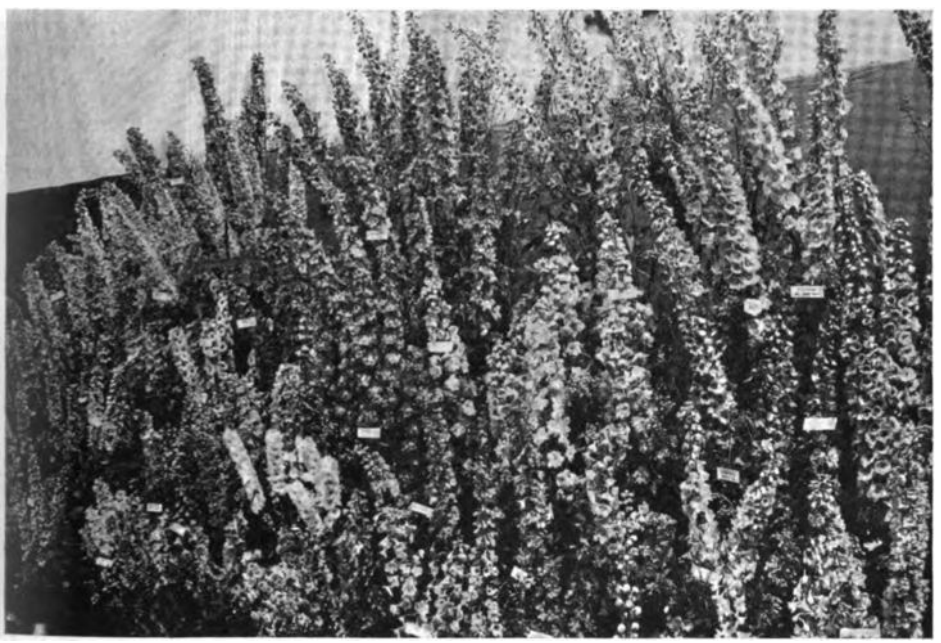
Part of the garden in the chalk pit is devoted to tropical-looking plants, such as Chamærops Fortunei and yuccas.

Digitized by Google

The yucca is one of the few shrubs that really requires lime. If anyone takes the trouble to put some pieces of chalk round about their roots and then dig down in a year's time, they will find the roots of the yucca clutching every piece of chalk within reach. Here we also have Beschorneria yuccoides, kniphofias and eremuri. The latter are most interesting and easy plants to grow. They should be planted in a place sheltered from the wind, with excellent drainage. They cannot stand wind, or dampness at their roots. The different sorts go on flowering most of the summer. Another class of plants which do very well indeed on chalk are roses. I do not believe that clay is necessary for them, or that they like living on clay any more than human beings do. All hybrid roses grow splendidly. Some plants of Mme. Ravary have been flowering here for twelve years and are still in a flourishing condition. There are also many species which are wonderfully fine plants and should be grown in every garden on the lime, such as RR. Hugonis and Moyesii.

SWEET PEAS, PEONIES AND DELPHINIUMS AT VINCENT SQUARE

ALTHOUGH it was supposed to be "strawberry time" at the fortnightly meeting of the Royal Horticultural Society on June 24th and 25th, there was only one trade exhibit. The Mrs. Harding Cup for Peonies exhibited by amateurs was not awarded. There were only two exhibits for the cup, and the Council thought that the flowers shown were not up to standard.



MESSRS. BLACKMORE AND LANGDON'S STAND OF DELPHINIUMS.

Messrs. Robert Bolton and Son had a large exhibit of sweet peas very tastefully arranged in baskets. The flowers were in excellent condition and exceedingly well grown. Here were to be seen their new varieties, Wembley, soft pale bluish lavender; and Empire, pale soft rose. Other notable sorts were Powerscourt, lavender; Picture, creamy pink; and Supreme, satin pink.

Close by, Messrs. Sutton and Sons had a large exhibit of these beautiful annuals. This exhibit was also very tastefully arranged. Notable sorts were Burpee's Giant White, Sutton's Blackseeded Cream, Warrior (chocolate-maroon), Picture, Sensation (scarlet), Hawlmark Pink, Butterfly, Spencer (red and white bicolor) and Apple Blossom.

Yet another attractive exhibit came from Messrs. J. K. King and Sons, Limited, of Coggeshall. Outstanding varieties were Daffodil, Celeste, Faerie Queen, Royal Purple and Wild Rose.

A large exhibit of peonies was shown by Messrs. R. H. Bath, Limited, and these were interspersed with delphiniums and gladioli. Conspicuous among the peonies was Sarah Bernhardt (see "New and Rare Plants"). Other outstanding sorts were Mandarin, a single-flowered variety of rose colouring with golden centre; Mme. Emile Lemoine (see "New and Rare Plants"); Lady Carrington, Canarie, Flambeau, Critic and Karl Rosenfield.

An excellent exhibit of delphiniums came from Messrs. Blackmore and Langdon. Conspicuous among them were Mrs. Townley Parker, sky blue single with white eye; Mrs. Christie-Miller, large-flowering cream sort; Sir Douglas Haig, deep purple and blue, a wonderful flower; Purple King, Millicent Blackmore, blue and mauve, black centre; King of Delphiniums, blue and plum, white eye. A new variety is Edward Bromet, of rich purplish colour and a white eye. This should soon become popular.

Mr. T. Carlile also had an exhibit of these beautiful plants. Here were to be seen Norah Ferguson, which received an award of merit; Peggy Wiseman, mauve with paler suffusion; Mrs. Robert Ascroft, sky blue, deeper at edges; Loddon Guard, large spike pale blue suffused mauve; Mrs. Thos. Carlile, Parma violet, petals shading to pink; and Blue Lagoon, blue, primrose eye. Mr. Carlile also showed peonies and irises.

Greenhouse plants were shown by Messrs. John Peed and Son, and Messrs. Stuart Low and Co. The latter also showed roses and carnations.

A large batch of Bermuda lilies (Lilium longiflorum eximium) was exhibited by Messrs. L. R. Russell, Limited. The flowers were very good. They were grown for the Commissioner for Bermuda, British Empire Exhibition.

Roses were shown by Messrs. B. R. Cant and Sons, and the Rev. J. H. Pemberton.

Several vases of sweet peas were shown by Major Geoffrey Lubbock of Pangbourne. They were well grown and conspicuous among them were Wild Rose, Picture, Powerscourt, Matchless and Jean Ireland (Improved).

Messrs. Barr and Sons had a airly large exhibit of irises and delphiniums. They also had an excellent exhibit of vegetables, including carrots, radishes, tomatoes, kohl-rabi, marrows, chives, peas, tarragon, cauliflowers, etc.

Perpetual-flowering carnations and Dianthus Allwoodii were shown by Messrs. Allwood Brothers.

Messrs. Harkness and Sons showed their well known lupins, also poppies. Among the lupins were Yellow Hammer, clouded yellow; Golden Thoughts, fawn, yellow wings; Merry Times, biscuit fawn, shaded fawn; Sunshine (Improved), buttercup yellow; Joy, apricot pink, yellow wings. There were some wonderful shades to be seen in many of the flowers shown.

Lettuces in great variety were shown by Messrs. James Carter and Co., and this exhibit aroused much interest. Here were both cos and cabbage varieties. Prominent sorts were Purple Oak Leaf (cabbage), Green Oak Leaf (cabbage) and Green Curled (cabbage).

Irises and gladioli were staged by Messrs. Lowe and Gibson. Among the gladioli were many beautiful seedlings.

Irises and lilies were shown by Messrs. R. W. Wallace and Co. The following were prominent among the irises: Ed. Michel, Prospero, Citronella, Rodney and Delavayi. Among the lilies were Golden Orb and Mrs. R. O. Backhou

Messrs. Wallace also showed peoni

Digitized by Google

Mr. J. C. Allgrove sent some very interesting plants, including Eremuri magnifica and Warei, the brilliant Trollius Ledebourii, Rodgersias sambucifolia and æsculifolia, delphiniums and peonies.

Alpines, sprays of flowering trees and shrubs, lilies and Cypripedium spectabile were included in an exhibit set up by Mr. G. Reuthe.

Perpetual-flowering carnations were staged by Mr. C. Engelmann.

Mr. Charles Turner showed some interesting shrubs.

Poppies, Canterbury bells and some very showy pelargoniums were staged by Messrs. Godfrey and Son.

Mr. G. J. Daws of East Moseley showed two dishes of Royal Sovereign strawberries. The fruits were firm, of good size and colour.

Mr. W. Wells, jun., showed hardy plants and alpines. Plants of outstanding merit were Erigeron Merstham Glory, lavender; Gillenia trifoliata, Achillea Cerise Queen and Delphinium Cashmiriana album.

Several dishes of strawberries were shown by Sir Charles Nall-Cain.

Delphiniums and peonies were shown by Messrs. Kelway and Son. Among the peonies the following sorts were conspicuous: Kelway's Success, a double-flowered variety with pink guard petals and cream and flesh pink central petals; Belgium, bright cherry, golden anthers (this is not quite a double); Lena Ashwell, rose; Queen Alexandra, white, golden centre. Of the delphiniums the following were prominent: Lloyd George, blue and violet, white eye; Boy Kelway, blue suffused rose, white eye, striped blue; Smoke of War, violet and purple, black centre; and Bluebell, bright blue. St. Brigid anemones were shown by Messrs. Reamsbottom and Co.

A very tempting array of strawberries was shown by Messrs. Laxton Brothers. There were many baskets of their new strawberry The Duke. This variety is claimed to be the earliest forcer, the earliest outdoor variety, the heaviest cropper and the most vigorous grower. The fruits are of good size and of excellent flavour.

Several flowers of Magnolias Watsoni and parviflora floating in bowls were shown by Mr. J. H. Lowinsky.

The following firms showed hardy plants: Messrs. Ladhams, Messrs. Maxwell and Beale, The Chalk Hill Nurseries, Messrs. Tucker and Son, Messrs. Carter Page and Co., Messrs. M. Prichard and Sons, Messrs. Gavin Jones and Ingwersen, Messrs. Herbert Vigers and Co., Messrs. John Waterer, Sons and Crisp, Messrs. Bakers, Mr. F. G. Wood, Messrs. W. H. Rogers and Sons, Messrs. Skelton and Kirby, The Orpington Nurseries Co., Misses Hopkins, and Messrs. Rich and Co.

NEW AND RARE PLANTS.

CARPENTERIA CALIFORNICA LADHAM'S VARIETY.—A larger flower than the type, having six or seven petals. Award of merit. Shown by Messrs. Ladhams.

CHARIEIS HETEROPHYLLA.—An interesting annual with light blue flowers, very much in the way of agathæa. Shown by the Director, R.H.S. Gardens, Wisley.

CLADRASTIS TINCTORIA.—Sprays of the yellow wood were shown. The white flowers are borne on terminal panicles and somewhat resemble a white wistaria.

PEONY SARAH BERNHARDT, SHOWN BY MESSRS. R. H. BATH.

Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

CORDYLINE AUSTRACHIS (C. australis × C. Banksii erythrorachis).—Very much in the way of C. australis, but panicle rather larger, more open and feathery. First-class certificate. Shown by Mr. Reginald Cory.

CORNUS KOUSA CHINENSIS.—A larger form than the type. The plant appears to be very free flowering. Shown by the Director, Royal Botanic Gardens, Kew.

DELPHINIUM TATSIENENSE.—A Chinese species with almost gentian blue flowers. This plant is about 18ins. to 2ft. high and forms neat rounded bushes. Shown by Mr. R. C. Notcutt.

DELPHINIUM NORAH FERGUSON.—A very fine variety. The flowers are light blue, suffused rosy mauve and are semi-double. This plant should prove very popular. Award of merit. Shown by Mr. T. Carlile.

DIMORPHOTHECA PLUVIALIS.—The flowers are white with a distinct purple zone. Quite a showy plant. Award of merit. Shown by the Director, R.H.S. Gardens, Wisley.

GENISTA CINEREA.—Although introduced into this country from south-west Europe many years ago, this plant is still rare in gardens. This is rather surprising as it is one of the best of the genistas. The flowers are produced in short clusters and are bright yellow in colour. Altogether it is a very desirable shrub. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

KOLWITZIA AMABILIS.—Good large sprays of this little known, rather weigelia-like shrub were shown by Colonel Stephenson R. Clarke, C.B.

PEONY MME. EMILE LEMOINE.—A large, double-flowered white sort. Award of merit.

PEONY SARAH BERNHARDT.—A beautiful double-flowered variety. The flowers are very large, deep flesh pink, paling towards the edges. It is a very desirable sort. Award of merit. Both these peonies were shown by Messrs. R. H. Bath, Limited.

RHODODENDRON CRASSUM.—A Chinese species, originally found in Yunnan by one of the French missionaries. The flowers are large and semi-tubular, rather thick in texture, white, faintly flushed rose. Award of merit.

R. ERIOGYNUM.—One of Forrest's discoveries in Yunnan. Flowers brilliant blood scarlet, but unfortunately not over hardy. Award of merit. These two Rhododendrons were shown by Mr. Lowinsky.

ROSA MIRIFICA.—A beautiful and distinct American species, native of Sacramento Mountains, New Mexico. The flowers are a purplish rose. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

ORCHIDS

ODONTOGLOSSUM DOREEN VAR. D. A. COWAN (Empress of India × eximium).—One of the best forms yet seen and well worthy of the high award given. The spike bore five large flowers, the massive segments rose tinted and profusely marked with reddish-purple bars and spots. First-class certificate. Shown by Mr. J. J. Bolton of Claygate.

CYPRIPEDIUM GODEFROYÆ LEUCOCHILUM GIGANTEUM.—A handsome flower, well above the average size, honey-yellow colour, the sepals and petals heavily marked with maroon. Native of Siam. Award of merit. Shown by Sir Jeremiah Colman, Bt.

THE YORKSHIRE GALA

THE horticultural exhibits at York, although perhaps not so numerous as at Chelsea, have during recent years been almost equal in quality and nearly as varied as those at the great metropolitan show, and this year the display proved no exception to the rule. Two large marquees were filled with exhibits brought by most of the leading growers in the land, and these proved a source of pleasure to the thousands of visitors who came from all corners of the county of broad acres and beyond. There is a vast flower-loving public in the north, and they are not slow to appreciate the early summer glory of the kingdom of Flora that is brought annually into their midst from the sunny south. York Gala comes at a time when our northern gardens have not yet put on their gayest dress. Perhaps owing to that reason we appreciate the floral banquet there all the more. There is also a difference between the typical visitor to the northern shows and the southern enthusiast. The latter needs no telling that most of the hardy exhibits will thrive in his locality, the northerner is more sceptical. He wonders if the plant he fancies will succeed where sunshine is sometimes at a minimum and mists and grey skies prevail at certain seasons. Consequently he wants to think things over before he places his orders. It may have happened that some order books have not been filled as they were expected to be, but when sowing and planting time comes round again it is possible that the exhibitor will then reap his reward. Of course, with easily grown plants, such as sweet peas, roses, antirrhinums, pansies and violas and the like, there is never any doubt about them, but there are many northern growers who doubt the possibility of success with border carnations. Let me assure them that they are quite easy to grow and there is no reason why they should not be as largely cultivated in the north as in the south.

ROSES.—I saw the roses early in the morning of the first day of the show, and they were of excellent quality and looked very fresh and clean. Both Mr. Hicks and Mr. Prince brought of their best, and on the exhibits from Hurst I noticed fine specimens of Betty Uprichard, America, Mrs. Herbert Stevens (larger and of better substance than I have seen it for many years), Sunstar, Lucille Barker, Mme. Herriot and Hoosier Beauty. Mr. Prince made a grand display with his lovely deep crimson pillar rose, Allan Chandler, which is to be distributed in the autumn, and which promises to be a decided acquisition. When I saw this shown for the first time I was not favourably impressed with it, but it appears to have outgrown its chief faults, and now seems to have developed into a desirable variety that should make as vivid a splash of colour as Paul's Scarlet Climber. Other noteworthy roses on his stand were Lady Gwendolin Colvin (another lovely pillar rose, but unfortunately only summer-flowering), Lamia and K. of K.

SWEET PEAS.—Messrs. Robert Bolton and Sons, Messrs. Ireland and Hitchcock, and Messrs. Sutton and Sons provided the bulk of the sweet peas. The former had a magnificent exhibit with rich orange and salmon shades predominating, and a number of exquisite lavenders intermingled among various shades of pink. The colour effect was brilliant in the extreme, and the general arrangement and blending of the varieties was almost faultless. The novelties Wembley, Angele, Mammoth, Supreme, Empire and Philadelphia were all in excellent condition. The first three varieties received awards. Messrs. Ireland and Hitchcock had a graceful exhibit with pillars of the leading novelties and vases of the best standard varieties. The Beacon (rich orange) and Moonbeam (lilac and bluish purple) both received awards, and a similar honour was gained with the new hybrid dianthus, which combines the best qualities of the sweet william and the pink, and which is certain to be a favourite flower of the near future.

CARNATIONS.—Mr. Englemann and Messrs. Stuart Low each had splendid examples of the perpetual-flowering types, and on the former stand there were some excellent flowers of Donald (crimson), Scarlet Iona (a very fine novelty of brilliant colouring), Vera (rose pink) and Topsy (crimson).

Mr. James Douglas had a good lot of border carnations. Wonder Clove, Bookham Flame, Virginia, Steerforth, Salmon Clove, Sabrina, E. G. Quick, Crystal Clove, Margaret Keep and Gleam were the most noteworthy.

PANSIES AND VIOLAS.—Messrs. Dobbie and Co. brought a comprehensive collection of pansies and violas of all types, and these were exhibited in vases after the English fashion. In bedding pansies, Bellfield, Sunset, Dunedin, Ophir and Ladybird were the most prominent, and James Terris, Mrs. Andrew Stevenson, Peggy Barr and Lily Stark were the pick of the violas.

ANTIRRHINUMS.—Messrs. W. H. Simpson and Sons had a beautiful exhibit of these popular flowers, and such notable varieties as Mrs. R. F. Felton, The Fawn, Lady Roberts, Golden Gem, Yellow King, Fascination, Gloria, Bonfire and Sybil Eckford were well shown.

ORCHIDS.—In the trade exhibits Messrs. J. Cypher and Sons, Messrs. Mansell and Hatcher and Messrs. A. J. Keeling and Son were well to the fore, while Mr. J. McCartney, Hey House, Bolton, an amateur, made a meritorious display. Outstanding varieties in these exhibits were Cattleya Mossiæ Wagneri, Lælio-Cattleyas Britannia, Canhamiana, Dominiana, Oncidium manacranthum, Miltonia vexallaria var. Lyoth, Dendrobium chrysotoxum superbum and Odontoglossums Gladys, amabile and Trentino magnificum.

ROCK AND WATER GARDENS.—These were a prominent feature of the Show, and many local exhibitors gained notable awards. Messrs. Broadhead of Huddersfield had a large rock and water garden with a central pool and background of conifers with primulas and mimulas in variety. Mr. P. Gardner had a pretty water garden flanked with rhododendrons and azaleas. Mr. John Winn, Moorgate, York, obtained premier award for a neatly constructed rock garden made with Ingleborough stone and a varied assortment of alpines, including ramondias, campanulas, saxifrages and armerias. Messrs. Kent and Brydon had a miniature rock garden with a background of Japanese maples. An interesting specimen in this exhibit was Enkianthus campanulatus. Messrs. Backhouse, Limited, York, were awarded a gold medal for a very neat and well arranged exhibit containing a large collection of over 150 species of alpines. The colours were beautifully blended. Oxalis enneaphylla rosea, a scarce plant from the Falkland Islands, was well shown in this display.

VARIOUS EXHIBITS.—Mr. H. J. Jones showed a magnificent bank of hydrangeas in many beautiful colours. Messrs. Sutton and Sons showed a large collection of flowers, fruit and vegetables in their usual tasteful style; the begonias and delphiniums of Messrs. Blackmore and Langdon were all that could be desired from a firm of such repute; Mr. Stark had some fine spikes of his new Campanula Ryburgh Bells; Messrs. Reamsbottom's St. Brigid anemones were very beautiful; and there were some good examples of Gladioli primulinus on the stand of Messrs. R. H. Bath, Limited. Messrs. John Peed and Son had a very fine exhibit of miscellaneous greenhouse plants, and their gloxinias and caladiums were particularly good. Two notable exhibits of fruit were those of Messrs. T. Rivers and Sons and Messrs. G. Bunyard and Co. The former showed pot-grown specimens and the latter some very choice apples in mahogany baskets. These had been stored in boxes, the fruit being wrapped in newspaper. The quality of the apples, particularly Cox's Orange Pippin, was excellent, and proves that English-grown fruit, if carefully gathered and properly stored, can be kept over a very long period. Messrs. G. Gibson and Co. and Messrs. Harkness and Sons were the leading exhibitors with collections of hardy perennials.

NORMAN LAMBERT.

NOTES FROM CONTRIBUTORS

TRIFOLIUM UNIFLORUM.

IT is rather surprising that the above plant had been allowed to die out previous to its re-introduction recently. It is a native of south Europe, and Linnæus, who originally described it in the eighteenth century, gave Syria, Arabia, Judæa, Constantinople and Crete as other habitats for it. The date recorded for its first introduction to this country is 1800. The colour was given as blue, but a variety of it introduced in 1822 had white flowers. Judging by the names given by pre-Linnæan authors, purple and white forms were known. That in cultivation at present has rosy flowers, so there is still room for the introduction of other varieties. The flowers are large and very freely produced on well established plants, so that they are quite conspicuous and pretty. The fact that they are produced singly and not in heads gives one an idea that it is anything but a clover. On account of its very dwarf habit it is well adapted for ledges near the base of the rock garden, where it would be directly under the eye. There was a fine plant of it at the Chelsea Show on the rock garden of Mr. George G. Whitelegg.—J. FRASER.

AN UNCONVENTIONAL BED OF ROSES.

ONLY in one tiny bit of my garden have I gone in for planting for effect. It is a large oval bed in a quiet corner, half surrounded at a little distance by Cupressus Lawsoniana, with the open side facing south. Here are installed Rosa Moyesii (three plants) in the centre, while all round it and below it are tangles of Rosa Hugonis and R. Willmottiæ. Below these again there are Golden Spur and Emperor daffodils, and Blue Queen and Large White (alba maxima) Scilla campanulata. I consigned the plants in their childhood to the ground in faith founded on personal observation and hearsay, and all have turned out as I hoped. The wild towering mass of Moyesii makes a grand centre, while the well flowered streamers of Hugonis and the pale rose-clad arms of Willmottiæ make an effective circle of bloom almost up to its middle. Alas! the persistent bouts of fearfully heavy rain this year so battered the primrose blooms of Hugonis that they have never been able

Digitized by Google

to open properly. It was hard lines, because plants had put forth their high-water mark of bloom and there were plenty of the smaller and more fragile-looking rosy Willmottiæ to bear them company. As I write, Moyesii looks fine. There is a goodly show of buds. Before long I hope to see a well broken up mass of its smooth, substantial-looking, saucer-shaped flowers. None of the roses is pruned, beyond cutting off branches that would otherwise have trespassed over the path.—JOSEPH JACOB.

LUPINS AT CHICHESTER.

FOR many years past, one has always associated carnations, roses, sweet peas, and so on with the well known firms who specialise in them. From now onwards, the name of Downer will undoubtedly bring to the minds of many horticulturists the famous lupins grown at Chichester.

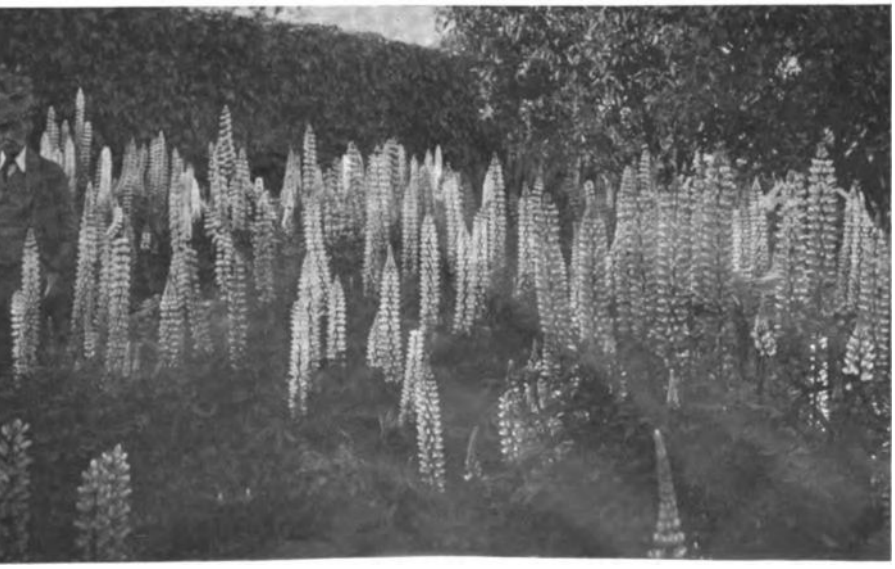
I was recently afforded the opportunity of visiting this nursery, and must confess that I was greatly impressed at the progress made in the cultivation of this particular plant. I was informed by Mr. Downer that he had been experimenting for the past twelve years, concentrating solely on the polyphyllus strain. Judging from the masses of exquisite blooms which were to be seen on all sides, he has certainly been blessed with a very fair amount of success, and it is not to be wondered at that this useful early summer flowering plant is becoming very popular.

One long bed containing over 5,000 plants, most of which were in full flower, formed a sight not soon to be forgotten. The flowering spikes were from 3ft. to 5ft. in height, and formed a veritable sea of colour, ranging from the most delicate shades of pinks and blues to the richest reds and darkest purples. Some varieties worthy of special mention were:

May Queen, royal purple (affectionately termed "Granny" on the nursery from the fact that it was raised ten years ago); Artist, delicate blue and rose; Mount Everest, pure white; Traveller, bicolor, Wedgwood blue with white hoods; Goodwood, magnificent old rose; Saxe Blue, rich blue; Downer's Delight, bicolor, old rose with crimson hood, A.M., R.H.S.; Downer's Pink Pearl, A.M., R.H.S., deep rose; May Princess, A.M., R.H.S., deep purple; Tunic, shell pink and white, A.M., R.H.S.

Among many new seedlings, I particularly noticed Mrs. Brock, a very beautiful clear rose pink, and the Countess of March, a blue and white variety in which the flowers open a pure white and turn gradually into a clear blue, giving a very pleasing effect. Both of these varieties should prove exceedingly popular when stock warrants them being put into commerce.

Another feature, quite apart from the lupins, was a very fine collection of sedums and alpines, in great variety. The writer looks forward to another visit to this very charming spot.—A. J. C.



MR. DOWNER AMONG HIS LUPINS.

A BEAUTIFUL NEW YELLOW IRIS: CHASSEUR.

THE number of yellow bearded irises in existence is not large. One of the most commonly met with is Mrs. Neubronner, intense in colouring and very floriferous, but unfortunately of short stature and small or middle sized flowers. Aurea is somewhat taller, but of paler tint; while Canari increases in height only to lose some of its brilliancy of colour. Klondyke is rather large-flowered and often attains 2ft., but has paler divisions than Mrs. Neubronner; these are striated browny violet at the base. Belcolor has creamy white flowers of fine appearance, but is too pale for a yellow; and the yellow form of I. Alberti has no particular merit other than its earliness. As for Shekinah, a variety of American origin much heard of lately, the writer has had no opportunity of observing it. There are, of course, numerous varieties of irises in which fine yellow is associated with other colours in the falls, such as Iris King, intense yellow and brilliant browny red, a fine flower; Knysma, Fro, cannæflora, Prince d'Orange, etc.; and also the variety Simile, which is probable the latest-flowering of all garden irises.

THE STRONG, RIGID SPIKES OF IRIS CHASSEUR.

With the introduction of Chasseur a great stride forward has been made. This is one of the many plants raised at the Verrières nurseries of MM. Vilmorin-Andrieux et Cie., near Paris, and was given a first prize on the occasion of the Iris Conference in London in 1922. It has since been propagated, and is now understood to be in commerce. Many points make it a first-rate variety. First, the strong, rigid spikes that stand quite erect and are fully 2½ft. in height, often 3ft.: then the large flowers, sweetly scented, of the best shape and constitution; and lastly, a colouring that is rich and attractive.

As is the case of most modern varieties, the buds are well developed and extremely showy by themselves in their last stages of development. They are of the deepest yellow colour, their base tinted reddish brown, a shade that veins the interior part of the divisions in a faint and most pleasing way when they expand. The flowers are borne five to eight on each stem and remain deeply tinted at first; then, after a few days, the centre of the divisions become paler, the margin and base retaining their rich early yellow. This gives the flower a most distinct and lovely appearance. At all stages the colour is bright. The best time, however, is during the early period of flowering.

This variety flowers in a late season, with varieties Ambassadeur, Raffet, Richard II, Black Prince, Duc Decazes, etc. As for its constitution, it is all that can be desired: the plant grows luxuriantly and produces masses of flowers.

It may be interesting to note that the plant was far less admired on its first appearance than it is to-day. It belongs to the class of irises that has to be seen in masses to make gardeners realise their worth.

Iris Chasseur, no doubt, will become a great favourite in gardens when sufficiently known, and, at the same time, probably prove of great value to the hybridiser who wants to produce a very large-flowered yellow iris with stems 4ft. or 5ft. in length, an object that many a gardener has in view.—C. L., *Paris*.

A BOG GARDEN IN A BASIN.

THE first of our miniature bog gardens was planted in an old and leaky enamel hand-basin. This was four years ago and it still flourishes. Sphagnum and other mosses are established and growing there, and among them sundews sow themselves and come up every year, and pinguiculas flower and increase. Both these plants are difficult to grow, but the bog basin seems to have solved the problem. It is kept in the open, fully exposed to the weather both in summer and winter. Since the first was started we have made several more miniature bog gardens in a variety of boxes and pans, and now have eleven, but the original one has needed no renewing. Pinguiculas are flowering particularly well this year, including some large ones which I brought from Norway in 1922. Among the plants in our various portable bogs are Loiseleuria procumbens (azalea), Silene acaulis, montias, Saxifraga stellaris (very pretty with its white flowers and red seed vessels), bog myrtle and trientalis, all brought from Inverness-shire last year; heaths, grass of Parnassus and yellow bog pimpernel brought from Goathland in 1921; Astrantia minor from Bognanco, also in 1921; and pyrolas from Norway, and many other plants which I have not mentioned. Stagshorn moss has proved very difficult to establish. We had two varieties from Norway, but they succumbed, I believe, to the use of hard water during a dry spell last summer. Stagshorn brought from Inverness-shire last autumn is still alive, perhaps because up till now it has had rain in plenty. It is fortunate that something should enjoy this wretched summer, and it is certainly pleasing to our bogs!—RUTH BICKERSTETH, *Cottingham, East Yorks.*

WAYSIDE FLOWERS OF SERBIA.

ON the fatal battlefield of Kossovo, five hundred years ago, the victorious Sultan Murad was assasinated; he has for a monument a white mosque over his tomb, standing in a silent walled garden bordered with a tangle of briar roses. Another smaller mosque is the monument of two of Murad's Turkish generals; and in the rough grass of the knoll on which this shrine stands, rounded half sunken stones mark the tombs of fallen Turks. For Lazart, the defeated Serbian Emperor, and for the soldiers of Serbia, men have not yet built a monument, but a slim white cross and the first scratchings of a garden, enclosed by barbed wire, show the place consecrated by a thousand legends of old Serbia and for which Mestrovic has designed his famous sculptured Temple of Kossovo. And meanwhile, during the five centuries of Turkish mis-rule, nature has provided the loveliest of memorials, for it is the blood of the heroes—so legend admirably says—which accounts for the redness of the once white peonies of Kossovo. Among low bushes of white hawthorn and white rose in flower the peonies spring up in clumps. Thousands on thousands of them, not weighed down by being monstrously doubled like their garden offspring, but holding their blood crimson cups erect in the sun. I do not remember a lovelier sight, in the way of wild flowers, than these peonies—"bon-jours" the people call them—in their setting of white-blossom on Kossovo down. The remote snows of Shar Planina, blurred by heat, remind one of cool heights as one walks down there on the rolling sun-burnt plain, choosing each bon-jour one comes to as the finest and crimsonest among its neighbours. In some places, instead of hawthorn, the setting consists of white poet's narcissus.

To see these Peonies growing in natural conditions may give one a fresh idea as to how to use them in the garden. The peony in question is, I take it, the single type of P. officinalis; it grows and flowers profusely even in that poor soil in full sunlight, where it must get roasted, burnt up, long before the summer is over. I have noticed that white flowers, such as the white Camassia Leichtlinii and white irises, make good company for the single scarlet peonies, such as Fire King. Having seen the peonies of Kossovo I must try growing other white flowers with them. There is no doubt, I think, that these cup-shaped single species, such as officinalis, arietina, Whitleyi and Mlokosewitschi, have many advantages over the double garden sorts, effective as those are.

Another lovely sight in the neighbourhood of Kossovo is the purple annual delphiniums and the purple Verbascum (Wiedmannianum?) which grows thickly among the blue-green blades of the barley. This verbascum, by the way, surely deserves to be more commonly planted; it is a delightful plant to associate with other violet and purple flowers in the border, such as Thalictrum aquilegifolium atropurpureum and Iris Alcazar.

Will someone tell me about the beautiful white poppy that is fairly common in the neighbourhood of Belgrade and which I found in profusion at one place on the road between Kraljevo and Kaska; it seems to be simply a white form of the scarlet field poppy. Where I found it it grew on rock faces and screes, the flowers solitary and nodding, with dark centres. It has something of the grace of Farrer's beautiful Meconopsis quintuplinervia. I noticed in one or two places a variant form more or less stained with pink, which is presumably a cross with the scarlet species.

One of the strongest impressions of travel in Serbia in May is the scent of the acacia; out of every hedge, in every copse, over every garden wall, this delightful tree hangs, its scented wistaria-like trails more beautiful in colour against the unclouded blue sky than even laburnum would be.

I had not time to hunt for flowers in any remote places; I could not get up into those inviting Albanian mountains, partly because, though I might I suppose have found say Ramondia Heldreichii, I should probably have been found myself by picturesque but none the less real brigands. So these notes can have no interest to the botanist. I can only say that if a traveller goes through Serbia in May he will find, besides a delightful and friendly country, golden drop (onosma), burning bush (dictamnus), smoke bush (Rhus cotinus), and lithospermum by the wayside, plumes of saxifrage on shady banks, and a harvest of dog-tooth violet seed in the woods. Quite common things, you say. Well, go and see those peonies on Kossovo, no common sight.—A PAINTER.

A LETTER FROM NAIROBI.

IT may interest you to know, in connection with your statement in THE GARDEN, April 26th, page 274, regarding annuals for Nairobi and your apparent ignorance of our very important country, that we have two societies in connection with horticulture, the most important being the Kenya Horticultural Society, which is affiliated to the Royal Horticultural Society of England.

In connection with this Society we run what we imagine to be a most important part of our work, viz., a gardening page in the local paper, the *East African Standard*, in which we endeavour to give newcomers the benefit of our experiences in the realms of horticulture. There are many beautiful gardens in Nairobi, and it would be easier to give you a list of what will not grow well, rather than a list of the flowers that do splendidly—for their name is legion. Take the Colony as a whole, it is a gardeners' and botanists' Paradise. At the coast you get the glaring hot sun of the Tropics with a heavy rainfall, and from there through every degree of temperature and climate till you pass the alpine belt climbing Mount Kenya and reach the snows. I have had over sixteen years' experience of gardening in this country. There are wonderful wild gladioli, for instance, crinums, moræa, orchids, thunbergia, delphiniums, senecios, verbascums, violets, tritomas, etc., to make anybody's horticultural mouth water, and for the most part the country is botanically unexplored. Not many months ago I found a new mesembryanthemum and a most glorious lissochilus.

I find your paper very interesting and always look forward to its arrival on mail days.—(Mrs.) LUCY M. LANGRIDGE.

FLOWERING LILIES.

MAY I beg a corner of your space to ask if those of your readers who have good flowering specimens of any of the following lilies, will kindly communicate with me at 2, Albion Street, W.2. I am in need of a photograph of a representative specimen of each lily for a Dictionary I am preparing of the genus. Concolor, Kelloggii, japonicum, maritimum, philadelphicum, pomponium, rubellum, tenuifolium.—A. GROVE.

A GOOD WOODLAND COLUMBINE.

THE ideal woodland columbine must possess, in addition to a pleasing colour and grace in flower and foliage, a trustworthy constitution. It should, for preference, be a true perennial, one that will stand up to life among woodland herbage in sun or shade, sow its own seedlings and disdain to intermarry with others of its genus. All these attributes can be claimed by Aquilegia formosa, a form of A. canadensis, which latter is to the former what water is to wine. Our stock of this charming thing came from British Columbia (Vancouver Island, to be more exact) many years ago, and it has ever since been one of the most charming plants of the woodland garden.

A. formosa grows about 2ft. in height, commencing with a tuft of broad-leaved foliage in early spring of that peculiarly soft yet vivid green of the young fronds of a maidenhair fern. Above this rise in May the flower-stems, which, branching freely, bear at their tips elegant, short-spurred flowers of large size in a most alluring orange-scarlet with rich butter yellow petals. These lovely blooms are not only a more delightful colour than those of canadensis but they are broader and ampler, and their poise on the slender stems gives the whole plant a lighter, more refined loveliness. A. formosa has become naturalised in our light woodland loam, and while the stray little colonies of plants which crop up here and there are never out of place, they are rarely so charming as when associated with native ferns in the dappled light of thin deciduous trees.—A. T. JOHNSON, *North Wales.*

THE PROPAGATION OF CHOISYA TERNATA.

IN my garden I have no difficulty in increasing Choisya ternata. I just turn a branch down on to the ground, press it in and put a stone on it, and in a few months it strikes. Often it roots of itself without any help.—D. E. BULWER, *Sussex.*

PRIMULA LADY THURSBY.

IN the report of the Royal Horticultural Society's meeting of May 13th and 14th (page 360), you comment on my Primula Lady Thursby. Your remark as to its not being a hybrid is quite correct. It is true pulverulenta and I have been working for several years to obtain a fertile pink plant. The award card was filled in wrongly. I sent up a hybrid primula as well and this was put on the award card, and in correcting the name, the word "hybrida" was not erased. The word "pulverulenta" should have been inserted in its place. There is a vast difference between a pure bred plant and a hybrid.—G. H. DALRYMPLE.

LEEKS AND ONIONS.

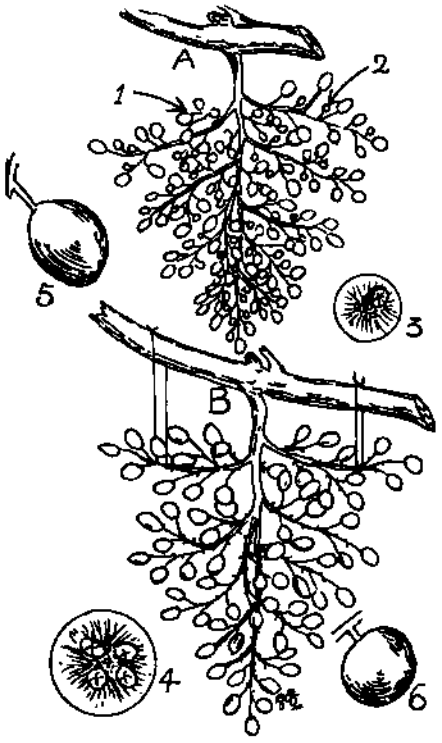
Specimens that are being grown for exhibition at the autumn shows should be encouraged to make as much growth as possible from midsummer to the end of July—that is growth of stem and leaves. The bulbs, in the case of onions, will begin to form freely towards the middle of July and, according to variety, locality and soil, will mature ready for harvesting from the end of August to the beginning of October. Even where fairly dry soils obtain and in the absence of rain, artificial watering should be avoided as much as possible. Twice each week the surface soil should be hoed with a Dutch hoe to create a dust mulch, and early in August a surface dressing of 4oz. of bonemeal per sq. yd. covered with one 2ins. thick of rotted manure will prove very beneficial. I do not recommend ordinary surface watering, nor feeding in this way, for onions and leeks, but at a distance of 2ft. apart, in the centre between two rows, make small holes 16ins. deep and fill them with diluted liquid manure twice a week. The general treatment should be such as to induce the roots to go deeply during dry weather and not to bring them to the surface. Such stimulants as sulphate of ammonia and nitrate of soda should not be applied by the inexperienced, as the slightest overdose would cripple the tender, fleshy roots. The blanching of early leeks should commence at the end of June by placing pure sand round the base.

THE COLD FRAME IN SUMMER.

The cultivator rarely experiences any difficulty in filling the frame from October to May. But throughout the summer months many frames remain empty except for the weeds which not only fill them but depend from the sides, flower, seed and stock the borders near by with young, undesirable plants. All who now plead guilty, should at once clean out the frames, put in nice beds of rich compost and plant ridge cucumbers or vegetable marrows. These would be exhausted in September. But the cold frame, especially the movable one, is an ideal shelter for such plants as cinerarias, primulas, calceolarias, cyclamens, schizanthuses, winter-flowering stocks, solanums, young fuchsias, salvias, etc. The permanent fixture frames should be shaded judiciously throughout the summer, the movable ones may be placed to secure a north aspect. In the case of vegetable marrows and ridge cucumbers the haulm should be allowed rather free growth as that portion outside the structure usually bears more and finer fruits. In northern counties these frames are more generally used in the summer, and in them choice alpines, violas and similar plants find a comfortable home. In some gardens which may lack walls or fences, on the north side of which Indian azaleas may be placed during the hottest days of the year, the walls of a frame may act as a protection to the pots and roots from the sun. Daily syringing in sunny weather promotes a healthy growth and keeps down red spider and thrips.

THINNING GRAPES.

When the cultivator possesses a good crop of nicely shaped, clean bunches the work of thinning out the berries is a very



pleasant one. The bunches of all grapes subjected to heat were thinned a few weeks ago, but there are many bunches in cool structures that need attention in this way, now. Fig. A shows at No. 1 the right kind of berry to retain, and at No. 2 the small ones that should be removed. Fig. B shows the bunch properly thinned and the shoulders neatly tied to the stem above. More berries may always be safely left near the top of the bunch than at the bottom—the point. The three end berries on all berry-bearing branches of the bunch should be retained if they are well stoned. No. 3 shows a badly set berry containing one stone; No. 4 a well set one with full complement of four stones. More berries may be left in a bunch with oval-shaped berries possessing long foot-stalks (No. 5) than in the case of round berries with short foot-stalks (No. 6). The berries should not be rubbed nor handled.

FOWL MANURE.

Where, ten years ago, a dozen fowl houses could be seen by a passer-by in one district, fifty may be seen to-day. The droppings from the fowls in these houses form very valuable manure for general use in the garden. Here and there a poultry keeper knows this and takes proper care of the droppings from day to day; but I am afraid the great majority do not realise how valuable this manure is. Pigeon manure is of even greater value, possessing more than double the quantity of nitrogen, about double that of phosphates and potash respectively. For gross-growing vegetables one pound per square yard is a suitable quantity to use. I have seen enormous crops of tomatoes and potatoes grown as a result of judicious applications, and from personal experience I can recommend it. For tomatoes 8oz. per sq. yd. is sufficient, prior to planting and mixed with loam for surface dressings. One ounce per 10in. pot and mixed with fibrous loam, is a right quantity for top-dressing tomatoes and chrysanthemums—the latter after the buds are taken. But the manure should be kept quite dry and spread out in a thin layer in a cool, airy shed. Before using it should be broken up as finely as possible. If it is placed in a heap outside and allowed to get saturated, the fermentation is rapid and more than half its manurial properties wasted.

STOCKS FOR EARLY SPRING FLOWERING

All who possess a greenhouse or a conservatory should grow a batch of stocks in pots for furnishing such structures in the early part of the year. Few, indeed, are the plants that are more easily grown and managed generally. A dozen plants will fill the house with perfume and add also to the display of colour, as carmine, rosy carmine, white, light blue, golden buff and salmon pink are all available. The seeds should be sown late in summer in pots or boxes filled with a sweet compost of fibrous loam, leaf-soil and old mortar rubble, as stocks thrive where there is a small quantity of old mortar in the soil. The seedlings are best raised in the open air, as there should not be any coddling, but protection from much rain is advisable. Sow the seeds thinly and transplant the resultant seedlings singly in small pots when each possesses two rough leaves. The repotting should be attended to in due course till the flowering pots, 6in. or 7in. ones, are filled. A little bonemeal at the final potting is all the stimulant required. Frame treatment from October to Christmas, then greenhouse till the flowers begin to lessen. The Beauty of Nice Mammoth stocks are among the best ones to grow.

GEORGE GARNER.

Digitized by Google

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Winter Crops.—Such plants as kales, savoys, winter and spring broccoli should be planted without further delay, making the ground fairly firm before planting. Allow plenty of space between the rows, and keep the hoe at work when the plants are established.

Spinach Beet.—Make another sowing of this useful vegetable in lines 1ft. apart, and finally thin the plants to 8ins. in the rows. A sowing of the prickly or winter variety of spinach may also be made.

Peas.—Most growers try to keep up a supply of peas as late as possible, and although a late variety, such as Late Queen, may succeed, it is much safer to depend on the early varieties, which do not take so long to mature. Shallow trenches with a layer of manure in the bottom are recommended, and if the soil is dry at the time of sowing it should be saturated with water a few hours before the seeds are sown, otherwise they will remain dormant until it rains. Stake early crops before the haulm bends over, and use the hoe freely between the rows.

Vegetable Marrows.—The fruits should be removed from the plants when they have attained a reasonable size, or the plants will cease to be productive. Regulate the growths and remove the points occasionally. An application of weak liquid manure once each week will help the plants considerably.

THE FLOWER GARDEN.

Pinks.—These charming flowers are always admired, and to maintain strong flowering clumps it will be necessary to propagate a few plants each year to keep up a young healthy stock. There are now plenty of cuttings or pipings on the old plants, and they will root freely if placed in a cold frame containing a layer of sandy soil. Shade them from strong sunlight and lightly spray the cuttings once or twice daily according to the weather. When the cuttings have rooted the lights should be removed.

Chrysanthemums.—For autumn decoration these are most valuable, and the plants should be staked before the growths bend over or they will be useless for cutting. Stout bamboo canes should be employed, and the shoots tied loosely to allow them plenty of space to develop. Keep the plants clean and afford a light mulching of decayed manure. Pinching the shoots should cease.

VEGETABLES UNDER GLASS.

Tomatoes.—An autumn supply of tomatoes is often desired, and where accommodation can be found for the plants later on seeds should now be sown. Sow the seeds very thinly, and they will germinate readily in a closed frame. Keep the seedlings close to the glass, and pot them off singly as soon as possible. These plants should be grown hard during the next few months, and when established they may be fully exposed both night and day. Sturdy plants always give the best results. Plants raised about this date will also be suitable for planting in houses or pits from which an early crop has been gathered. Seedlings in their early stages of growth ought not to become pot-bound, and good fibrous loam with a little old mortar rubble constitutes a suitable rooting medium. Best of All and Princess of Wales are reliable varieties.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Brassicas.—As crops of cabbages and cauliflowers advance in growth they should have the earth drawn close up to the stems on either side of the lines. Where blanks occur from one cause or another among vegetable crops they should be filled with other plants. Sprouting broccoli and savoys may still be planted.

Seeds to Sow.—Carrots of an early maturing variety may be sown on ground from which early potatoes have been lifted. A small sowing should be made of the following varieties of cabbages: Edinburgh Market, Sutton's Flower of Spring or Pringle's Imperial. Set the young plants out when large enough. These plants should come in for cutting in the early part of next year. Kidney beans, parsley and Spinach Prickly Seeded may also be sown.

THE FLOWER GARDEN.

Herbaceous Borders.—As plants pass out of flower the old flower heads should be cut off—except if seed of some scarce or special plant is required. This will not only add to the tidiness of the borders, but in some cases a second floral display may be obtained from plants, such as lupins. This year these handsome plants—including a few which we moved somewhat late—have flowered well, and except for an odd plant or so bud dropping on the white-flowered plants is negligible.

Narcissi.—Where the beds have become overcrowded the bulbs should be dug up and separated. The best bulbs should be kept and replanted in lines 1ft. apart, allowing 4ins. to 6ins. between each bulb in the lines according to variety. This should be done as soon as the ground has been dug and enriched with old manure or leaf-mould.

Pinks.—If a further increase or a young stock is required, cuttings or slips should be secured now from the old plants. Young shoots 3ins. or 4ins. long should be selected and simply torn from the old stems. They should be dibbled 2ins. or 3ins. apart into sandy soil made quite firm in a cold frame. After being thoroughly watered the frame lights should be put on and kept closed for two or three weeks. The cuttings should be occasionally sprayed and at all times shaded from bright sunshine until rooted.

THE HARDY FRUIT GARDEN.

Strawberries.—Those who have not tried what is called the American method, but which I practised before ever hearing of such a name, will find it a fairly convenient way of providing a stock of plants for early planting. At this time we select and sever from the plantations the runners we require; these are set out in lines fairly close together in a cold frame and receive a thorough good watering. The frame is kept closed and the runners occasionally sprayed, and kept shaded from bright sunshine for two or three weeks, and gradually hardened off.

FRUITS UNDER GLASS.

Melons.—Most growers know the tendency melon plants have of decaying at the neck, and often going off altogether when the plants are a good size. Various things are tried to check decay, such as lime or powdered charcoal, and even a little styptic may be used, and if conditions are favourable it will prove quite effective.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Campanula Medium and its numerous varieties when grown in pots are very useful for conservatory decoration during the spring. To obtain plants for this purpose seed should be sown in boxes at this time, standing them in cold frames, and keeping them shaded until germination takes place. When large enough to handle the seedlings should be pricked off into boxes and when the plants are large enough, planted out in the reserve garden. During the autumn they should be lifted and placed in pots, so that they can be wintered in cold frames. Early in the year they will require a shift into larger pots, 8in. being a suitable size to flower them in.

Campanula persicifolia and its fine variety, Telham Beauty, are also very suitable for pot work. If not already done strong offsets should be secured and planted out in the nursery garden where they should make good plants for potting up during the autumn. They may be stood at the bottom of a wall for the winter, or in cold frames, but the lights should be kept off whenever the weather permits.

Richardia Elliottiana, E. Pentlandii and the hybrid Mrs. Roosevelt, after having finished flowering should be kept going until the foliage shows signs of dying down, when water should be gradually withheld. When dried off they may be stored for the winter in their pots, or they may be turned out and stored in dry sand. Good strong tubers are essential for successful flowering, and RR. Elliottiana and Pentlandii may be raised from seed, treating the young plants in much the same way as hippeastrums.

Gloriosa Rothschildiana is generally regarded as requiring stove treatment, whereas it is really much better in an ordinary greenhouse, the flowers under cooler treatment being a much better colour and lasting longer. The tubers are best started in a warm house, but afterwards should be grown in an intermediate temperature until they come into flower, when they may be removed to the conservatory. This plant, of course, should now be in flower, and where stocks exist the plants should be tried in the greenhouse. This species sets and ripens seed freely under cultivation, and thus affords a ready means of increase.

Bougainvilleas are very useful for conservatory decoration, either planted out or grown in pots. B. glabra Sanderiana being the most suitable for pot work, as it flowers freely in a small state. In addition to this we now have B. Mrs. Butt. It is the brightest of them all, and the flowers may be described as a brilliant cerise-red, and young plants will produce flowers in 48-sized pots, which is certainly unusual for a bougainvillæa. Cuttings made from half-ripened twiggy shoots root readily in a close case with slight bottom heat. Stocks of this plant are now in the trade and it should prove very useful for decorative work.

Clethra arborea, with its beautiful white lily-of-the-valley like flowers, is very suitable for a large conservatory, either planted out, or grown in tubs. This plant is easily propagated at this time by means of half-ripened shoots, which root readily under a bell glass in a cool house.

J. COUTTS.
Royal Botanic Gardens, Kew.

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

About Rose Shoots (R. D.).—The rose bushes are not diseased. The shoots sent are quite healthy—normal. But owing to the recent wet weather the young shoots are sappy, and the youngest leaves curl a little in the sunshine. If the soil in the particular bed is naturally more moist than in the others it would conduce to the soft growth.

Peonies Unsatisfactory (M. H. A.).—It is very likely, judging from the appearance of the stems, leaves and buds sent, that they were frozen at an early stage of growth and exposure to the sun while in that state, caused the mischief. The plants would be strengthened if they occupied a richer rooting medium. This could be given them after October. In open, sunny positions, plants require judicious feeding directly the flower buds are formed.

Lilies of the Valley and Irises Unsatisfactory (Countess).—The lily of the valley has been attacked by the fungus (Ovularia elliptica). When the leaves die naturally, gather them up but do not force them away from the crowns. Clean the surface soil of all foreign matter and replace with a layer, nearly 2ins. deep, of sweet leaf-soil on a dusting of powdered sulphur. The trouble may not occur again. If any crowns are to be replanted do the work at the end of February. If the leaves are those of the flag iris, they appear to be suffering from too much moisture, as a well drained soil is essential. There is, not, otherwise, any apparent reason for the present appearance of the leaves. A rich soil and open sunny position is best for these; and a deep, moist soil in a sunny position in the case of Iris Kæmpferi.

English Irises, Plants Dying (M. T. P., Devon).—Judging from the specimens sent by our correspondent we think the trouble comes from the soil. The latter is too moist for them this year, the roots having perished wholesale, even the bases of the bulbs are rotting. Although perfectly hardy these plants require a loose, sandy soil to grow in, then they may be left undisturbed for a number of years. Such a rooting-medium should be prepared for the plants in due course.

Black Spot in Roses (J. E. T. Y.).—The black leaf-spot, a troublesome fungus, is unfortunately, very common. All infected leaves should be removed as soon as the spots are noticed and before the fungus has fruited. Then use a solution of sulphide of potassium at the rate of half an ounce to a gallon of water, thoroughly moistening all the foliage. Regularly clean up and burn affected leaves, and others, that fall. The Lilium plants are probably affected by canker owing to too much moisture in the soil. In due course lift the bulbs, dry in a cool shed, well cover them with powdered sulphur, shaking it into the scales and remove the roots. Store in a cool, dry shed and replant in September and in a fresh position. In the meantime, deeply dig the soil and add rotted manure to the lower portion.

FRUIT GARDEN.

Peach Tree Leaves Diseased ("Puzzled").—The leaves sent by our correspondent are badly blistered. The fungus Ascomyces deformans has had weather favourable to its spreading this season. The fungus increases among the cells in the internal portions of the "blister" and comes to the surface when its fruit is ripening. There should be old lime rubble or lime mixed with the soil. The latter should be maintained in an even state of moisture while light protection from the east winds is beneficial, but spraying in due course is the most important item to attend to, and thin training of the young shoots combined with cleanliness.

About a Fig Tree (E. F.).—It is very difficult to identify a fig from a leaf only. Judging from the specimen sent by our correspondent, it resembles that of the variety Precussata. We doubt very much the possibility of the tree being the result of a seed sown except from a fruit ripened abroad, as seeds do not ripen outside in this country. As a small fruit has been seen on the tree it is possible that more may form; if so, pinch off the end—tip only—of the shoot beyond the fruits when the latter are quite small, and send a specimen or two for examination.

Peaches Unsatisfactory (G. A.).—Peach trees should be so disbudded in the spring and stopped—regarding lateral shoots in the summer—that very little winter pruning will be necessary. Undoubtedly, the roots are crippled and should be attended to next autumn. Checks, from roots or temperature, or both, have caused the fruits to drop.

About Gooseberries and Poplars ("Limington").—The gooseberries are badly affected by the gooseberry mildew fungus, and all the trees, roots included, should be uprooted and burned. A new position for a fresh plantation should be selected. The old soil should be dressed with gas lime, 6 oz. per square yard, next autumn. The poplars are not diseased, but simply damaged by storms.

Apple Branches Diseased (J. M.).—The tree from which the branches were taken is in a bad state of health; its roots are in an unsuitable soil, the best soil for the apple being a good deep loam on a well drained subsoil. The youngest leaves have been infested with black aphides, and other insects which we do not recognise, and, furthermore, the foliage is suffering from leaf-curl, partly caused by the aphides and partly by fungus. The branches are slightly cankered, and if the trees are old it would be better to destroy them and plant young ones next autumn. If not old, renovate the trees next winter by giving attention to the roots. The best course would be to uproot them.

Young Pear Fruits Damaged (R. J. G. R., Berks.).—The young fruits sent are attacked by a grub, Tortricina asiaphilus, which eats fruits, leaves and very young stems. The fruits are also affected by the fungus Fusicladium dentriticum. All affected leaves and fruits should be collected and burned and also the leaves in the autumn, afterwards spraying thoroughly with Bordeaux mixture, and a second time, in the spring, before the buds burst.

FRUITS UNDER GLASS.

Grape Vines Unsatisfactory (A. J.).—Both the bunches and the leaves are very badly mildewed. Flowers of sulphur, freely sprinkled on the leaves, would lessen the trouble but not remedy it completely. It would have a very unsightly appearance used on the bunches. "Abol," used as per instructions, would cleanse the berries of mildew, but it destroys the "bloom" on them. Mildew does this, too, and renders the fruit unfit to eat. Too wet or too dry borders, irregular ventilation at the wrong time, and cold draughts all causes mildew to spread on the vines. If the roots are too deep in the border it may be advisable to renovate it next winter.

THE KITCHEN GARDEN.

Peas Dying (R. C. D.).—The "eggs" our correspondent refers to are nodules on the roots of the plants and are quite healthy. The plants succumbed to attacks by small slugs. In future treatment use old soot freely and dry lime moderately around, not on, the plants. The plants feed through the presence of the nodules.

MISCELLANEOUS.

Names of Plants.—W. T. H., Worthing.—Sagina apetala.——B. C. T., Wilts.—1, Lonicera sempervirens; 2, Jasminum humile.——B. M. C., Shropshire.—Lilium pyrenaicum. This species is quite hardy.——E. E. B., Hawick.—Lonicera Ledebourii.——N. W., N. Wales.—Rosa spinosissima flore luteo pleno, the "Double Scotch Rose." This rose does not require pruning.——H. C., Sussex.—1, Corokia Cotoneaster; 2, Davidia involucrata.

A SERVICE BUREAU

WE are receiving an increasing number of letters from the Colonies and from countries abroad asking for information and advice upon matters horticultural, so it has been decided to start a regular Service Bureau. The objects in view are as follow:

(1) To assist our readers abroad to gain special information upon branches of horticulture with relation to their particular locality and climate. We have correspondents throughout the world, and so have every opportunity of obtaining information from the best sources.

(2) To advise readers about the suitability of plants grown in the British Isles, including fruit trees, when transferred to different parts of the globe.

(3) To assist readers in obtaining seeds, plants and horticultural sundries from the best sources in England. Readers, however, must realise that we are not responsible for customs regulations in different countries abroad. We cannot guarantee that plants and seeds will not be held up by the various customs authorities, nor can we guarantee that plants will arrive in good condition, although every effort will be made by firms and individuals, to whom we hand on orders, to despatch suitable plants and to secure adequate packing.

(4) To place overseas readers who may be enthusiasts in one particular branch in horticulture, in touch with similar enthusiasts in all parts of the world.

(5) To assist them in all things appertaining to horticulture and arboriculture to the best of our ability

This service is free.

Although this Bureau is primarily intended for readers overseas, yet there is no reason why subscribers in the British Isles should not make use of our services. Naturally, there is information which is not so necessary in this country and yet is of assistance to those who garden abroad. Horticulture in this country has been in a flourishing state for many years, the horticultural trade has been organised to supply people at home with what they require, while there are dozens of flower shows both in London and in the country where traders show their wares and gardeners can see what a plant looks like. These are all points of which lovers of gardens abroad, particularly in new countries, are not always able to take advantage, and it is information of this kind that we hope to supply. On the other hand, we feel that our readers in the British Isles do not make nearly enough use of THE GARDEN. We are here to supply information, either through the columns of the paper or by direct correspondence. As this is a species of mutual benefit association between the paper and its readers, in our case we hope to gain by an even more rapid increase in circulation and in added response to advertisements. We also hope that readers will mention THE GARDEN when corresponding about plants or merchandise mentioned in the advertisement columns.

In addition, we are anxious to start a reference file of all our readers, both at home and abroad, who are interested in any particular kind of plant or class of gardening. We are sometimes asked by subscribers to put them in touch with fellow-enthusiasts, and we feel that this desire for interchange of views is worthy of every assistance on our part. By this means not only can information be gained but particular plants exchanged, for it is in this way that plants can be circulated with a knowledge that they will be appreciated and cared for. We would therefore ask all readers who are interested in one particular branch of horticulture to send us their names, addresses, and specialities, for indexing.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

SUMMER BORDERS, by Miss Gertrude Jekyll.
AVENUES, by Professor Augustine Henry.
COTTAGE AND STATION GARDENS.
ROSES IN OLD RECEIPT BOOKS.
REPORT OF THE ROYAL HORTICULTURAL SOCIETY'S SHOW AT VINCENT SQUARE.

Digitized by Google

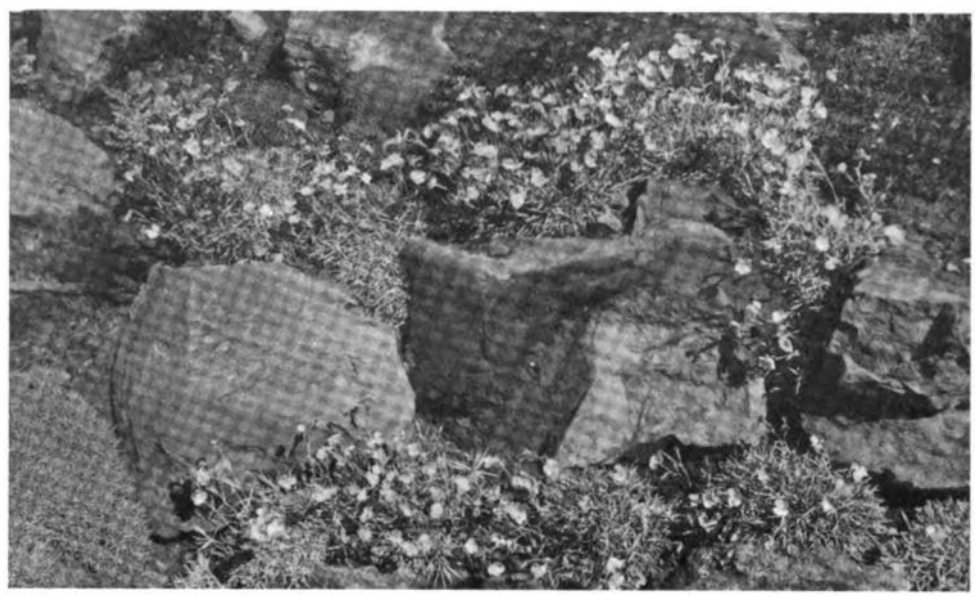
SUMMER COLOURING IN THE ROCK GARDEN

BY DR. LLOYD PRAEGER.

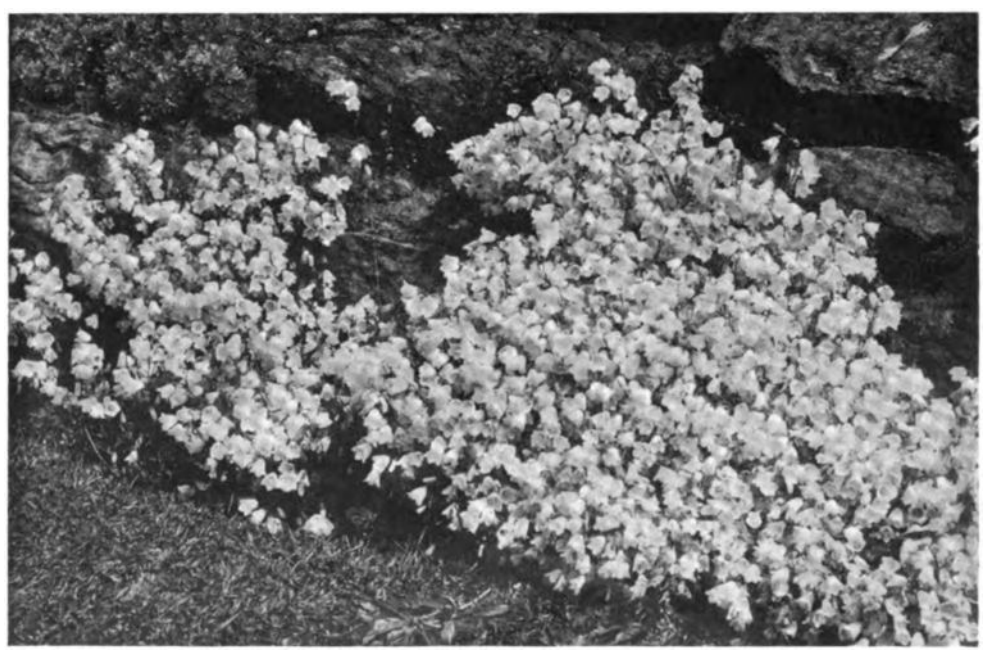
MANY GARDENERS FIND A DIFFICULTY IN KEEPING THEIR ROCK GARDEN FILLED WITH A SUCCESSION OF BLOOM DURING THE SUMMER MONTHS. THIS ARTICLE GIVES SUGGESTIONS FOR A GOOD BEGINNING.

THE subject of the present notes is not of my choosing and what I have to say about it may be thought somewhat unorthodox. But if my readers do not agree with me, so much the better. Progress lies that way rather than in acceptance of ideas only because one is rash enough to put them in print. Among the points which I should like to discuss, and on which I should be glad of criticism, are these. (1) To what extent is a blaze of colour the main object to be aimed at? (2) Is it good to mass plants which do not naturally grow in masses in order to enhance their colour effect? (3) How far is the inclusion of annuals and of "florists' flowers" justifiable for the same object? These are questions in garden æsthetics rather than in practical gardening. You want to produce effects which satisfy your sense of the beautiful and the appropriate, and everything depends on what you consider beautiful and appropriate in the rock garden. Now, rock gardening differs from many other departments of horticulture—from the greenhouse, the arboretum, the rose garden, the herbaceous border—in this: that its practice admittedly involves an attempt to imitate Nature. The books on the subject are full of instructions how to lay out the ground "naturally"; how to place the rocks "naturally"; how to arrange the plants "naturally." The desire to imitate Nature will, I think, be admitted; and the implications involved in this admission are far-reaching, and include answers to the questions which I have propounded. Our rock gardens should reproduce—subject, alas! to the many restrictions imposed by climate, soil and practical considerations—the best bits of natural rock garden of the Alps or Pyrenees. Of course, purism may easily be carried too far. I do not suggest, for instance, that only species which are found growing together on a mountain range should consort with each other in the garden, as is done in the great rock garden at Dahlem. This arrangement is of much interest to the botanical geographer, but most gardeners will not go far wrong in mixing together species from any part of the world—*provided they are rock plants*. That is, I think, where a sense of appropriateness, of propriety, should make itself felt. The proviso gives us ample scope, goodness knows! For the term "rock plant" is very wide; indeed, the only definition that seems to cover it is *a small perennial*, be that perennial herb or shrub.

If we observe the natural rock gardens which are to serve as our guide in the construction of artificial ones—be they Norwegian cliffs, Alpine moraines or Karst limestones—we will note that their pleasing features do not arise solely from their brilliant flowers. The form of the plants and the colour of their leaves and stems are very important contributory features. This supplies a strong hint by way of answer to the first of my questions. Again, annual plants are in these places usually few and not important from the decorative standpoint. To increase the wealth of summer colour in the rock garden by gaudy splashes of lowland southern annuals seems to me inappropriate and not even pleasing, as it tends to spoil the quieter tones of the more legitimate occupants. Even for late summer, when the rock garden is notoriously in want of brightening up, I think the use of miscellaneous annuals shows a lack of appreciation of the true *metier* of the rock garden.



USEFUL FOR MASSING. DIANTHUS CAESIUS.

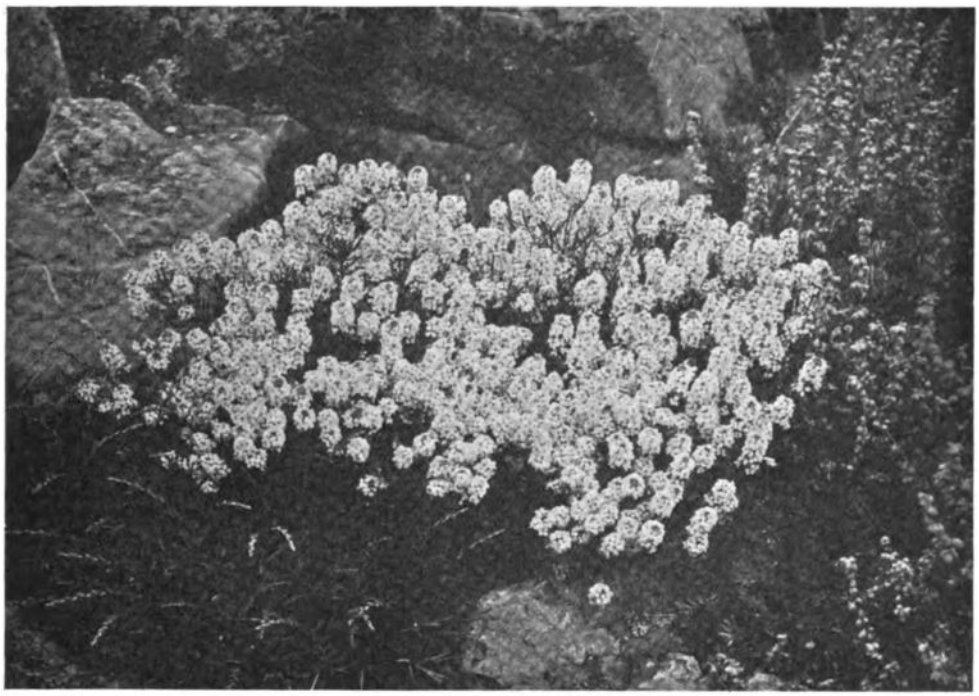


ONE OF THE MANY FORMS OF THE DAINTY CAMPANULA PUSILLA.

Digitized by Google

Besides, with care and thought the rock garden can be made very pleasant even in late summer and autumn; there are many interesting late-flowering rock plants, though mostly of subdued tone, and plenty of possibilities in the way of foliage effects.

Lastly, I think the grouping together, as in a bed of lettuces, of many specimens of plants which in Nature grow singly,



ÆTHIONEMA PULCHELLUM SHOULD HAVE SUN AND A LIGHT SOIL.

in order to produce a mass of colour, is generally not desirable. The plant which naturally grows singly in the open has often a graceful and characteristic outline—figure, if one may call it so—which is lost if planted massed. Take phyteuma, for instance, with its stiff or spreading straight stems rising from the graceful tuft of arching leaves. Campanula Tommasiniana and C. Raddeana are other examples of what I mean, and most subshrubs and shrubs. On the other hand, plants which are inclined to straggle when in flower, like the larger potentillas, usually grow naturally among other vegetation, where the weak stems obtain some support; to plant a group of them together is quite allowable, and enhances their effect.

The questions set at the beginning having been now in some degree answered, and the point of view made clear, it remains to take a rapid view of a few of the plants available for the production of summer colour in the rock garden. By "summer," early summer is understood—leafy June. The months which follow are more difficult, and merit a separate chapter some day. June in the rock garden differs from May mainly in that a much greater number of plants are in bloom, with a corresponding increase in variety of form and tint. At the same time June seldom offers masses of colour equalling those of the preceding months, for few plants indeed are so free or so floriferous as those great stand-bys of May, Alyssum saxatile, Arabis albida, Aubrietia deltoidea, and the white and red mossy saxifrages. Only the campanulas of the Portenschlagiana group, a few creeping veronicas, the rock roses, some of the pinks and a few sedums, like album and sexangulare, can vie in mere mass of colour with these May champions; but the June plants offer much more variety of tint, including some very precious blues, and the wonderful range of shades found in helianthemum, running from white and yellow through pink, orange, salmon and apricot to scarlet and crimson. For big splashes of blue the good forms of Veronica Teucrium dubia are very hard to beat—this common plant is a real treasure. Blue-purples are supplied in abundance by the campanulas, not only the large sheets of Portenschlagiana and its allies, and the imperial purple of pulla and its associates, but the pale tints of garganica, the dainty pusilla with its many forms, the fairy-like arvatica and many others. Later than these, the numerous rotundifolia section—the true harebells—come in when colour is beginning to wane, and are doubly welcome on that account. It is easy to brighten the June rock garden with the innumerable garden forms of pinks, but the wild species are so pleasing that this doubtful expedient is uncalled for. For masses of colour we have D. suavis (white), D. cæsius and D. plumarius (pink), and for general purposes a lovely array of species from 3ft. forms of D. Carthusianorum to 3in. D. subacaulis, with D. neglectus, which is easy and several others which are not so, where a spot of intense colour is desired. Another invaluable group when you wish colour laid on with a large brush, so to speak, is the creeping thymes; from white and pink up to the intense crimson of T. Serpyllum coccineum. Then the lithospermums and their cousin moltkia give very precious masses of blue—if they will grow with you. On my own light limy soil I find L. intermedium much the easiest—a very valuable plant.

The erodiums, which came in in May, are still in full bloom in June, and are very desirable, not only for their pleasant pink flowers, but for their graceful green or greyish foliage. The silver saxifrages are at their best, and in a year of good flower they make a fine display. They are too well known to need further comment here. Among the mossy section two excellent plants which flower in summer are S. trifurcata and its neighbour ceratophylla. Both form large cushions of stiff dark green foliage and bear a great wealth of china white blossom on dark wiry stems. Some of the later genistas are June flowerers and give good masses of yellow—G. tinctoria in its double form, for instance, and the quaint trailing G. sagittalis. The more dwarf hypericums also supply fine blobs of yellow—notably olympicum, fragile and Coris. Delightful little bushes of pink and rose are furnished by the æthionemas, which should have sun and a light soil. The sea pinks (Armeria) must not be overlooked, with their plump cushions and erect flower-heads of pink running to fine crimson, as in A. maritima Laucheana and A. plantaginea splendens.

This catalogue could be prolonged indefinitely by the addition of other genera and species which, though generally less showy individually than those which have been referred to, equal or exceed them in beauty and interest. But the text which was given to me was *colour* in the rock garden, so I have confined my attention to a few of the more showy things. It remains to point out that mere masses of bright colour are not the only things to be aimed at for permanent satisfaction. The softer tones are needed to rest the eye and to set off the brilliant spots of colour, and proper attention should be given to plants in which the foliage is a leading feature. Thus the achilleas are of first importance, not so much on account of their greyish white flowers as their silver and grey-green, fine-cut leaves. And the dainty mounds of delicate foliage supplied by the various species of corydalis, the grey, green or brown carpets of acæna and cotula, the silver of the artemisias, and the green or blue tones of the dwarf conifers must all be called into service in our scheme for the complete rock garden.

Even among those genera which supply most of the summer colour in the rock garden beauty of form will make a more permanent appeal than mere wealth of bloom. Gaudiness cannot long hold out against grace, and ultimately one's favourites will often lie among the less showy things. Thus Campanula Raddeana with its thin tuft of graceful leaves and deep purple flowers, and C. Tommasiniana with its hundreds of slender bells hidden away among the narrow foliage on its arching stems will outlive C. portenschlagiana in one's affections, and one will cherish Hypericum cuneatum long after one has ceased to thrill over H. olympicum.

HEALTH AMONG THE ROSES

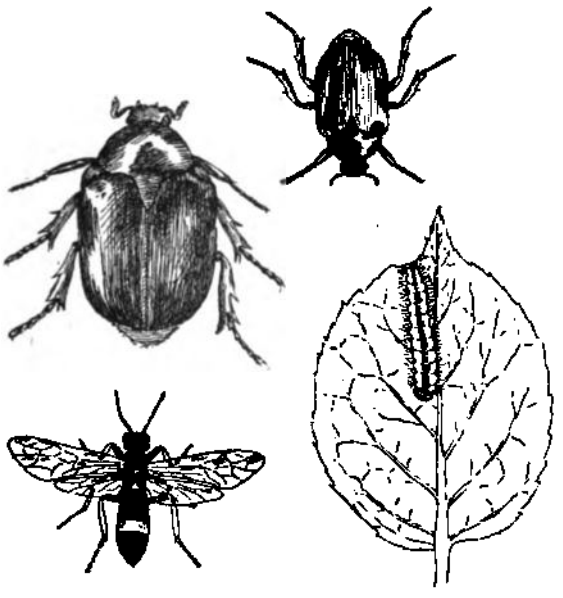
THIS IS THE TIME OF YEAR WHEN ROSES HAVE TO BE WATCHED WITH THE GREATEST CARE FOR SIGNS OF INSECT PEST OR DISEASE. UNFORTUNATELY, THEY SEEM TO BE RELISHED BY PESTS MORE THAN MOST FLOWERS.

SINCE the mission of the rose is to give pleasure, not only should its blossoms excite admiration and, if possible, surprise, but twig, branch and tree should unite in presenting a picture of perfection and beauty; but it is far from easy for even an expert to achieve this, the rose being good food for many insects and several kinds of fungus. Its raiders are many and various and leave behind them nakedness or disfigurement.

To meet such attacks with success, the health of the tree must be maintained, and suckers watched for and thoroughly eliminated. It should have the advantage of a position suited to its variety, sheltered from the more trying winds of its district on ground that has been well drained. It should also be supplied each year with sufficient manure to support its blossoms and water enough to keep it in free growth.

If not doing well after standing long in one place, transplanting and root pruning may separate it from underground foes and renew its health and vigour. While if it seems drastically out of health, buds or cuttings should be taken to renew the stock.

The aphis, from its small size and powers of quick reproduction is a most troublesome pest. As soon as it is noticed the tree should be sprayed with an emulsion of soft soap and water with tobacco or quassia; repeated on the next day, and in a bad case again on that following. A thorough syringing with plain water should follow the use of the emulsion some twenty-four hours later, to cleanse the leaves from the soap. The larvæ of the lady-bird (coccinellidæ), lace wing (chrysopidæ), and hover fly (syrphidæ), live upon aphides, scale, etc., and should be protected.



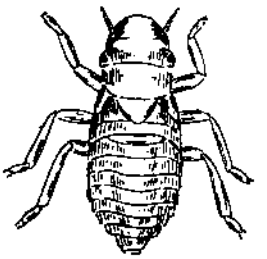
CETONIA AURATA. PHYLLOPERTHA HORTICOLA.
EMPHYTUS CINCTUS. LARVÆ OF SAWFLY.

The leaf hopper appears something like the aphis, but is flatter, has shorter legs and is fish-shaped, with a pointed tail. The larva runs quickly and the pupa can scarcely be distinguished from it without careful comparison, except that it has two "buds" where its wings will develop later. The perfect form has long wings covering and protruding from its body and a sudden and disconcerting habit of hopping. The leaves on which it has fed have a whitish look in the parts from which it has eaten the epidermis and green colouring. It destroys the digestive work of the leaves and should be sprayed with tobacco emulsion or other mild wash under as well as above the leaves.

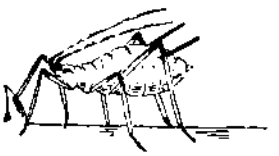
The scale (coccidæ) is not as easy of detection as the aphis, resembling a rounded protrusion of the bark, but its presence is very weakening to its host. When young it is small and active. The female takes a position on the stem, thrusts her haustellum, or beak, through the cuticle and spends the rest of her life in absorbing nourishment, building a scale to cover herself and progeny, and depositing the eggs which hatch under her minute roof. The male coccidæ have wings and no beak. Like the aphis many females of this family are parthenogenetic. If a paraffin and soap emulsion be used against this pest it should be applied before the budding of the leaves. If time can be given, the scale may be rubbed off with a cloth wetted with an emulsion of soap with tobacco or quassia, watch being kept and the treatment repeated at short intervals. Observation in late summer would be necessary lest any scale be left to start a new cycle.

The frog-hopper (cercopidæ) is more easily dealt with, but should on no account be neglected. The froth inside which the larva is usually concealed, being manufactured from the sap of the host plant is an evidence of those deleterious misdoings which cause serious drainage of sap, likely to affect the production of blossoms and general health of the tree. The insect is variable in colour. Of a group of six just found in a piece of froth on a leaf they vary in size round three-sixteenths of an inch, and in colour between pale green and creamy yellow. Two widely separated brown eyes help to give a reason for the name of "frog," emphasised in their perfect form by their habit of hopping. The trees may be treated by syringing with a tobacco emulsion, but this is better preceded by hand picking or at least by strong syringing with plain water, as the froth is adhesive and protects the hopper both from the force of the spraying and its chemical effects.

The larvæ of the sawfly make their attack in different ways according to their species. The leaves may be found rolled with the green larva of Blenocampa pusilla inside and should at once be picked off and crushed. The upper surface of the leaf may be eaten



THE FROG-HOPPER.



ROSE APHIS.

by Eriocampa rosea (light green), or Emphytus cinctus (dark green spotted with white), may eat up the leaf. In any case the tree should be sprayed with hellebore or other suitable wash and the surface soil taken away in the winter and burned.

Chafers are troublesome in two ways; in the first place their larvæ feed upon the roots, and if there should be reason to suspect their presence, the earth round the trees should be dug in winter and thoroughly examined for white grubs, the end of whose bodies are bent beneath them.

Three kinds of chafers, the June bug or cock chafer (Melolontha vulgaris), the garden chafer (Phyllopertha horticola), and the summer chafer (Rhizotrogus solstitialis), beside the beautiful rose beetle or green rose chafer, feed in their perfect stage upon the actual leaves and petals of the rose. The only way of preventing this is to watch for, pick off and destroy the intruders. They are strong fliers so that at no time are the roses safe from them.

A close watch should also be kept for caterpillars, large and small, those from a dozen or so of moths find wholesome food on the rose tree and as some are minute they may elude anything but careful search. The perfect form of one of these, the winter moth, has only rudimentary wings, cannot fly and is scarcely recognisable as a moth.

All folded or rolled leaves should be picked off and dropped into insecticide, as well as those blistered or spotted,

Digitized by Google

indeed, the latter are far better burned without delay.

Thrips, those minute black insects known as "thunder-flies" (Thysanoptera), feed on the coloured layers of leaf and flower and may be cleared by spraying with water or a mild wash.

Red spider is only likely to be troublesome under glass and is best treated by fumigation. If it should be found out of doors, spray with black sulphur at intervals.

Fungus is a most insidious and annoying enemy; it shows itself in several forms the chief of which are given here.

Mildew (Sphærotheca pannosa) is an appearance of mould over-spreading the leaves which is apt to attack immature growth and must not be confused with the whitish patches which result from the attacks of the leaf-hopper. While good washing and watering is helpful, a damp close atmosphere is deleterious. Mr. F. V. Theobald recommends fine spraying with one part of sulphuric acid in one thousand of water after scraping off and burning the fungus or dusting with flowers of sulphur.

Black spot (Actinonema rosea) shows in dark or black patches from the middle of June or earlier, and may cause the affected leaves to fall too early. These leaves should be removed and burned when first seen and both tree and surrounding earth kept free from dead leaves and stems. For this and other fungi black sulphur (sulphate of potassium) may be used on the spring shoots.

Rose rust (Phragmidillim subcorticum), producing orange spots, and leaf scorch (Septoria rosea), causing brown marks, call for prompt treatment. Affected leaves should be removed and burned, and the spring shoots sprayed with an emulsion of sulphate of potassium; or, where the stems are affected, equal parts of methylated spirit and water may be rubbed upon them.

Sooty mould (Fumago), which lives upon honeydew, sometimes follows upon the presence of aphides. Measures should be taken against the latter and the mould will cease to be troublesome.

A practical gardener recommends for insect pests in general a mixture of a wineglassful of paraffin in a gallon and a half of water, the mixture to be repeatedly drawn with a syringe from the bottom of the receptacle and returned to the surface of the blend immediately before use, so that there is no danger of touching the foliage with a drop of crude paraffin.

M. L. BROOKE.

BLUE FLOWERS

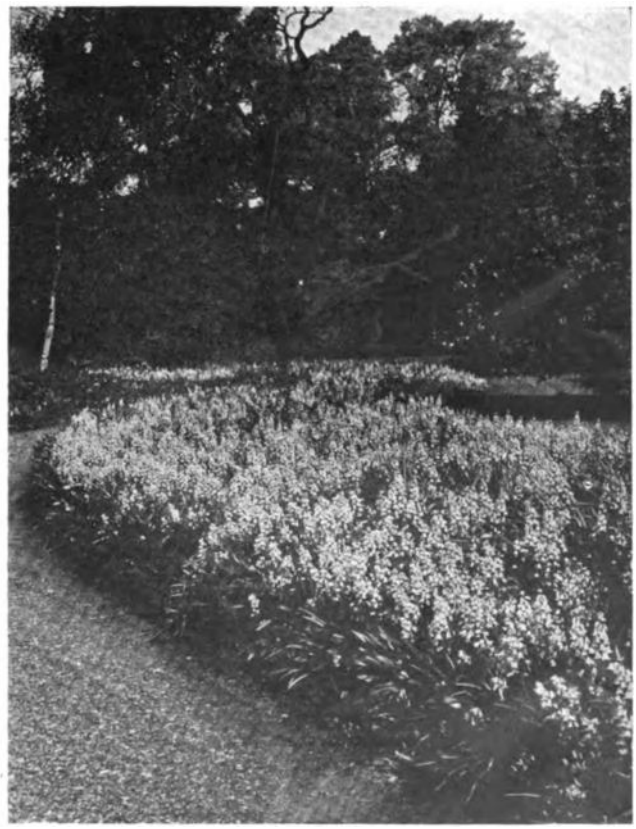
BY SIR HERBERT MAXWELL, BART.

THIS IS A TIMELY ARTICLE POINTING OUT THAT THERE ARE BLUES AND BLUES. MOST PEOPLE REALISE THE NECESSITY OF SEGREGATING MANY PINK AND ROSE SHADES, BUT FOR SOME REASON BLUES HAVE BEEN LEFT TO MIX AS THEY CHOOSE, AND SOMETIMES THEY CLASH.

Greens forsaken and yellows foresworn
But blue is the prettiest colour that's worn.

WHATEVER truth there may be in this old country jingle, it is certainly a fact that blue flowers attract most attention from casual visitors in a garden. There are blues and blues, of course, and it is well that in flowers this colour, which affects the human optic nerve more powerfully than any other, is all but invariably softened by an admixture, however slight, of red, as in echium; of yellow, as in Bailey's variety of Meconopsis simplicifolia, or of both, as in Aconitum Fischeri. Even the blossoms of Salvia patens and Gentiana verna, which approach crude blue more nearly than any other border plant that I can think of, may be truthfully painted with French blue and with cobalt respectively; but both these pigments contain a faint tinge of red.

These remarks came to mind after looking at a thriving plant of the Himalayan hound's-tongue — Cynoglossum nervosum — a species which, though perfectly hardy, is not often met with in private gardens. Of all forms of keepsake or, as the French prettily term it, *porte-bonheur*, there is none that so surely reminds one of an absent friend as does a living plant. Thus, year after year, when this hound's-tongue puts forth liberal racemes of rich blue flowers in late May, I am reminded of the old friend from whom I received it many seasons ago—the late Sir Isaac Bayley Balfour. I think that Mr. John Weathers cannot have been acquainted with this choice species, else in his excellent "Practical Guide to Garden Plants"—a fat volume crammed with useful information—he would not have dismissed the whole genus cynoglossum as "scarcely suitable for the flower garden," while admitting Lindelofia spectabilis, which is far inferior in beauty to the other.



THE SPANISH SQUILL IS NOT SO RICH IN SHADE AS OUR S. FESTALIS.

All colour being relative and our perception thereof purely subjective, the hue of every flower is powerfully affected by that of neighbouring flowers. It is well, therefore, to note in one's pocket-book such chance combinations as enhance the brilliance of blossom, or mar it, with a view to future re-arrangement. Thus last year I removed a batch of Hippeastrum (Habranthus) pratense from proximity of a bush of Buddleia globosa. Though both these plants are natives of Chile, they swore horribly at each other when in simultaneous bloom. Unluckily I replanted the hippeastrum close to a good clump of Pentstemon Scouleri, and now it is flaunting its orange scarlet flames over the rosy-lilac blossoms of the pentstemon. If I am spared to see another summer, hippeastrum and hound's-tongue shall be so stationed as mutually to add to their respective richness of colour.

Equally rich in colour to Cynoglossum nervosum and some ten days later in flowering is a hound's-tongue which we

Digitized by Google

have labelled here C. appeninum, but I cannot find that name in the Kew Hand-list or elsewhere. It is a desirable herb, and if the old flowering stems are cut off, it repeats the display in autumn to compete with the sky-blue blossom of the biennial C. amabile. The latter is indeed a lovely thing, but it has one objectionable quality as a border plant, namely, the profusion of burrs which it produces. These are of a desperately adhesive nature, impossible to extricate from the coat of any dog that comes in contact with them

Another blue-flowering plant has earned my gratitude to Mr. E. A. Bowles, from whom I received it, not on account of the quality of its colour, which is a pale, rather washy tint, but because of its virtue as a carpet for bulbous things. This is Veronica filiformis (not to be confounded with V. filifolia), which spreads with extraordinary rapidity, never rising above 2ins. or 3ins. high, and sheets itself in a mist of grey-blue blossom. Presently a series of roscœa will push through the carpet, beginning with the broad-leaved R. Humeana, followed in succession by R. cautlioides, the purple R. capitata, and the pale sulphur-coloured kind named "August Beauty," which I take to be just a late-flowering variety of R. cautlioides.

The Spanish squill—Scilla hispanica (campanulata)—is not of so rich a blue as our native S. festalis, which in England has appropriated the name of bluebell, assigned in Scotland to the harebell; but the flesh coloured variety of this Spaniard is a charming plant. So is the white-flowered variety, and all three take as kindly to British woodland as our own species. More refined in colour than either of these squills is the graceful Pyrenean Hyacinthus amethystinus, whereof the fairy bells are of a delicate sky blue. The specific name chosen by Linnæus for this plant is singularly inappropriate for there is no suggestion of amethyst purple in the blossom. No doubt he named it with a herbarium specimen before him.

ONE OF THE FINEST OF SKY-BLUE COLOURED FLOWERS, GENTIANA FARRERI.

Of paler blue than Camassia esculenta, but much statelier in habit, C. Cusicki rears its fine spires of blossom in early June. It is far the best of the genus.

The late Mr. Reginald Farrer has added a fresh charm to late summer by discovering and introducing the sky-blue gentian that bears his name. It is as good natured as it is beautiful, easily raised from the seed which, be it noted, is borne at the top of the style instead of the usual position at the base. It thrives abundantly in gritty loam and peat, kept moderately moist, but special vigilance is required to remove seedling grasses which so closely resemble the foliage of the plant as to defy detection until the grass is above the flower.

ANOTHER FINE SKY BLUE, CYNOGLOSSUM AMABILE.

I have referred above to Major Bailey's variety of Meconopsis simplicifolia. Among all hardy flowers known to me it is without a rival in its peculiar shade of blue, at once brilliant and soft, and enhanced by the silky texture of the corolla. One may describe it as Cambridge blue, but there is a suggestion of primrose suffusing part of the petals and a touch of purple at their base, producing an effect verging on prismatic. Then the bright green style, boldly protruding from a dense circle of golden anthers suspended on blue filaments, completes a blossom of extraordinary richness and fully 3ins. across. Unluckily the plant is monocarpic, but produces plenty of good seed which should be carefully harvested.

GARDEN FURNITURE

GARDEN FURNITURE IS ALWAYS NECESSARY FOR THE CAREFUL AND PROPER APPRECIATION OF A GARDEN, ESPECIALLY IF IT IS A LARGE ONE. HERE ARE A FEW IDEAS ON THIS IMPORTANT SUBJECT

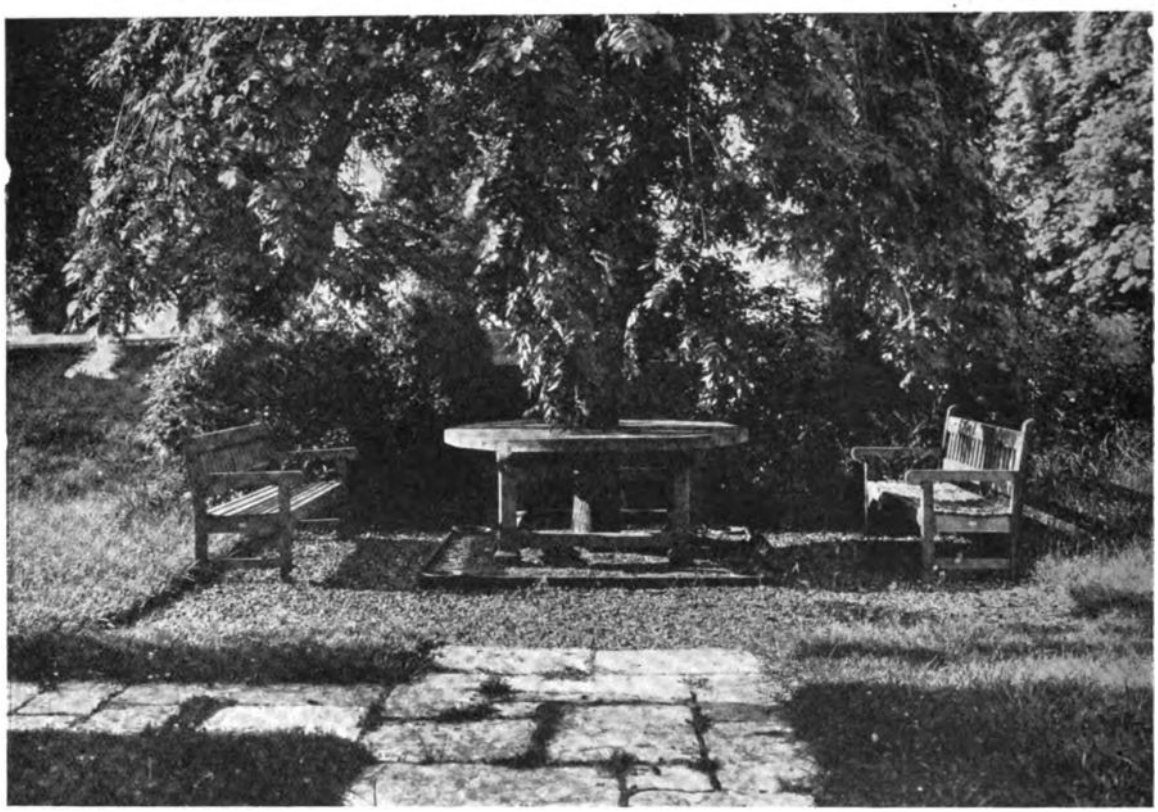
NO garden worthy of the name is complete without suitable furniture. Unless, however, this is of the right kind, it will detract from instead of adding to its charm.

Seats may be constructed in various materials, iron, wood and stone being the most common. The iron seat is generally to be avoided; it serves utility rather than beauty, and rarely, if ever, is it comfortable to sit upon. A combination of wood and iron is little better as regards appearance, but it will not easily succumb to the action of the weather.

Wooden seats are obtainable in great variety from all makers of garden furniture. Simple seats can be fashioned at home or with the help of a local carpenter, but the more elaborate types of circular work require a considerable amount of technical skill, and even those which are of quite simple character need to be put together in a competent manner if they are to be worthy of occupying a prominent position in the garden. Many people who would not countenance a home-made piece of furniture inside the house seem to think that almost anything will do in the garden. This, unquestionably, is a mistaken notion, and money is well expended on the purchase of well designed and well made seats that will not only remain sound for years, but also will be sightly and satisfactory, instead of having the casual and amateurish look of a makeshift.

The most pleasant of wooden seats are those constructed of moderate sized timbers, modelled on good structural lines, and without any effect of ostentation or showiness. The most durable material is either teak or oak, but where cost is a consideration sound deal may be used. A good example of a simple painted wooden seat, supplied by Messrs. John P. White and Sons, is shown in an accompanying illustration. If kept regularly painted and placed so that the legs are out of the damp, deal garden furniture will give a useful life of service. As a precaution against damp it is a good plan to pave the space under and around the seat; stone flags or brick being used for this purpose. This will not only keep the wood away from the damp earth, but will enable the seat to be used with greater comfort after rain. Incidentally, also, it may be noted that paving around the seat has an advantage over grass on a summer evening, inasmuch as one does not then get bitten on the legs by gnats and other insects that come out of their hiding places in the grass in the cool of the evening.

Wooden seats designed on the lines of good furniture are greatly to be preferred to those of the "rustic" variety, which often are the very reverse of comfortable, and all too frequently by their super-rusticity look anything but happy in the garden surroundings with which they are supposed expressly to harmonise.



A COMFORTABLE RESTING PLACE UNDER A CANOPY OF GREEN.

At the end of a grass or other walk a segmental or semi-circular seat, with perhaps a table standing in front of it, always looks well, and gives a point of interest. A circular seat arranged around a tree is also an effective form. Other curved shapes can be obtained in the correct size and form to suit any spot.

In a garden which has some informal or wild portion, opportunities are given for forming many a sylvan resting place. The simple bench type of seat, a board supported by tree stumps, or a seat fashioned out of an old trunk, is admirable in such a setting. Here their rustic character is perfectly in keeping with their surroundings, but such a treatment should not be introduced into a garden where formality of any form has been followed: and now that we have generally abandoned the practice of landscape gardening which was evolved and prosecuted with such vigour a hundred years ago by "Capability" Brown, and perpetuated in a minor way by the meandering paths and polygon beds of Victorian

Digitized by Google

days, it may be taken that the great majority of gardens to-day are of a more or less formal character.

The most durable of all garden seats are those of stone, though admittedly they have not the inviting character of wood, and need some form of covering in the form of cushions or a wood top if they are to be used for sitting upon with comfort and safety. Such seats may be constructed either of rough stone (often to be found in and around the garden, or obtained from a local stonemason's yard or from some friendly builder) or they may be wrought stone benches of architectural character. These latter make very effective features in the garden, expecially when they are set against a background of yew.

For portable chairs, seats and tables in the garden, cane is coming increasingly into favour, and it is noteworthy what admirable models are being produced. We all remember the weird contortions which makers of cane furniture took such delight in. It was ill-natured stuff, and as unsatisfactory in everyday wear as it was unseemly in form. It reached its zenith a decade or so ago, in company with a riot of fatuous bamboo furniture. But these creations belong to the past, and if not forgotten are at least unfollowed. Cane furniture of this kind was a byword both in the house and the garden. Now a very different sort of cane furniture is being made by firms who are using the material in a proper way. Cane chairs, seats and tables for the garden, alike excellent in form and sound in construction, are available in great variety. They are serviceable in use, stand a vast amount of wear and tear, and in general are admirable examples of modern craftsmanship. They are designed on proper lines and show cane as it should be used. Those shown in the illustration are made by the Dryad works. One of the handiest of all chairs for carrying about the garden is the deck chair. So far its disadvantage has been that the canvas seat takes a long time to dry. Now this fault has been obviated in the case of a chair called Collier's Detachable Canvas Deck Chair. In this the canvas can be removed and rolled up in a couple of seconds.

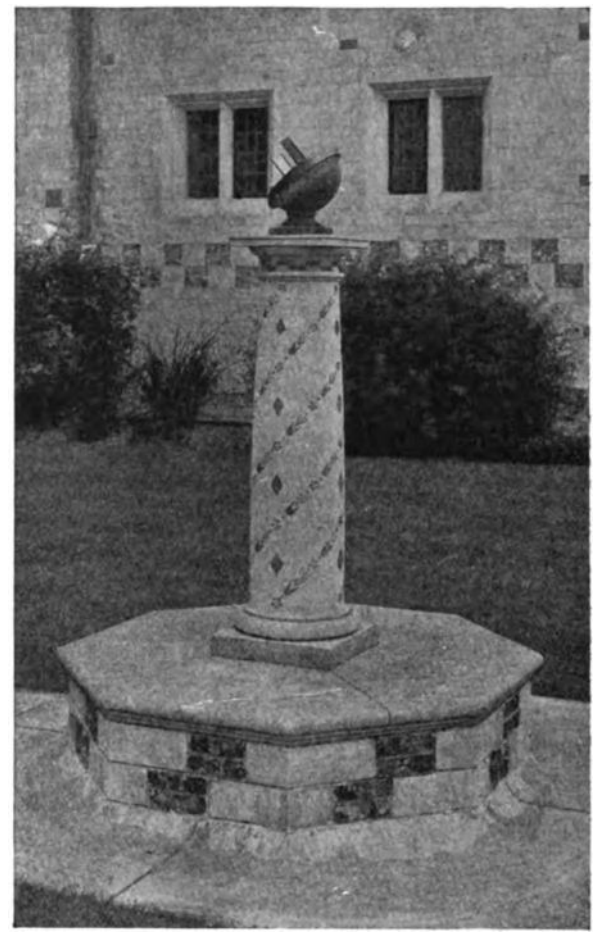
A SIMPLE PAINTED DEAL SEAT.



A MODERN SUNDIAL AT MARSH COURT.

With regard to the most suitable position in which to place seats in the garden, something more than utility and comfort need to be taken into account. Seats should be placed so that, primarily, they give an attractive view of the garden. At any spot commanding a particularly pleasant prospect there should be set a seat to invite its leisurely appreciation. A seat should never be placed on an uninteresting walk or facing some tall hedge or unalluring portion of the house, as there will be nothing in that position to induce one to use the seat. Arbours, loggias, recesses in walls and hedges are essentially the places where seats can be set to best advantage.

With regard to tables, many of the foregoing remarks about construction and design apply equally in their case, and need not therefore be repeated. Tables are apt to get very dirty if left continually in the open. Therefore they should be light, so that they may be readily carried under cover, and also they should lend themselves to being scrubbed when necessary. Wood fulfils these requirements admirably. If of oak or teak, they are best left untouched by varnish, but other wood tables should be painted in some light colour. They should be on quite simple lines and devoid of ornamentation. Sturdiness is a primary necessity, and the legs should be such that the table will stand firmly even on irregular ground.

In the garden, seats and tables are intended essentially for use, and, when choosing them, their everyday requirements and lasting qualities should be kept prominently in mind.

Another section of garden furniture—that consisting of urns, vases, sundials, and so on—is so important that it

Digitized by Google

must be given an article to itself. There is, however, one point which should be mentioned here, and that is that antique sundials and other decorative ornaments have no monopoly of charm of design. Some modern productions show a sense of design which is quite equal to that in the best of the older pieces. A good example of a simple modern sundial is shown in the illustration on the previous page. Indeed, for a modern house and a garden designed on twentieth century lines good modern decoration is often more in keeping than old or classical design.

THE GREAT SUMMER ROSE SHOW

THE National Rose Society held its Summer Show in the grounds of the Royal Botanic Society on Friday, June 27th. The weather was glorious and the attendance very good.

Although the majority of blooms were good, we did not consider the show quite represented the standard of excellence prevailing in rose gardens throughout the country this season. There was only one gold medal new rose, but five were awarded certificates of merit. The new roses impressed us with their high average excellence but there was nothing of sensational interest.

The competition for the big nurserymen's classes for roses in boxes was fairly keen, and the blossoms of perhaps better than average size and form, but there were more stained and battered flowers than we had expected to see. In the class for seventy-two blooms, distinct varieties, Messrs. Frank Cant and Co. were placed first. Their outstanding bloom was an especially fine specimen of Capt. O. Fitzgerald. Other particularly good flowers noted were of Mrs. Hugh Dickson, Bessie Brown, Clarice Goodacre, Mabel Drew and Betty Uprichard. Messrs. B. R. Cant and Sons, Limited, were second with some splendid flowers of such as Mrs. Henry Morse, Betty Hulton and Edgar M. Burnett. Messrs. D. Prior and Son, Limited, were third.

In the class for thirty-two varieties, three blooms of each, Messrs. Frank Cant and Co. were again to the fore. Their trios of Mabel Drew, Mrs. Foley Hobbs, Mrs. Charles Lamplough and Mrs. Andrew Carnegie were among the most noteworthy. Messrs. B. R. Cant and Sons were a good second with fine blooms of Edith Cavell, Nellie Parker and Bessie Brown. In Messrs. D. Prior's third prize exhibit a beautiful trio of Lemon Pillar called forth much admiration.

In the class for forty-eight blooms, distinct, the competition was very keen indeed, but the judges placed Mr. George Prince first, Messrs. English and Son second and Messrs. J. Burrell and Co. third. Mr. Prince had fine flowers of Mrs. Courtney Page, Souv. de Georges Pernet and Mrs. Henry Morse; Messrs. English a really top-notch Red Star and good blooms of Mrs. R. W. McClure and Mrs. J. R. Allen; while Mme. Jules Gravereaux, Mrs. Charles Lamplough and Glory of Steinfurth were noteworthy in Messrs. Burrell's exhibit.

In the class for twenty-four blooms the judges again had an unenviable task. Mr. Elisha J. Hicks was placed first with outstanding flowers of Mabel Morse, and Mrs. Courtney Page; Mr. Sidney Hicks was second with Frau Karl Druschki and Lemon Pillar very fine; and Messrs. Chaplin Brothers, were third with a badly arranged box containing many really fine blooms, of which we noted especially Bessie Chaplin and Lady Alice Stanley.

Mr. John Mattock had the best thirty-six varieties of decorative roses, and he showed Isobel, Golden Emblem, Carine and Mme. Edouard Herriot. In the second prize collection of Messrs. Jeffries and Co. there was a lovely vase of Sheila Wilson.

Isobel, Sunstar, Christine, Golden Emblem and Emma Wright were prominent in the first prize eighteen varieties shown by Mr. George Prince, while Mr. G. Lilley, who was second, included a large vase of the new gold medal rose Marcia Stanhope.

The twelve vases of dwarf polyantha roses were placed in the annexe tent. Mr. George Prince was first with such sorts as Ellen Poulsen and Cecile Brunner.

During past years it has been the rule to find the best tea and noisette roses in the Amateurs' Section, but on the present occasion the Nurserymen's exhibits were distinctly the best. Mr. George Prince won the D'Ombrain Cup with a splendid collection of such delicious varieties as Golden Gate, Mrs. C. Hall, White Maman Cochet, Mrs. Myles Kennedy and Alex. Hill Gray. Mr. Henry Drew was second, and he had lovely blooms of Lady Plymouth, White Maman Cochet and Mrs. Edward Mawley.

Similarly, the classes for new roses distributed since January 1st, 1920 was a distinct improvement on former years. Mr. Elisha J. Hicks won the first prize with a highly meritorious collection. His dozen included Mabel Morse, a glorious rich yellow rose which was shown consistently well in various collections; Captain F. S. Harvey Cant, deep pink; Ed. Behrens, rich crimson; S. de G. Pernet, shell pink; Bessie Chaplin, a very shapely rose which may be described as a larger and more pointed La France; and Mrs. Hy. Bowles, vivid pink. Mabel Morse and Bessie Chaplin were also well shown by Mr. George Prince, who won the second prize with a collection which in former years would easily have been first.

The first prize basket of a new rose of similar introduction to the above was of Mrs. F. J. Hudson, a coarse-petalled pink hybrid tea of large size, shown by Mr. Elisha J. Hicks. Messrs. B. R. Cant and Sons were second.

The baskets of cut exhibition roses generally were very charming, though not so numerous as usual. Charles E. Shea, shown by Mr. G. Prince, was the best basket of any hybrid tea variety. Mrs. Foley Hobbs was the best tea rose and it appeared both in the first and second prize baskets, which were shown by Mr. Mattock and Mr. Drew.

Decorative roses in baskets made a glorious display. Messrs. Chaplin Brothers, who had the best seven baskets, showed Betty Uprichard, Admiration, Mrs. Tresham Gilbey, Lord Charlmont and Joseph Hill. Mr. J. Charfield-Parker was second. Mr. John Mattock was first with three baskets of Golden Emblem, Isobel and Mrs. Henry Drew.

The only exhibit of two baskets of roses not yet in commerce was by Messrs. Chaplin Brothers, who showed Ellen Terry, a shapely creamy white, and Windsor, a rose flushed scarlet which shows a distinct "eye" when fully open.

The groups of roses were again splendid monuments of glorious blooms and they entranced a large number of visitors throughout the day. In the large class the championship was won by Messrs. Alex. Dickson and Sons with a high quality collection. Lady Inchquin, Clara Curtis (an almost Maréchal Niel yellow variety which received a gold medal at Norwich a few years ago), Gorgeous, The Queen Alexandra Rose, Col. Oswald FitzGerald, Maud Cuming, Golden Emblem, Shot Silk and Fred. J. Harrison are the names of a few of the varieties shown in such good quality and quantity. Mr. Elisha J. Hicks, who was second, had several fascinating arches of roses where he associated such sorts as Hoosier Beauty with Romeo, and Golden Opelia with Alex. Girault.

In the smaller, but still large, group class premier honours were won by Messrs. Chaplin Brothers. At each end they had a charming arch of roses; Mrs. Henry Bowles and Golden Emblem with Paul's Scarlet Climber, which were very effective. Their central panels of Mabel Morse, Henrietta and General McArthur provided brilliant colouring. Along the front the parti-coloured Rosa Mundi attracted a deal of attention. Messrs. A. J. and C. Allen won the second prize with a fine collection of such sorts as Independence Day, Betty Uprichard, Golden Emblem, Hortulanus Buddé and Mabel Morse.

The smallest of the three large group classes were equally closely contested and here Messrs. Jarman and Co. won the first prize.

NOTEWORTHY NEW ROSES.

[The following notes on the roses in the New Rose Tent were compiled under very awkward conditions, as the Society did not this year extend its usual facilities to the horticultural Press. It is just possible, therefore, that some variety of merit may have been overlooked.]

Chastity (Climbing H.T.).—A semi-double white of moderate size; pretty in the bud state and apparently a good grower. This variety had already the certificate of merit and Cory Cup to its credit. Shown by Messrs. F. Cant and Co.

Phyllis (Climbing Polyantha).—Said to be the result of crossing Perle D'Or with Gloire de Dijon, this is an attractive pillar rose. The blossoms are rather small, of coppery salmon colouring paling to lemon, edged pink, and almost the "Glory" fragrance. Shown by Messrs. S. Bide and Son.

Royal Scarlet (Hyb. Wich.).—A bright crimson, semi-single pillar rose. Shown by Messrs. Chaplin Brothers.

Hengist (Mult. Rambler).—A really beautiful and apparently strong-growing newcomer to a very useful but rather out of fashion class. The flowers are single, dog-rose pink with a distinct yellow flush. Shown by the Rev. J. H. Pemberton.

Hereward (H.T.).—A semi-single crimson variety with conspicuous buffish stamens. A very pretty rose at its best, but apparently variable. Shown by Dr. P. Arthur Hendley.

Little Juliet (H.T.).—A very free-flowering little rose of Juliet colouring. Shown by Messrs. D. Prior and Son.

Kirsten Poulsen (Poly. Pom.).—A rather cupped single after the style of the now well known Vesuvius, but with crimson blossoms. Shown by Messrs D. Prior and Son.

J. F. Looymans (H.T.).—A fairly full-centred variety of orange buff colouring, sometimes centred pure orange, or, again, paling to lemon on the outer petals. Attractive, though variable. Shown by Messrs. D. Prior and Son, Limited.

Etna (H.T.).—Messrs. Prior and Son again showed this beautiful large semi-single in splendid form. The colour is rich crimson, suffused maroon.

Else Poulsen (Poly. Pom.).—A salmony rose semi-single or semi-double sort. Shown by Messrs. D. Prior and Son.

Digitized by Google

Elvira Aramaya (H.T.).—A moderate-sized bedding rose of almost pillar-box red colouring. The blossoms are fairly full. Shown by Messrs. D. Prior and Son.

Hera (H.T.).—Bluish crimson and maroon, apparently constant to colour; medium to small and globular. Its outstanding attraction is its real and strong old-rose fragrance. Shown by Messrs. D. Prior and Son.

Little Joe (H.T.).—This crimson-scarlet single had already received the certificate of merit, but attracted a good deal of attention. Shown by Messrs. D. Prior and Son.

Insulinde (H.T.).—A pretty small bedding or decorative variety with stout petals and good foliage. The colour is orange-buff, paling to deep ivory. Shown by Messrs. D. Prior and Son.

Ethel Chaplin (H.T.).—A variety that appears to vary from ivory-white to primrose-yellow. The flowers are large, full, bluntly conical, with petals of moderate substance. Tea scent. The foliage is excellent. Certificate of merit. Shown by Messrs. Chaplin Brothers.

Fragrance (H.T.)—This aptly named rose received a certificate of merit in 1923. It is a crimson sort, inclined to blue. Shown by Messrs Chaplin Brothers.

Ellen Terry (H.T.).—This variety is much in the way of Ethel Chaplin, but with more distinct touches of ivory and buff. The flowers tend to be even larger and the foliage is equally as good as that of Ethel Chaplin, but smaller. Tea fragrance. Certificate of merit. Shown by Messrs. Chaplin Brothers.

J. N. Hart (H.T.).—Very large rose pink blooms, moderately fragrant. Good foliage. Shown by Messrs. Chaplin Brothers.

Agnes Glover (H.T.).—A rich bright crimson variety suffused maroon. Slightly fragrant. Shown by Messrs. Chaplin Brothers.

Everest (H.T.).—Very large lemon white sort which should prove useful on the show table. It apparently throws a few rough blooms. Tea scent. Shown by Messrs. W. Easlea and Sons.

Capt. R. Clerk (Pernet).—Almost a pure vermilion semi-single sort with conspicuous golden stamens. Shown by Messrs. S. McGredy and Son.

Doris Trayler (H.T.).—The blooms are almost apricot, paling towards the edges. Shown by Messrs. S. McGredy and Son.

Cecile (Pernet).—A good orange yellow sort with deep golden anthers. Certificate of merit. Shown by Messrs. Ben. R. Cant and Sons.

Vesuvius (H.T.).—A large deep crimson maroon variety. Shown by Messrs. S. McGredy and Son.

Mrs. Beatty (H.T.).—A good butter yellow sort with excellent foliage. Certificate of merit. Shown by Messrs. Ben. R. Cant and Sons.

Mrs. S. W. Burgess (H.T.).—The flowers are orange and buff paling towards the edges. It has a tea fragrance and good leathery foliage. Shown by Mr. S. W. Burgess.

Marcia Stanhope (H.T.).—A good fragrant large white sort, much in the way of Frau Karl Druschki. White roses are scarce and this should prove an acquisition. Gold medal. Shown by Mr. Geo. Lilley.

Peggy England (H.T.).—The blooms are deep cream suffused apricot. It has good foliage and is fragrant. Shown by Mr. Geo. Lilley.

Lucy Constable (H.T.).—A deep salmon red sort, with outer petals of flesh colour. Shown by Mr. Geo. Lilley.

Superb (H.T.).—A silvery rose sort with good large blooms and excellent foliage. Slightly fragrant. Certificate of merit. Shown by Mr. F. Evans.

Joan Howarth (H.T.).—This rose received a certificate of merit last year. It is a silvery rose sort flushed coppery orange. Sweetly scented. Shown by Messrs. Bees.

Hypatia (H.T.).—The blooms are deep apricot salmon with curious golden stamens edged brown. Shown by Messrs. Bees.

Mabel Turner (H.T.).—This variety received a certificate of merit last year. It is a silvery rose with shell-like petals. Of good form, this rose is slightly fragrant. Shown by Mr. Sandy Dickson.

Bertha Turner (H.T.).—A flesh-coloured sort slightly suffused copper. It is more after the style of La France. Shown by the Rev. J. H. Pemberton.

Richard E. West (H.T.).—This rose received a certificate of merit last year The large, loose bluntly conical flowers are pale yellow in colour. Shown by Messrs. Alex. Dickson and Sons.

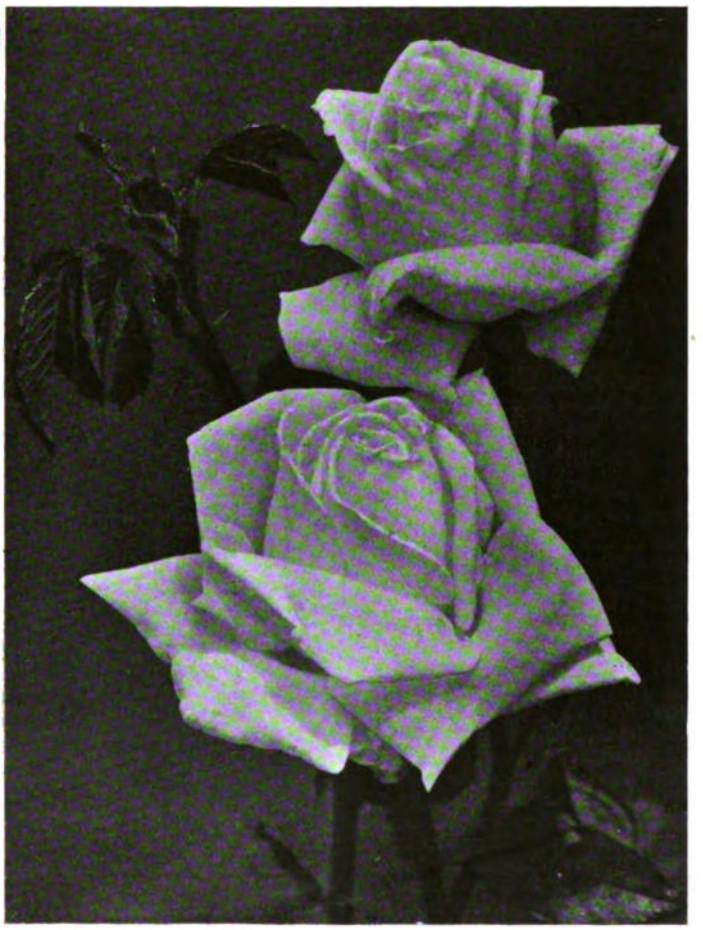
Geo. H. Mackereth (H.T.).—A very good crimson sort. It is sweetly fragrant. Shown by Messrs. Alex. Dickson and Sons.

Gwynne Carr (H.T.).—A good fragrant pale rose-coloured sort with shell petals. Shown by Messrs. Alex. Dickson and Sons.

Saltaire (H.T.).—This rose is a little more than semi-double and has velvety blush crimson flowers and the petals are gauffered. It is moderately fragrant and has golden stamens. Shown by Messrs. Alex. Dickson and Sons.

Lady Wakefield (H.T.).—An apricot-coloured rose suffused old gold. Shown by Messrs. Ben. R. Cant and Sons.

MRS. BEATTY, A GOOD BUTTER YELLOW SORT.



ELLEN TERRY, WITH DISTINCT TOUCHES OF IVORY AND BUFF.

The Amateur and Artistic Classes have unavoidably been left over till our next issue.

NOTES FROM CONTRIBUTORS

LINNÆA BOREALIS.

IN some gardens there seems to be a good deal of difficulty in establishing this plant. We may, it is true, be aided by climatic conditions, but apart from these almost anyone should be able to satisfy this hardy little northerner provided they can afford it a shady, or half-shady, spot such as is enjoyed by native ferns and mosses. The most suitable companion you can give L. borealis is an old tree trunk, if half-decayed and moss-grown so much the better. Partly bury this in any cool, leafy place and just behind it, so that the plant can trail towards the light, set your linnæa in a well drained bed of really old leaf-soil, the blacker the better, and sand, with a few buried stones about the size of a tennis-ball. With this treatment and attention to moisture during the first season this plant should go ahead vigorously, making trailers a yard long. L. borealis canadensis is a much stronger and easier plant than the European. It is larger in all its parts, and the pair of fragrant little bells which swing on dainty upright stems at intervals along the creeping branches are a brighter rose. I have seen this form growing in full sun in British Columbia—such sun as we never get—and looking even happier than the plants which veiled the moss-crowned boulders of the densest pine forests. But they, the former, always had an abundance of moisture, water constantly trickling out of the banks which they adorned with so much elegance and charm.—N. WALES.

RANUNCULUS LIBANOTICUS.

I WAS greatly taken with the vase of this beautiful and uncommon plant which Mr. E. T. England of Exeter staged at the Midland Daffodil Show this year. In the distance it looked for all the world like a bunch of small scarlet poppies rising on thin stems from gracefully divided foliage. I have drawn both Nicholson and Bailey blank, nor can I find it in any of my flower books. Mr. England saw it at the International Exhibition in 1913 and bought some, but he has not seen it or heard of it anywhere else except in his own garden. It is a perennial which increases very freely from seed. It is quite hardy at Exeter and "stands all their frosts without turning a hair." Mr. England says it likes a sunny and well drained position and concludes his letter thus: "If it is to be planted in the North I should advise keeping some of the roots in *moist* earth or sand in the potting shed until growth starts in the spring. Rot before it is established is the only thing to be afraid of. I know I found here that it paid to keep seedlings in pans till spring, but when it seeds itself *in situ* it can take care of itself." It flowers in spring and has "the great merit of filling in the gap between daffs. and tulips." My friend knows nothing of its history. Perhaps some reader who knows this plant will tell us more about it. It more than rivals Anemone fulgens in brilliancy.—JOSEPH JACOB.

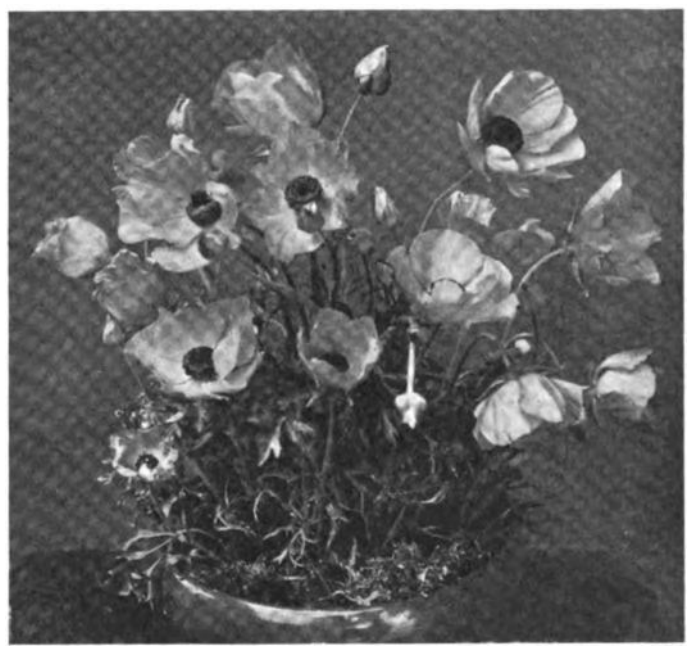
PROPAGATING NARCISSUS TRIANDRUS CALATHINUS.

HAVING frequent enquiries as to the best method of increasing this chaste and charming little daffodil, I will give the method which, after many experiments, we have adopted here, and which seems the most successful. We use large deep pans filled with sifted peat and a slight admixture of sand. The coarse stuff left from the sifting goes into the bottom of the pans. The bulbs are planted in this and the plants are wintered in a cold house, being left in the same pans for two years. From two year pans turned out to-day (June 28th) we find that many single bulblets have become three good flowering bulbs, clean and shapely.—F. HERBERT CHAPMAN, *Rye*.

CATTLEYA MOSSIÆ VAR. MRS. J. T. BUTTERWORTH.

READERS of THE GARDEN might be interested to hear of this remarkable variety of Cattleya Mossiæ, which was exhibited before the Massachusetts Horticultural Society at Boston, Mass., U.S.A., on June 7th, 1924. The writer has been growing orchids off and on for about forty years, and has always been interested in anything new in that line, especially anything of outstanding merit. This variety, Cattleya Mossiæ Mrs. J. T. Butterworth, as regards size and quality of the flower and general vigour of the plants exhibited, as far as the committee of five that examined them knows, stands in a class by itself among Mossiæs. The following is the official description rendered to the Society: "Cattleya Mossiæ Mrs. J. T. Butterworth. A deep pink form of C. Mossiæ, clear colour all through, 9½ins. from tip to tip, lip 3ins. across and deeply fimbriated, light magenta, with deep yellow veinings in the throat." Size of flower (max. 25), 24; cultural perfection (max. 10), 10; rarity (max. 15), 15; floriferousness (max. 10), 8; quality of flower (max. 25), 24; colour (max. 15), 14. Total, 95 points out of a possible 100. Mr. J. T. Butterworth, Framingham, Mass., U.S.A., was the exhibitor, and received a First-class Certificate of Superior Merit and the Mass. Horticultural Society's large gold medal. The committee were unanimous in their decision, several of them having watched with interest this variety for several years. Mr. Butterworth has now forty plants of Cattleya Mossiæ Mrs. J. T. Butterworth, which he has propagated from one plant, each of them showing as much vigour as the parent plant after it was established from the wilds.

The same gentleman also exhibited sixty plants of Miltonia vexillaria in variety, many fine forms being among them. The plants were remarkable for size and vigour, each being covered with flowers of fine size and texture. The leaves were stiff and leathery. This exhibit also received the Society's large gold medal. Mr. Butterworth during the last few years has been pushing into the front rank as an orchid enthusiast and cultivator, and no doubt his English friends will be pleased to hear of his success, as only a month ago he captured two gold medals from the American Orchid Society's great exhibition held in Boston, Mass.—GEORGE F. STEWART, *Waltham, Mass, U.S.A.*



A FINE BOWL OF RANUNCULUS LIBANOTICUS.

ROSE MARY MERRYWEATHER.

AT the Summer Show of the National Rose Society in 1922, the late Mr. Ernest Merryweather invited me to admire his firm's new yellow rose of the above name. That he had a high opinion of its merits its very name sufficiently testified, but I could not find anything about the blossoms exhibited to awaken much enthusiasm. The variety struck me as a paler and probably inferior Lady Hillingdon. Mr. Merryweather insisted, however, that I should give it a trial, and in due course three strong bushes arrived. As grown in the garden the newcomer is as unlike Lady Hillingdon as can be. The growths are strong, spiny and erect; by no means short-jointed it is true, yet the whole plant is altogether "cobbier" than Lady Hillingdon.

Though I quickly realised that "M. M." and Lady Hillingdon were "the Poles apart," I did not in 1923 form a very high opinion of the Southwell introduction. This year, however, I have had from my trees a large number of almost perfect blossoms — of good size, splendid texture, lovely form and delightful colouring. The petals are very stout and shell-like, very large, and so arranged as to form an ideal bud for the buttonhole. At this stage the colour is as rich as that of Lady Hillingdon, but without the buff tone. The expanded blooms have about two rows of petals round a fine cluster of golden stamens and vary according to weather conditions from lemon-white to primrose-yellow. Arranged in a low bowl, they are as beautiful as water lilies. The tree, evidently, is long-lived and very decorative in the garden. Even after allowing for the fact that this is quite an exceptional rose season, it seems evident that Mary Merryweather is a variety that should be largely planted.—R. V. G. W.

FORTHCOMING EVENTS.

CORRESPONDENCE

A CHRONICLE OF EVENTS.

SIR,—It is an Englishman's privilege to grumble, and surely an English gardener is doubly worthy of the privilege. Almost every spring he has more reasons to grumble than to rejoice. It is therefore gratifying to read our Editor's appreciation of the current season (page 428), and I am tempted to add these few lines. We have planted trees and shrubs extensively here during the past three years, and as I look around now (June 22nd) I realise that in this district at least we have enjoyed a really good spring. Rhododendron flowers have been especially fine, both in size and colour, and we were, perhaps, fortunate in that our plants have flowered more freely than appears to have been the case in many parts of the country. Two of the most pleasing were R. campylocarpum × Fortunei, which opens creamy pink, fading to cream, and R. Fortunei × Thomsoni, which has already been commented on in THE GARDEN.

Prunuses have been good, and special mention might be made of Prunus Pissardi Blireiana, a semi-double bright pink flower far in advance of the type. The new Pyrus Eleyi had a few flowers and promises to be the best of the pyrus family. Cotoneasters flowered well and are well set for their autumn display of fruit. Magnolias have been, and still are, good—amabilis, speciosa, Kobus and Soulangiana are past, but parviflora is still very beautiful and Watsoni charms all who go near it with its delicious scent. Philadelphuses in variety, and especially P. virginale—probably the best of the mock oranges—are particularly good. Crinodendron Hookeri in a corner of the house is flowering well, the red flowers being conspicuous against the white walls. Close by Veronica Hulkeana had flower-spikes 2½ft. to 3ft. long. I took a few of the smaller ones to a meeting of our local gardeners' society and made our president—a reverend gentleman of garden label fame—quite envious.

I do not think even the herbaceous plant enthusiast need grumble this season. Lupins and irises have never been so good. Alas! that the iris season should be so soon over. But we bear in our minds till next May and June some beautiful clumps of Iris King, Lord of June (a very fine sort, but rather weak in the stem), Mrs. Cowley, Alcazar, Mrs. Darwin, Gajus, King of the Blues, etc. The delphiniums are 6ft. to 7ft. high, the best spikes being from Phyllis, Blue Boy, Blue Queen, Queen Wilhelmina, Sir Douglas Haig, Mrs. Shirley, Mrs. Thompson, J. S. Brunton and Mrs. Townley Parker. But besides being a good season, the irises and delphiniums are now in their second season from planting, probably the best.

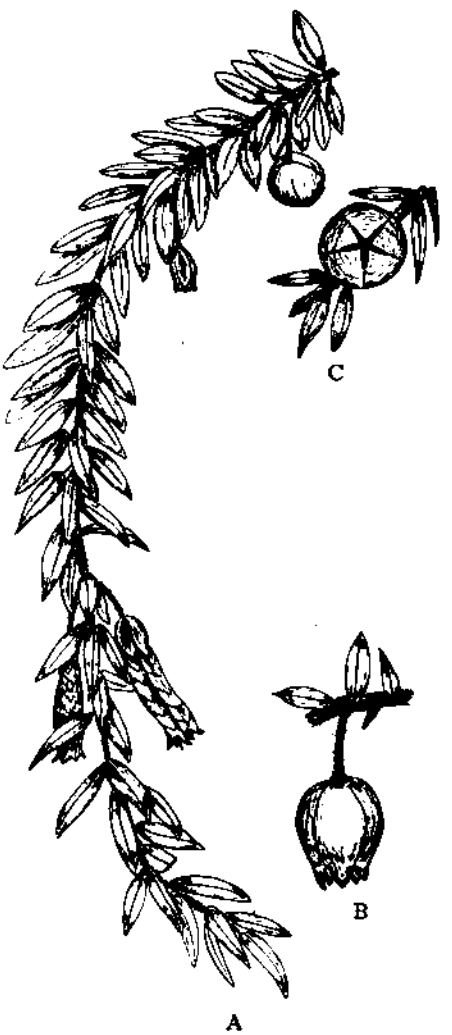
Will the rosarians grumble this season? As I write I can see down two rose borders, and the question comes to my mind, Shall I ever see them better? I doubt it. These borders of roses are for cutting only, and among the best are Ophelia (we place this first), Golden Ophelia, Irish Elegance, Irish Fireflame, Mme. Edouard Herriot (this, I think, is overrated), Mme. Mélanie Soupert, K. of K., Golden Emblem and General McArthur. As a cut rose the latter will never be displaced. One small bowl will scent the whole house.

Of our failures liliums are, I think, the worst, though this is due more to hares, rabbits and slugs than to climatic conditions. LL. regale, sulphurgale, Henryi, elegans, speciosum and Farreri are doing quite well. We have also a very fine clump of L. umbellatum grandiflorum, which at the time of writing is magnificent in the herbaceous border. I have always been grateful to Mr. Wallace that he inadvertently sent us this for L. tigrinum.

During my nineteen years in the Southampton district I think 1923 was our worst season. This, so far, is among our best. "'Tis not in mortals to command success" as the gardener knows only too well. To deserve success takes him a long way towards it. But the deciding factor is without doubt those elements over which he has no control. For the kindness of these elements I am pleased to add my thanks to those of our worthy Editor.—F. J. R., *Southampton.*

PENTAPTERYGIUM SERPENS.

SIR,—This cool greenhouse plant belongs to the Natural Order of Vacciniaceæ. It is a native of the Himalayas and a good flowering plant. Figure can be found in



the *Botanical Magazine*, Vol. CX, 1884, T. 6777, with a description by J. D. Hooker. Up to the present there does not seem to be any record of this plant fruiting in Great Britain, although hand pollination has been resorted to. At the beginning of this year during my study in botany I was put on to the pollination of flowers, Pentapterygium serpens being one of my subjects. The flower which produced the berry was first pollinated on February 2nd of this year, and the pollination repeated several times during the following week. The fruit developed and became ripe at the end of May, and was sketched on June 1st, 1924. The diagram A is three-quarters natural size, while the side view and the surface view, B and C, are about natural size.

It has been stated by J. D. Hooker in his description in the *Botanical Magazine* quoted above that the fruit is a berry ½in., broadly obovoid, five-winged. The fruit obtained in the Royal Botanic Garden, Edinburgh, however, shows no wings whatever, the calyx having swollen until the fruit is practically globular. The berry is white with the calyx teeth and the line of fusion of the sepals tinged with purple. After the fruit had been removed from the plant, in two or three days the purple colour had spread throughout the whole of the fruit. The berry is also larger than is indicated by J. D. Hooker, being five-twelfths of an inch in diameter by half an inch.—A. MARGARET MITCHELL.

THE PROPAGATION OF CHOISYA TERNATA.

SIR,—As the innocent originator of the extensive correspondence on this subject, I feel I cannot allow the remarks of Mr. A. T. Johnson in THE GARDEN of June 28th to pass without comment. In the first place, if my original article of May 3rd were to be read carefully, it would be seen that the point which I wished to raise was: "How long can cuttings of this plant keep green in a pot without roots, and if at the end of two years (as in my case) there was any chance of the formation of roots?" The question in my mind was whether to throw them away or not. I should like to thank Mr. F. P. Knight for his most helpful hints on the subject in THE GARDEN of May 17th. Since writing my article one of the cuttings has rooted and is growing freely. I cannot conceive why Mr. A. T. Johnson should consider this a controversy or that I have "gone out of my way to do things in the most difficult manner conceivable." Also, as his article is headed "The Propagation of Choisya ternata," why should he spend more than half of it describing how he propagates Romneya Coulteri?—(Dr.) H. STEWART WACHER.

AT THE CHELSEA FLOWER SHOW.

When to the Show my Julia goes
I know full well that she will cry
"Oh, what a simply *perfect* rose!
And this, and that, we ought to buy."—
Till, though I try my heart to harden,
I order pounds' worth for the garden.

LESLIE M. OYLER.

GARDEN LABELS.

SIR,—I am grateful to Mr. Holms (page 439) for his championship of the numbered labels I advocate for small alpines in private gardens, but I am afraid I cannot reciprocate when he urges their use for large shrubs. With such subjects the labels are comparatively small and inconspicuous, and the advantages of lettered labels in my opinion predominate. But even here the diseratum of inconspicuousness can be sought by using labels which are not too large or overloaded with lettering. An alphabetical book of reference will still be necessary to contain interesting and instructive details such as those which Mr. Holms collects as to his rhododendrons. May I add that I cannot tacitly accept the suggestion contained in Mr. Holms' humorous comparison of my humble self with the promoter of the Daylight Saving Bill. I do not claim to be the inventor of numbered labels for alpines. I expect many people have discovered for themselves their advantages, and I can only hope that the ventilation of the system in THE GARDEN may induce others to try it.—EDWARD S. LYTTEL.

SIMPLE GARDENING

LAYERING STRAWBERRIES.

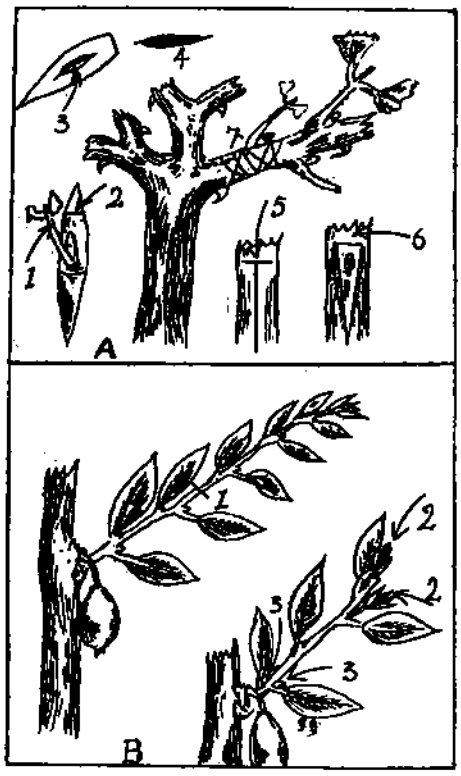
BEFORE all the fruits are gathered, it is necessary for the cultivator to make a start with the work of providing young stock for new plantations. These early-rooted runners are very valuable, and great care should be taken of every suitable specimen. I mention suitable runners because there are always unsuitable ones, and it means just as much work and expense to grow the latter as the former. The best runners are those growing from the plants that are bearing, or have borne, this year, a full crop of fruit. Also, note should be taken of the nearest plantlet on the runner to the parent plant; there may be two or even three on a single runner, but all beyond the first should be cut off. Do not wait until the runners have begun to root into the soil, but prepare the pots and compost, or the pieces of turves, in good time, and so secure all the new roots in them without a check being given. The best compost is one of fibrous loam two-thirds, and rotted manure or well sweetened horse manure one-third. Especially is this compost advisable in cases where the runners are to be re-potted for forcing. If pots (3in.) are not available, use pieces of old turves 3ins. square or so, and in every instance keep the runner firmly in position with a flat-shaped stone, as the latter conserves the moisture and hastens the growth of new roots.

SOME TROUBLESOME INSECT PESTS.

There are few weeks out of the fifty-two when the various crops in our gardens are entirely free from injurious pests, and one can rarely talk with one's neighbours and friends without learning how much worried they are about the pests. The leaf-mining maggot does a lot of harm; there are several kinds, but we will not deal separately with them here, since the same treatment will prove efficacious almost in every case. We want to learn of a few accessory means of prevention and cure. The respective flies that lay the eggs in the leaves dislike ammonia, and this can be applied by using soot in liquid or solid form; in liquid, well diluted and clear, syringed on the foliage in the evening; in solid, by sprinkling very small quantities, weekly, of old dry soot on damp foliage and on the soil around the plants. Any small white grubs found in the leaves should be crushed between finger and thumb. Green and black aphides are troublesome on roses, chrysanthemums, etc.; first apply tobacco powder, and one hour after syringe with clear water. The black aphides are got rid of best by dipping the affected shoots in tobacco water. Scald woodlice or trap them with bran or meal under dry pieces of board. Scald ants or trap them by placing two empty flower-pots one on the top of the other; they will make their nests in the top pot. Search for earwigs at night and also trap them in hollow stalks and dry moss in pots.

BUDDING ROSES.

This operation requires delicacy in handling and quickness in despatch. That is, from the taking of the bud from its stem to its insertion in the stock to



be budded, only a few seconds should elapse. It will not do to leave the bud exposed to the air for several minutes. Shoots brought from a distance the previous day should be placed in water in a cool cellar meantime. The operation is simple and quickly done when once the amateur grasps the main details, and all cultivators are proud to be able to bud their own roses.

To bud a standard rose, the best of the lateral growths should receive the buds. One bud is shown, prepared and fixed, in Fig. A; a portion of the leaf-stalk (No. 1) is left when cleanly cutting the bud from a fairly ripened shoot. The top (No. 2) is cut off; No. 3 shows the base of the new bud when the bit of hard wood (No. 4) is picked out; No. 5 s[illegible]ow to make the T cut through the bark; No. 6, the new bud inserted; No. 7, the best position, low down, on the lateral shoot of the standard briar. Use a very sharp knife, open out the bark with the ivory handle or piece of smooth-pointed oak, not the steel blade, dip each bud in water before inserting, secure with soft material.

SUMMER PRUNING OF FRUIT TREES.

In many gardens hardy fruit trees make a great deal of young growth every year and so summer pruning is resorted to. This does not obviate the necessity for winter pruning, but it lessens the amount of work then and, more important still, it conduces to the ripening of the basal buds from which our future crops of fruit come. The whole of a tree should not be pruned in one day; the work should be done gradually, spreading it over a week or ten days. In Fig. B a current year's growth should be cut off at No. 1, leaving four or five main leaves and buds. New laterals will grow as shown at Nos. 2, 2; these should be pinched out while small. The basal buds, Nos. 3, 3, should remain dormant till next year, but they would not do so if the branch were summer-pruned closer to them. This closer pruning must be left till late autumn.

POTTING CANTERBURY BELLS FOR LATE SPRING FLOWERING.

If very fine Canterbury bells are to be successfully flowered in the greenhouse or conservatory from March to May, the young plants should be grown, during their seedling and early plant stages, in an open border; from this position they should be very carefully lifted and potted into quite small pots but just large enough to contain the roots and a small quantity of compost. The latter should be of a substantial character, such as good fibrous loam with a very small quantity of leaf-soil added. The newly potted plants should be forthwith placed in a cold frame or on a bed of ashes on the north side of a wall. In a position of this kind the plants should remain till the pots are well filled with roots, then a re-potting into 6in. pots should be made, the plants being placed on a bed of ashes in a quite open quarter. A similar compost, but in a coarser condition, will be suitable. The plants will bear really good spikes of blossoms in 6in. pots, but by far the finest specimens are those finally potted into 8in. pots. Of course, these are hardy plants and would be spoiled if treated as tender greenhouse subjects. It is only necessary to keep them from full exposure to frosts and fog.

GEORGE GARNER.

Digitized by Google

VEGETABLES DURING THE MONTH OF JULY

TO obtain early vegetables is an aim worthy of encouragement. All sorts of methods are tried by the energetic gardener to overcome difficulties, and each one has usually to deviate from rules laid down by writers on horticultural subjects, and plant and sow by his own dates and methods, which he has proved by experience best suited to the soil and locality in which he resides. Climatic conditions and locality must always be taken into account when timing vegetables, since favourable situations and seasons do make a difference. Then, again, one must not expect to have early vegetables if the proper varieties are not grown, as varieties classed under the heading "early" differ in that degree, and so one has to keep on trying until one finds the kinds which do best for that particular time and place.

KIDNEY BEANS.—To have a crop in July, seed should be sown during April and the plants grown under glass, at least till all danger from frosts has gone, as from two to three months should be allowed from the time the seed is sown until the pods are ready for picking. There is no doubt that Canadian Wonder is a splendid variety and does well either grown in the open or in pots. One year we prepared—on May 10th—several 8in. pots by crocking and filling them with good potting soil; a space of about 2ins. was left in each pot, so that a top-dressing could be applied later. Several seeds were inserted in each pot on the same date. Five or six plants are quite sufficient to grow in an 8in. pot, but it is always wise to insert rather more than that number of seeds. The pots were set in the tomato house, where a fairly warm temperature was maintained. Under these conditions the young stems were not long in pushing through the soil; then by frequent syringings and attention to watering the plants grew apace, and a month later they were supplied with stakes. On June 21st the plants were in flower, while at the end of the month we supplied them with extra nourishment. This we did by filling the space which was left in each pot at the time of seed sowing, with farmyard manure. A week later the first pulling of beans was obtained, and throughout July the plants kept us supplied with fine beans, many measuring over 6ins. in length. The plants were never removed from the tomato house, but once they were established they received abundance of air during fine weather.

CABBAGES are always appreciated, especially when the hearts are young and tender. To make certain of a supply in July, seed should be sown about the end of July or August of the previous year, as, in a year like the present, cabbages —even those classed as early varieties— have taken a very long time to mature, and throughout the present month we shall keep cutting from Flower of Spring and Little Pixie, which were raised from seed sown on July 24th and the young plants set out in September of last year. I may state, however, that our cabbages suffered much from the cold cutting winds which prevailed throughout the latter half of February. The variety Ellam's Early Dwarf—which is a quick maturing and splendid sort—if sown in a cold frame at the beginning of March and the plants set out early in May, will come in for cutting in July.

CARROTS.—Those who do not have a suitable border on which to grow early carrots need not hesitate to sow in cold frames—if these are available—so that pullings may be had throughout the month. Scarlet Model we have sown on April 16th, and the roots were ready in the middle of July. Geurande, which is a stump-rooted variety, if sown in the third week of March will be ready early in the present month. This year we had seed of Early Scarlet Horn sown on a south border by the middle of March, and the roots will come in splendidly for this month's supply. St. Valery, which is given as a French intermediate sort, was sown three days later, on the same border, and the roots are just as far advanced as Early Scarlet Horn. The cleanest and best shaped roots are obtained when holes are made with a dibber and filled with sea sand, and a pinch of seed dropped in each hole and covered with a little sand or fine soil.

CAULIFLOWERS.—One year we planted Early Snowball on April 1st—the plants were raised from autumn-sown seed and wintered in cold frames—and small heads were ready for cutting before June was out, while plants of Early London, which received throughout the same treatment—both kinds being grown side by side—were twenty days later in supplying heads for cutting. So far as varieties go, none can surpass Early Snowball for earliness in our Scottish climate, although Early London is a splendid sort and most dependable for cutting in July. Another method by which Early Snowball can be grown to supply heads for cutting early in the present month is to sow seed under glass in the early part of the year, and prick the seedlings into boxes about the end of February; these should be kept in a moderate temperature till well established, then placed in a cold frame and gradually hardened off. Afterwards set them out in the open ground at the end of April.

LETTUCES may easily be had in July from sowings made in autumn, or seed may be sown under glass in spring and the seedlings set out on well prepared ground when sufficiently grown and fit to handle. The cos varieties take longer to mature. We had the seed of Balloon Giant, a cos variety, sown on the open ground before the middle of September last year. The young plants were set out between the lines of early potatoes about the middle of March; they have grown well. This variety in a small state, throughout the winter, was very dark in colour, but several weeks after being moved the leaves became green, no doubt owing to the better weather with longer days of increased light. In the past we have sown New York cabbage lettuces early in June, and had them for use in a small state throughout the latter part of July. Tom Thumb is another fine cabbage variety.

PARSLEY.—When a good breadth is sown about the middle of March, a plentiful supply of fine tender leaves can be had now. Myatt's Garnishing is very good at present.

POTATOES.—It is said that potatoes should be three months in the ground before they are dug up for use. I should say extend this period by at least a fortnight, at any rate in the case of early varieties. Someone might say, What about Victory?—ready in two months from time of planting. That may have been the case somewhere, but I do not think so in Scotland, and certainly not in my experience. There is no doubt Epicure keeps its place as an early and reliable potato, and although scheduled as non-immune, I have never in my experience found it affected with disease. The tubers are roundish in shape with deep eyes. When tubers are exposed to the light for some time, in preparation for seed purposes, their skins turn very dark in colour—one would almost say black. We always save our own "seed" of this variety, and although the prevailing idea is that varieties deteriorate, and one is better with a change of seed, we have no cause to change our custom in connection with Epicure. Other good varieties of potatoes in use this month are Dargill, Sharpe's Express and Witch Hill.

RADISHES.—Both the turnip and long-rooted varieties will be ready for using in four or five weeks from date of seed sowing. Spinach sown early in May comes in for use now, while early varieties of turnips take from two to three months from seed sowing till ready for use. Early White Milan, seed of which was sown just after the middle of March, is ready now. Early Snowball, sown at the same time, comes in a week or two later.

Midlothian. DAVID ARMSTRONG.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Mushrooms.—At this season beds can be made in the open, choosing, if possible, a shady position. Having collected the manure it should be turned over at intervals to allow the rank steam to escape, but it should be made up into a bed while there is enough heat left in the manure to start the spawn. Make the manure firm, and insert pieces of spawn 3ins. deep and a few inches apart.

Shallots.—When the weather is favourable and the bulbs have completed their growth, they should be lifted and placed thinly in an open shed to ripen.

THE HARDY FRUIT GARDEN.

Wall Trees.—Some attention should be paid to pears and plums growing at the base of walls. Strong foreright shoots should be shortened to three or four leaves, or cut away, while other growths may be tied in wherever there is space, and room can be found for extension. Wall trees often become more or less dry at the roots, but this season we have had an ample rainfall, which rendered the use of the hose pipe unnecessary, the growth in consequence being both free and clean. However, a short period of dry weather will soon make a difference, and trees producing a crop should have their roots kept moist.

FRUITS UNDER GLASS.

Vines.—The grapes in the early vinery will either be ripe or just removed, and in either case the house should be ventilated freely. Where the rods are infested with mealy bug, the present is a good time to cleanse them. A little methylated spirit applied with a camel hair brush will destroy this pest, and every opportunity should be taken to examine the rods. Keep the roots well supplied with water, and an occasional application say once each week of liquid manure will assist the basal buds and the vines generally. Later vines should have their lateral growths pinched and the bunches should be examined for stoneless berries, at the same time removing a few berries where there is any likelihood of over crowding. A night temperature of 60° to 65° should be maintained, and under normal conditions no fire heat will be needed, but Muscats will require a temperature of 70°, and often a little artificial warmth is necessary. The borders should be kept moist, and air admitted before there is a big rise in the temperature. When the ripening stage approaches, an inch or so of top ventilation will be advisable throughout the night.

THE FLOWER GARDEN.

Border Carnations.—During the next few weeks the layering of border carnations should be taken in hand, a young healthy stock thus being kept up. It is a simple operation. Select healthy growths, and pull off a few of the lower leaves, a slight longitudinal incision or tongue is made with a sharp knife, and the shoot then pegged down, and just covered with sandy soil.

Tulips.—Bulbs that were lifted to make way for summer bedding plants have dried off, and now should be stored in boxes in a dry shed. All the soil and old loose scales should be removed, and the bulbs kept from mice. T. W. BRISCOE

(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

General Work.—The wet weather during May and the early half of June favoured weeds with ideal conditions for their growth. It is advisable that the hoe should be used every day among the various vegetable crops; not only will the stirring of the soil keep weeds in check, but the fine soil created on the surface will keep the earth below from losing its moisture too rapidly should a spell of dry hot weather set in.

Peas.—Sowings made in the first or second week of last month should be sufficiently advanced now to have the stakes or trainers placed along each side of the lines. Continue to thin turnip crops as seedlings from successional sowings advance in growth.

THE FLOWER GARDEN.

Polyanthuses.—Seedlings from an early sowing should be pricked off into boxes filled with medium fine soil, 2ins. or 3ins. apart according to size. Seed of Centranthus ruber, Hesperis matronalis and H. m. alba may yet be sown on the open border if flowering plants are required for next year.

General Work.—Bedding plants are now thoroughly established, although antirrhinums made little progress for several weeks after being set out, owing probably to so much wet weather. The principal work in this department is now of a routine nature, such as staking and training, pulling or cutting off spent blooms, clipping verges and mowing grass, raking walks and keeping down weeds, so that everything is kept trim and tidy.

Shrubs which produce their flowers from wood made the previous year—such as philadelphuses, some of the spiræas, Veronica Traversii, weigela, etc.—should be pruned so soon as they finish flowering, but only if they are in any way overgrown or are monopolising too much space.

FRUITS UNDER GLASS.

Peaches and Nectarines.—The growths on trees in late houses will require to be tied in and here and there the leaves should be pushed aside, or if very thick a few may be pinched out, if they are in any way shading the fruits, which should be well exposed to light and sunshine. DAVID ARMSTRONG

(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Campanula Vidalii is a very distinct plant, native of the Azores, and is very useful for the conservatory or cool greenhouse. It is easily raised from seed, which may be sown at this time. C. Vidalii takes two years to attain flowering size and is really at its best the third year from seed. This plant will stand outdoors during the summer, and at stages of its cultivation only requires cool greenhouse treatment.

Helichrysum humile.—This pretty South African plant has "everlasting" flowers, and was at one time very popular. However, it is not often seen at the present day, but is well worth the attention of lovers of choice plants. This plant and its several varieties may be propagated by means of cuttings any time during the summer. The cuttings should be carefully prepared, taking care not to tear the bark, and inserted in small, well drained pots, using a compost of sandy peat. Stand the pots under a bell-glass in a cool greenhouse, and wipe the glasses dry every morning.

Kalanchoe flammea, K. Dyeri and **K. kewensis** are all worth growing for greenhouse decoration. They are easily propagated at this time by means of cuttings, which can usually be obtained from the base of the plants after they have finished flowering. Being of a succulent character they should not be stood in close cases, as they root readily if the cutting pots are stood on a bench or shelf in a cool greenhouse. Good examples of K. flammea can be flowered in 48-sized pots. KK. Dyeri and kewensis, being larger-growing plants, require larger pots to do them justice. Well grown plants attain a height of 3ft. when they are useful for standing in the conservatory beds. They all grow readily in any good potting compost, and during the winter are best in a warm, dry, airy greenhouse. J. COUTTS.

THE GARDEN

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2748 Saturday, July 19th, 1924 Price THREEPENCE

The Kelway Colour Border

is planned for continuity of bloom as well as colour effect. Your garden is of enduring beauty from early Spring to late Autumn, and so continues for several years, as a result of the minimum of cultivation, expense and attention.

These Colour Borders have evolved from many years of experience, and clients get the advantage of securing, amongst other subjects, the world-renowned Kelway Specialties in Hardy Plants.

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

We are only too pleased to advise.

WRITE NOW to the inventors of Colour Borders:

KELWAY & SON,

OF FINEST STRAINS AND TESTED GROWTH.

For the Flower Garden.

Antirrhinums, Aquilegias, Campanulas, Delphiniums, Forget-me-nots, Gaillardias, Geums, Hollyhocks, Lupins, Pansies, Papavers, Polyanthus-Primroses, Sweet Williams, Stocks, Violas etc.

For the Vegetable Garden.

Beet, Cabbage, Carrots, Cress, Mustard, Onions, Peas, Parsley, Turnips, Radish, etc.

For the Rock Garden.

Special List of dwarf-growing Hardy Perennials, Alpines, etc., for July sowing in the Rock Garden.

All Lists free on application.

BARR & SONS, 11, 12 & 13, KING STREET, COVENT GARDEN, LONDON, W.C.2.

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know ? this Booklet ?

If you know it, there is no question at all about it: you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

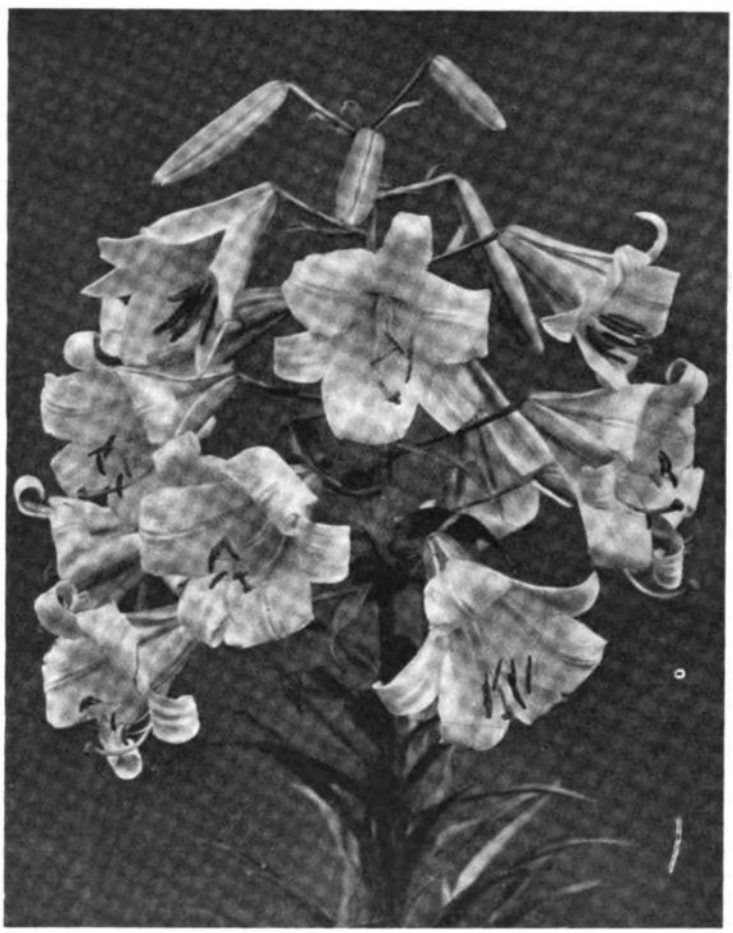
THE GARDEN

VOL. LXXXVIII.—No. 2748. JULY 19, 1924.

We would ask our readers to remember that the "Garden" is produced for the benefit of all gardeners. We are always pleased to consider articles or notes on any horticultural subject. We are also here to answer questions. Below will be found details of our Service Bureau which has been instituted to help gardeners in everything appertaining to gardening.



The wonderful lily, introduced by Reginald Farrer, Lilium centifolium. The flowers, on 7-ft. stems, are white flushed on the inside with yellow, while each petal is shaded on the exterior with deep crimson brown. It appears to thrive equally in any soil, and has a particular liking for chalk, in which it thrives to perfection. As this illustration shows it is a profuse flowerer.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers. The only Service which is not free is the examination and designing of a garden. This will be undertaken by one of our experts at a moderate fee.

Also, there is the further convenience, which the Service Department affords, of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

THE LATE SIR HARRY VEITCH

IT is with regret that I must chronicle the death of Sir Harry Veitch and with pride that I try to enumerate a few of the accomplishments of a career which was entirely devoted to the improvement of gardening in the British Isles. Few have been so lucky as to have seen such a great transition from the burlesque form of gardening carried on in the middle of the last century and to have known that this transition was largely owing to their own steadfast pursuit of an ideal which was in advance of their time, but which has proved itself to be the correct ideal.

I must refer those who wish for family history to notices in other papers, for what I am principally interested in is the actual work accomplished by James Veitch and Sons under the direction of the late Sir Harry Veitch, for Sir Harry Veitch for more than thirty years was the firm of James Veitch and Sons, and their fame up to the time of their giving up business was world-wide.

Probably the first speciality of the firm to gain them renown was the hybridisation of orchids. This had been started while the firm was still at Exeter, but gained its greatest fame under Sir Harry Veitch's management shortly after he took over control on his father's and brother's deaths about 1871. It was during that period that the three Johns, John Dominy, John Seden and John Heal, made their magnificent orchid hybrids for the firm. For many years the hybridisation of orchids was considered a trade secret, but in 1884 Sir Harry Veitch decided that it was his duty to share the firm's secret with others, and so he read his famous paper on "Orchid Hybridisation" before the Fellows of the Royal Horticultural Society.

This was probably the service which brought the firm greatest renown up to the beginning of the present century, but now it is realised that the introduction of numerous new plants brought them infinitely greater credit before gardeners in general. It was through the perseverance of the firm that a great line of botanical collectors introduced such a multitude of plants which are now everyday names in our gardens. These collectors began with William and Thomas Lobb from 1840–60 and ended with E. H. Wilson, who collected for them between 1899 and 1905. It also included such names as Richard Pearce, John Gould Veitch, Carl Kramer and Charles Maries.

I feel that I must give a short list of some of the famous trees and plants introduced through this firm, and this list does not include orchids, greenhouse plants or ferns: Abies concolor, A. grandis, Araucaria imbricata, Cryptomeria japonica, Cupressus pisifera, Pinus Armandi, P. Coulteri, Sequoia gigantea, Thuya dolobrata, T. gigantea, Abutilon vitifolium, Acer griseum, Actinidia chinensis, Davidia involucrata, Deutzia discolor, Dipelta floribunda, Fremontia californica, Hamamelis mollis, Lonicera tragophylla, Magnolia salicifolia, M. stellata, Populus lasiocarpa, Arundinaria nitida, Berberidopsis corallina, Berberis Darwinii, Clematis Armandi, Desfontainea spinosa, Enkianthus campanulatus, Eucryphia pinnatifolia, Hypericum Hookerianum, Jasminum primulinum, Magnolia Delavayi, Olearia Haastii, O. macrodonta, Quercus acuta, Rhododendron auriculatum, R. occidentale, R. racemosum, Viburnum rhytidophyllum, Primula pulverulenta, Thalictrum dipterocarpum, Lilium auratum and L. giganteum. It was owing to this firm that the whole of the magnificent race of tuberous-rooted begonias was evolved, by their introduction from the Andes; and the same with hippeastrums by their use in hybridisation of H. Leopoldii. In addition, under Sir Harry's auspices, a great deal of work was done in connection with the improvement of fruit and vegetables.

This list is longer than I intended, and it could be prolonged indefinitely, but it is a fitting memorial to the late Sir Harry Veitch and to the firm of James Veitch and Sons, for rather than sell the goodwill he dissolved the firm on resigning the chairmanship in 1913–14. In addition to his horticultural work he was most generous towards philanthropic objects and was exceedingly kind to his numerous friends, gardening and otherwise.

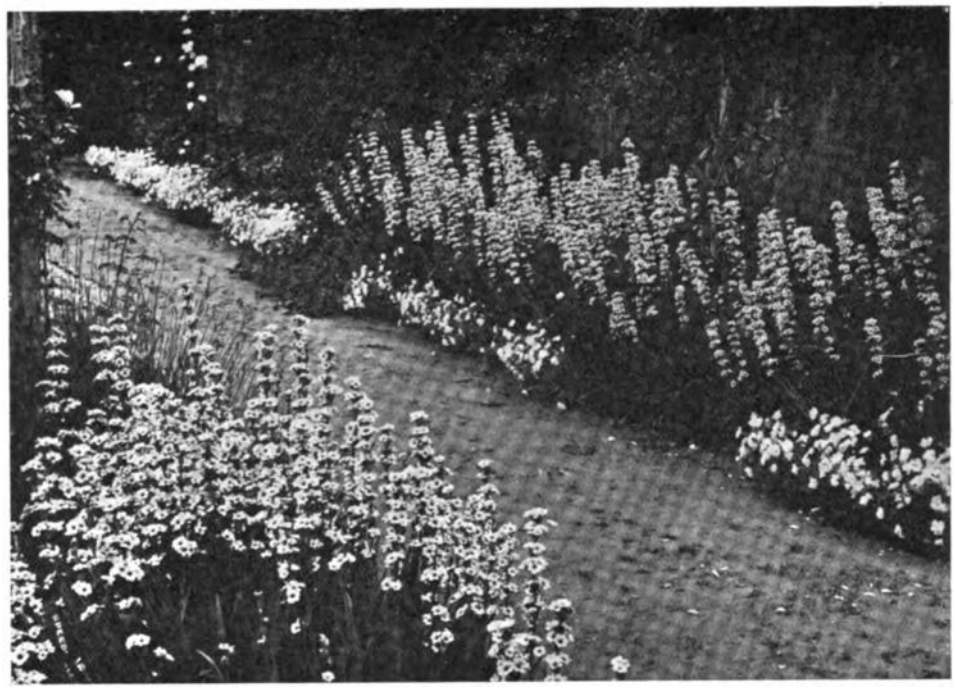
SUMMER BORDERS

BY GERTRUDE JEKYLL.

IT is a great advantage, wherever the conditions of a garden permit such an arrangement, to have special borders for the various seasons; for each one then allows of a display of some definite and complete picture of flower beauty. The border is well filled, and for some fortnight or three weeks the plants show the very best they can do. Such a border may be arranged for the second half of May and the earlier part of June. It has a main planting of the grand old double peonies of the officinalis class, with their bold, clear-cut foliage and massive heads of bloom. They are in three kinds of colour, full, deep crimson, a lighter rosy tint, and a pale pink which changes to a rather impure white. At the back of the peonies, and here and there intergrouped with them, are bushes of Olearia Gunnii and Deutzia gracilis, with the large white columbine, and, again, behind these, white Portugal broom kept to a moderate height by being cut back after flowering. The whole of this white-bloomed company has a further setting of the old herb Sweet Cicely (Myrrhis odorata) with its large fern-like foliage and showy umbelliferous bloom. Also behind the peonies and among the plants of the fern-like myrrhis are tall spires of the pure white foxglove; these also rise from yard-high masses of the common male fern, now in its freshest young frondage. Backing the whole is a double row of cobnuts. The old double peonies have a goodly space some eighteen paces long, and where they end, the peony influence is continued by a length of 4yds. of the single white Backhouse's The Bride, a garden variety of P. Whitleyi, which blooms in succession to the old officinalis. Here at the back is a long drift of the tall early white Iris florentina, and in front of the white peonies another of the shorter, deep-coloured Purple King, with an interplanting of the useful purple-leaved sage. This leads to some groups of blue flowers, a good form of Centaurea montana and a front planting of the true Pulmonaria azurea. Some of the earlier Helianthemums, in white and rosy colourings, are along the front edge.



THE BEAUTIFUL FREE-FLOWERING SISYRINCHIUM STRIATUM.

This border is followed in time of blooming by what we know as the June garden, a double border in quite another part of the garden, backed by edges of flowering shrubs in which guelder rose predominates. Here the main plants are irises and lupins, which are both in perfection in the second week of June. The right-hand border begins with a dwarf yellow iris in front and the tall pale yellow I. flavescens at the back. Then comes a group of white lupin and a generous front planting of Geranium ibericum with its masses of bright purple bloom; after this come pink China roses, harmonising charmingly with the deep red valerian (centranthus); then a bush of Olearia Gunnii, smothered in its small starry white bloom. This is followed by a group of the best form of perennial lupin, with tall spikes of flower in two shades of purple, and handsome foliage of a lighter green than that of the ordinary kinds. With this is the useful white ir- Mrs. H. Darwin and

CHRYSANTHEMUM FRUTESCENS IN THE FOREGROUND WITH CLEMATIS FLAMMULA AT THE BACK

Digitized by Google

ASTERS AND ACONITUM JAPONICUM.

purple columbine and the fine white Oriental poppy Perry's White. These are followed by irises of mixed colouring; good kinds of what were formerly known as squalens, with varying tints of yellowish smoky or misty lilac standards and rich red purple falls. These have a groundwork of the purple-leaved sage and of the dark reddish satin-leaf (Heuchera Richardsoni), both useful plants for quiet harmonious settings to flowers of rich warm colouring. So the border goes on. The opposite side, which more directly faces the sun, gives rather more prominence to yellow colouring, for near the middle of its length is a bush of the gold-leaved privet with a bold group of one of the hybrid mulleins with rich orange and yellow flowers. Here also are large bushes of the half woody hybrid lupins, masses of strong yellow bloom. With them is a large group of the deep yellow Iris aurea, and a shorter iris, deep yellow and claret-coloured. Then again white and purple, leading to the pale rosy Iris Queen of the May and more China roses and Olearia and pink lupins. At the far end is a tall feathery mass of Spiræa Aruncus, and near it the interesting spikes of Asphodelus ramosus, all front-edged with purple cranesbills and catmint (Nepeta Mussini). The aim in these borders is to give a distinct picture of harmonious colouring every few yards, with the groups of plants composing it large enough to avoid any feeling of spottiness; and so to have the colours pass from one to another that the whole retains a pictorial quality.

The early weeks of July bring the clouds of purest blue of delphiniums and of the pale blue variety of anchusa called Opal. These are pleasantly accompanied in the late summer border by the good perennial mullein, Verbascum Chaixii, with the free-flowering Sisyrinchium striatum in front and a still lowlier bordering of the almost prostrate Œnothera missouriensis with its large, pale yellow bloom. Besides its use in the border, the sisyrinchium is a capital plant for any sunny banks in light soil, with, near it, bushes of Phlomis fruticosa, in early July smothered in its curious and showy yellow bloom, all the better shown up because it is neighboured by the handsome blue-leaved grass, Elymus arenarius. Such a combination on a sunny bank in sandy soil, with front plantings of helianthemums and a backing of the hardier cistuses, may be confidently recommended.

Now is the time of roses, and though the newer roses are lovely things, the old garden kinds should not be forgotten; the cabbage rose (Rosa centifolia) of incomparable sweetness, and its variety the moss rose; the damask roses, with the pretty striped and splashed Cottage Maid; the varieties of R. alba, which include the double white rose of cottage gardens; the pink form Maiden's Blush, and the still lovelier Celeste. Although there is now so great a number of the modern rambling and pillar roses, some of the old Ayrshires are still unbeaten—Dundee Rambler and the Garland, Ruga and Bennett's Seedling, besides the still older arbour rose Flora. With the coming of these roses the preparation for making pot-pourri is in full swing.

The subject of one of the illustrations is part of a border for early September, mainly for the display of the early Michaelmas daisies.

THE VICTORIA REGIA

ONE of the most interesting plants in Kew Gardens, the "Giant Water Lily," Victoria regia, is now in its public home; but as yet it shows none of its glory, being but a small plant. Soon, however, its wonderful foliage and flowers will command the admiration of all who see it. It is a native of Guiana, where it covers large areas of the rivers and lagoons, some collectors reporting it in patches a mile square. Its introduction to this country was full of difficulties and it was tried many times without success.

Seeds were received in 1846, and two of them germinated at Kew, but neither matured. In 1849 more seeds were sent, in water, and the resultant plants grew and flowered in 1850. The leaves were so large that they overlapped the edge of their tank and in 1852 a new house was specially constructed for the plant.

FIG. 1.—THE ADULT PLANT.

Digitized by Google

FIG. 2. FIG. 3.

The lily is really a perennial, but at Kew it was found best to save seeds every year and treat it as an annual. When mature the leaves are wonderful structures, often over 6ft. across, with a vertical rim of about 6ins. The underside is covered by a network of strong, spiny ribs, thus forming air pockets which support the leaf. The strength of these leaves varies with the credulity of the listener, but they can certainly support a tremendous weight if it is evenly distributed.

There is a popular belief that the lily flowers once and then dies; but, actually, it flowers very frequently during the summer, each flower lasting two or three days. The flowers are white, changing to pink, having a strong scent and are about a foot across. At the end of its life the flower sinks, and matures its seeds below water. One would not connect the second illustration with such a tremendous plant, but it shows V. regia when a week old. The leaves are about 3ins. long, and the seed, which is about the size of a pea, can be seen.

The third illustration (plant aged three weeks), shows the first stage toward the circular leaf, the next few leaves are perfectly circular, but the rim does not appear until the plant is much more advanced. When it is fully developed, as in the first illustration, it is, without doubt, one of the most striking features of Kew. L. Buss.

COTTAGE AND RAILWAY STATION GARDENS

THE debt we owe to the cottage garden for its contribution to the beauty of the countryside seems scarcely to be sufficiently recognised. The gardens of the well-to-do, surrounded by hedge and fence, may please the eyes of the favoured few, while in these days of restless travel, when country roads are thick with chars-á-bancs, motors and the homely bicycle, the cottage garden lying by the highway is seen by the thousand passers-by.

When driving through country roads we all know the difference between the villages where interest in flowers is kept alive by local shows or the laudable rivalry between natural lovers of the garden and, on the other hand, the villages where the gardens are strictly utilitarian and labour is only given to the vegetable. In the former, spring brings the wallflower, white arabis and polyanthus, and summer the rose, hollyhock, white pink, pansy, London pride and a host of other flowers which, though they may be called "common," hold their own in beauty and scent in any company.

The stately Madonna lily and the old rose Gloire de Dijon seem particularly to revel in the cottage garden and to treat the poor more kindly than their more wealthy neighbours. There are few sights more beautiful than a well established Gloire de Dijon on a cottage wall in full bloom pushing up to the eaves of the thatched roof and clustering round the windows. Clematis montana and wistaria, too, often cover a cottage wall and make a lovely show for the eyes of the wayfarer.

The strictly utilitarian garden presents a very different picture. Nettles straggle through the untidy hedges, tufts of grass and weed fill the little space between road and threshold, and the choked plants and creepers, should any exist, only add to the general air of slovenly neglect. Passing through a village where conditions such as these exist, it is a relief to leave it behind and get into the open country again, for the human habitation seems to leave a stain on the landscape.

We may surely look on cottage gardeners who show their pride and love of their gardens as public benefactors, and if public service be one of the greater virtues, they deserve all the honour and encouragement we can give them. Might it not be possible to give a more tangible proof of our admiration than by taking off our hats to them, and, though we like to exercise our national privilege to the full in grumbling over the present heavy burden of taxation and high rates, those who love the countryside would not grudge a penny in the pound

AN OLD FASHIONED COTTAGE GARDEN.

Digitized by Google

in addition were it to be applied to the beautifying of our villages. Such an entry in the accounts as "Paid to Messrs. Rose and Bush, nurserymen, for plants supplied to villagers at ——" surely would not be severely criticised even in these difficult days.

We pay as cheerfully as we can for such necessaries as policemen and drains for the peace and health of the country, why should not a small outlay be allowed for the decoration of the village and the outskirts of the town? However, this suggestion is made with great diffidence, as in every community there are always those who care not for these things and are as content to look on a corrugated iron roof or a bed of nettles as to gaze on the loveliest beauties of flower and plants. Again, those who have greenhouses and frames could give substantial help by placing their surplus seedlings and plants at the disposal of those who have not these luxuries.

Even those who know nothing of gardening and have little love for flowers must be affected by the colour and scent that greet them as they pass through a village where the gardens are tended with care and are evidently a delight to their owners. When we consider that all the work that is put by the labourer (or his wife) into the garden is overtime, that the first care must of necessity be the vegetable portion, and that the rest is given as a labour of love and pride in the appearance of his surroundings, he most surely deserves all the help we can give him.

The stationmaster is another of our public benefactors who so often refreshes us on our journeys, though I have never heard of him being publicly thanked. How many of our country station gardens are a real boon to the weary traveller, and what a difference it makes to the dull platform when it is edged with borders of flower and shrub. We can all of us recall to our mental vision stations where roses, rhododendrons, wistarias and borders of annuals have cheered us on our weary way.

I do not know whether railway companies make any grant to assist station gardens. If so, as a railway shareholder I applaud the outlay; but should it not be so, I should like, being a frequent traveller, to offer my grateful thanks to the gardener stationmaster for having so often lightened a dull journey.

In these days of educational progress surely beauty is a factor that cannot be ignored, and those who—like the cottage gardener and the stationmaster—add their quota of beauty to the countryside and thereby add to the gaiety and pleasure of the everyday life of the public, deserve our gratitude and thanks.

Though there is, no doubt, a certain virtuous pride of display, entirely honourable, attached to their labours, it is surely not too much to say that the results of their efforts is as much for the pleasure of the public as it is for their own. That the public do enjoy these results there can be no doubt, but, like many other blessings, they are too often taken as a matter of course. M. J. M. VICARS-MILES.

ROSES IN OLD RECEIPT BOOKS

THE coming of summer and the rose harvest meant to those notable housewives, our grandmothers with several greats, a vast increase of their work in the still-room. Turn to any book of receipts, printed or MS., and, you will find directions by the score—sometimes vague, but invariably picturesque—for fragrant, medicinal, or toothsome compounds of which rose petals form the pleasant basis. Predominating among the receipts are those for that rose-water which Sir Hugh Plat, in his "Jewel-house of Art and Nature," advises should be made when "there is a glut of roses in the Market whereby they are sold for 7d. or 8d. a bushel." Rose-water not only played an important part in confections, perfumes, complexion-washes and many other things, but was used by itself as a "cure" for dim sight, fevers and heart trouble. It was also considered "good against the venom of toads and green frogs." That prince of book makers, old Gervase Markham, gives in his "English Housewife," published in 1660, instructions for making a very rare and pleasant Dammask-water "by distilling four hand fulls of Dammask-roses and as many of Red," with the tender leaves of walnut trees (quantity not stated), spices and orange peel in "a quart of Malmsey and a pottle of Spring-water." In rose-water such as this, gloves and leather for jerkins were steeped until thoroughly scented; while if the water were boiled softly on the coals with a little sugar, it would render the whole house fragrant. This was known as King Edward's or the French Queen's perfume.

Perfume cakes for burning, and balls for use as pomanders were made of rose petals pounded in a mortar with civet, musk, ambergris and benzoin worked into a paste with rose-water, formed into any shape desired and dried in a slow oven, the pomander balls being pierced with a skewer while still soft to enable them to be strung. In the receipt for pomander paste given by Dr. Salmon in his "Family Dictionary," 1696, the list of ingredients includes gum-dragon; while Lord Ruthven in his "Ladies' Cabinet Open'd," of 1655—a year prolific in cookery and receipt books—tells his readers that marjoram and lavender should be pounded with the roses.

Some of the receipts for rose confectionery sound so dainty and tempting that modern sweet-makers might try them with advantage, even though the days of roses at 7d. a bushel are no more! Here is a simple one taken from "The Queen's Delight" (1655):

"Boyle your sugar to sugar again, then put in your Red Roses finely beaten and moistened with the juice of a Lemmon. Let it not boyle after the Roses are in, but pour it upon a Pye-plate and cut it into what form you please." And there is a receipt in Rabisha's "Whole Body of Cookery" (1661) which is fascinating reading:

"To Candie Rose-leaves as natural as if they grew on Trees. Take of your fairest roses, red or damask, and on a Sunshine day sprinkle them with rose-water and lay them one by one on a fair paper. Then take some double-refined sugar and put it in a fine lawn searce. When you have laid abroad all your roses in the hottest of the sun, searce sugar over them. Then turn the leaves and searce sugar on the other side and turn them often in the sun, sometimes sprinkling rose-water and sometimes sugar on them until they be enough and come to your liking and this being done you may keep them."

"Take red Rose-buds, clip all the white, bruised and withered from them. To every pound of roses take three pounds of sugar; stamp the Roses by themselves very small, putting a little Rose-water or juice of Lemmons to them as they wax dry. When you see them small enough put the[illegible] to them and beat them toge[illegible]e well mingled. Then put [illegible]alley-pots or glasses."

Among the many other preparations of roses given in Lord Ruthven's little book is included a "Syrup," made by boiling and re-boiling the flowers "in fair water," skimming carefully the while and adding sugar and lemon-juice at the final boiling. This syrup, we are told, "purgeth choler and melancholy."

The making of oil of roses, "Soveraign for any scalding with water or oyle and good for all manner of unkind heats," was a tedious process. The roses had to be infused in "sallet oyl" in an earthenware pot luted with paste which was put in a water bath and set among hot embers for a night. The oil was then strained off, fresh chopped rose petals added and the closely covered jar set out in the sun every day for three weeks. Chiefly medicinal, also, were the uses of rose vinegar, the result of steeping red roses in white wine vinegar for forty days, but it was sometimes introduced as a flavouring into sauces.

To many people, I fancy, it will come as a surprise to hear that pot-pourri is a comparatively modern introduction. Rose petals dried—to quote Dr. Salmon—"on a sunshiny day and turned as you would hay," were used to fill "sweet-pots" as well as "sweet-bags," the equivalent of the scent sachets of to-day, but the elaborate mixture of scented flowers and leaves, spices, aromatic gums and salt, more or less familiar to us, does not seem to have been evolved until the end of the eighteenth century. A pot-pourri receipt in rhyme by Miss Anna Seward is printed in "The Universal Magazine," for April, 1798. It is a lengthy "poem" in the Swan of Lichfield's best—or worst!—style. She sings of "fraxinella's spicy sighs," of "Indian spices' antiseptic glow," of "pale syringa," of "Hispania's lemons," of the mineral "which once was flying Lot's too envious wife," and very many other things, all of which were to be blended until—

"In one vase eternal Summer dwells."

R. E. HEAD.

PEAS AND THE COOKING THEREOF

THE French have a proverb which says "Eat green peas with the rich and cherries with the poor"; which is only another way of saying that peas, to be properly served, want a lot of care and good butter and other ingredients, and must be young, selected and of the best; while cherries can be plucked and eaten off the tree. In fact, to eat peas in perfection they must be gathered the same day and shelled not more than half an hour before cooking. Peas bought ready shelled (to save trouble!) have lost all their flavour and become coarse and hard. They should be also quite young and the smaller sizes should be separated from the larger by sifting through a "riddle" or an ordinary colander. Otherwise, if all the little ones are cooked with the large ones they will be a mash before the big ones are done. A peck of young peas, if the pods are full, may be enough for three persons or even for four if the portions served are small.

Peas in the English Way.—The usual way of serving peas in this country, is as a vegetable with the roast joint. After sifting the smaller peas (which should be added at half-time,) throw a peck of peas into a gallon of *boiling* water with a tablespoonful of salt, and when half done, that is, in about a quarter of an hour, add a lump of sugar and the small peas. Strain, and toss a bit of butter in them just before serving

Peas in the Italian Way.—Take two small onions cut in two, toss them in a little oil (or fresh butter) with a small handful of chopped ham. Then add the peas with a little pepper and salt, and finish cooking them slowly, adding by degrees a little stock and a walnut of butter or a little oil. They should not be too moist. Remove the onion before serving.

Peas in the Indian Way.—Put the peas into a jar with about 2 oz. of butter, some pepper, salt and a lump of sugar and a bunch of mint. Cover the jar very tightly and place in a saucepan of boiling water. Boil till the peas are tender. Peas cooked in this way retain the full flavour better than when boiled in water.

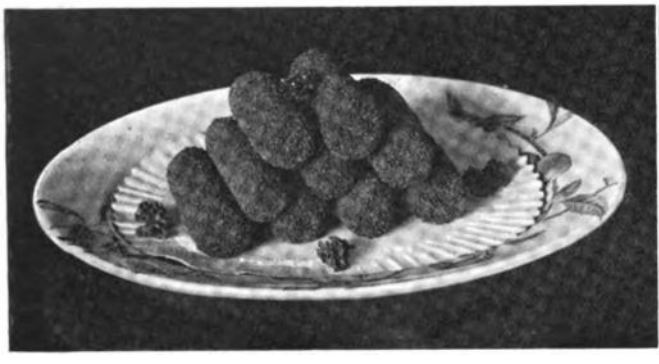
Stewed Peas and Lettuce.—Take a quart of green peas, two good-sized round lettuces cut into small pieces, and a quart of stock. Stew all together in a casserole till tender. Then add a walnut of butter rolled in flour, a spoonful of essence of ham (or two tablespoonfuls of finely chopped ham), and a little pepper and salt. When smooth and thick serve up very hot.

Green Peas with New Potatoes.—Boil some water in a casserole and put in a quart of young peas, and a dozen or more small potatoes well washed but with the skins on, a little salt and a bunch of parsley. Arrange so that the peas and potatoes become done at the same time; then, when both are sufficiently tender, drain them, peel the potatoes, mix all on a dish and pour over a good quantity of hot butter just before serving.

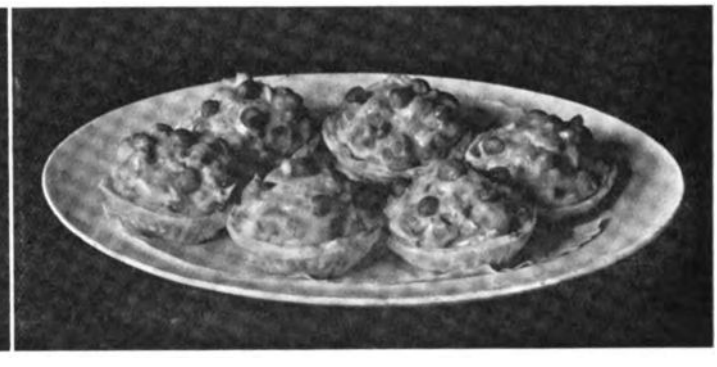
Green Pea Salad.—Chop up together a small onion or shallot, a sprig of chervil and one of tarragon, a little parsley and a very small bit of burnet if procurable. Mix with enough cold peas to make a sufficient dish and pour over the whole a dressing made in the proportion of two tablespoonfuls of oil to one dessertspoonful of vinegar and one teaspoonful of Chili vinegar. The dressing should be added some time before it is required and the salad finally turned over again just before serving.

Green Pea Soup.—A peck of peas should make a large tureen of soup. When shelling the peas put on one side the young and small ones to be boiled separately. Boil the other peas in plenty of water till they are tender, which should take about thirty minutes, and then strain them into a clean stewpan with about five pints of good stock not too highly flavoured. Cover this very tightly and stew over a slow fire for an hour at least. Then add a teacupful of very fine breadcrumbs, mix well, and pass the whole through a hair sieve into a clean stewpan. Stir well, and if too thick, add a little more hot broth. Season with pepper and salt and two lumps of sugar. Before serving put in the small peas which have been boiled separately. Some slices of cucumber, drained and fried a light brown in butter are sometimes served in green pea soup, and are a distinct improvement.

Petits Pois à la Crême.—Simmer (not boil) the shucks of the peas for an hour with a dessertspoonful of sugar, a teaspoonful of salt and two sprigs of mint. Then boil your peas in this liquor over a sharp fire till tender. Strain off the peas when done and make a fairly thick sauce with the liquor and a little butter and flour. Replace the peas in this and warm thoroughly, stirring all the time. Finish with a large spoonful of thick cream and garnish the dish with fried *croutons* cut in fancy shapes. The sauce should be of a fairly thick consistency and the whole served very hot, if possible over a spirit lamp or hot water dish.



GREEN PEA CROQUETTES.



GREEN PEA CASSOLETTES.

Green Pea Cassolettes.—Line some small, but rather deep, round patty pans with thin pastry and bake in a moderately quick oven for fifteen minutes. Toss freshly shelled peas in butter, add some finely chopped ham and sufficient Bechamel sauce to bind, a little chopped parsley, a little nutmeg and a tablespoonful of cream. Fill the cases and reheat in the oven; then garnish with a few peas already cooked.

Green Pea Croquettes.—Cook half a pint of peas, drain and rub them through a sieve. Make a binding sauce with butter, flour and milk and add the sieved peas, mint and seasoning to taste and let the mixture get cold and firm. After shaping, coat with egg and breadcrumbs and fry to a golden brown in a pan of hot fat.

Notes.—Green peas should always have a slightly sweet taste; in fact, sugar should decidedly predominate over salt. The shucks or shells of young green peas can be stewed in plenty of water, and the liquor thus produced makes a good foundation for a *maigre* soup of any kind. Mint is generally boiled with the peas, but some people do not like the flavour of it.

THE USE OF AVENUES

BY PROFESSOR AUGUSTINE HENRY.

AVENUES, as the derivation of the word indicates, were in the Middle Ages approaches to great houses and important buildings, but later came to mean roads, drives and walks that are bordered by trees. These were little known in England till the seventeenth century, when they became a conspicuous feature in the formal style of landscape gardening which was then introduced from France. The first avenues were doubtless formed by cutting long vistas through the forests which surrounded the châteaux of the nobility, and good examples of these may be seen even in England, as witness the long glades running through masses of wood at Savernake. Usually, however, an avenue consists of parallel lines of trees in the open park leading from the great house to the main entrance. There is no reason, however, why such lines of trees should be limited to the approaches to mansions. Throughout the country there are many bare and uninteresting roads which might be made effective parts of the landscape if their edges were planted with trees.

In no country are there so many avenues of varied character to be seen as in England, and the Long Walk at Windsor, composed of English elms, has been described as one of the finest and most imposing avenues in the world. It is, however, surpassed in beauty by some of our beech avenues, of which Finch's Avenue, Watford, is a good example near London. It is formed of straight, closely planted trees, attaining 120ft. in height and closing in overhead. The grand avenue of beech at Savernake is still more wonderful, owing to its great length, the trees forming a continuous green aisle for five miles. Lime avenues are similar in character, as the branches readily meet above, but their trunks are not so beautiful as those of beech. One of the finest lime avenues in England is at Burghley Park, Stamford. The lime avenue at the back of Trinity College, Cambridge, was celebrated by Tennyson; but it is much surpassed by the avenues of lime at Longleat, which were planted in 1690.

As the great effect of an avenue lies in its stateliness, only those species of trees which are capable of attaining a great height should be used wherever the soil and situation allow of their perfect growth. Splendid avenues can be formed not only of the broad-leaved trees just mentioned,

Photograph by permission of the Arnold Arboretum

A FINE AVENUE OF MAGNOLIA SOULANGIANA IN ROCHESTER, NEW YORK.

elm, beech and lime, but also of Spanish chestnut, horse chestnut, London plane, sycamore, holm oak and Lombardy poplar. In the warmer parts of Britain where the soil is free from lime and the situation not exposed to the prevailing wind, the Spanish chestnut grows fast and makes magnificent avenues, as at Flitwick, where the trees planted in 1833 have attained an immense height. There are good Spanish chestnut avenues also at Cowdray Park, Thoresby, and Newhouse Park, near Mamhead in Devon. The lines of horse chestnut in Bushey Park are well known; some of the trees attain 100ft. in height. The sycamore grows well in Scotland and the north of England, and is there suitable for avenues close to the sea and in other exposed sites. The most beautiful tree for shelter in the maritime belt is the evergreen or holm oak, slow in growth. It makes a fine avenue tree at the Norfolk coast. The London plane is mainly

Digitized by Google

used for planting in towns, but it might be employed with considerable effect as an avenue tree in southern England, where it attains an immense size. The Lombardy poplar is very formal and useless for shade, but it can be planted to advantage along roads, where the land on either side is under the plough, and farmers dread the ill-effect on wheat and other crops caused by the shade and wide-spreading roots of ordinary large trees.

Avenues of conifers are as a rule formal in their effect, and should scarcely be planted where the broad-leaved trees just mentioned do well. Conifers, however, are useful on the poorer soils and in hilly and exposed situations. In the maritime belt all round the coasts of England, Wales and Ireland the Monterey pine (Pinus insignis) grows on the poorest soil, provided it is not too wet, and attains an enormous size in forty or fifty years. This species is suitable for avenues, as the trees at that age grow close together and have become pleasingly irregular in outline. The Scots pine when old is one of the most beautiful trees on account of its brilliantly coloured bark and picturesque crown of foliage, and it attains a large size in deep sandy soil. It also thrives in frosty situations. The Corsican pine grows faster than the native species, and is suitable for forming avenues on soil containing lime or chalk. It bears wind extremely well. One of the wondrous sights of the world is the famous avenue of Cryptomeria with closely set enormous boles, which for twenty miles lines like a wall both sides of the road leading to Nikko in Japan. We may have perhaps in 100 or 150 years a similar effect with the Wellingtonia (Sequoia gigantea). There is a magnificent avenue of this species at Wellington College about 1,200yds. long, the average height of the trees being 80ft. at forty years from date of planting. On exposed and wet sites and at considerable elevations, avenues may be formed of Sitka spruce, which has already reached in Scotland and Ireland 120ft. in height at seventy years old. The common European spruce preserves for many years its unpleasing conical form, but improves in appearance when old. Two narrow avenues of this species in Oakley Park, Cirencester, produce a fine effect, as the tall stems, closely set along the edges of a woodland glade, contrast well with the background of foliage. Douglas fir will undoubtedly make, in time, magnificent avenues, as it grows fast and to an enormous size; but it must be planted in a sheltered position. The three cedars

AN AVENUE OF POPLARS IN ESSEX.

are also capable of forming splendid avenues in many parts of the country, but they are very sensitive to wind and remain stunted in exposed situations. Many kinds of silver fir and pine may also be planted in avenues, but for a long time the effect of their regular conical form is unpleasing. Thuya gigantea, a fast-growing tree, is open to the same objection.

The number of smaller trees, both broad-leaved and coniferous, that may be tried where large and stately avenues are not desired, is very great, and no list of them can be given here. Nothing need be said about modes of planting except to reiterate the warning, rarely listened to, that small trees are always preferable, and on that account three and four year old transplants of most species ought to be used.

When planting, the most important consideration is the choice of the proper species for the soil and situation. Generally speaking, an avenue looks best when all the trees in it are of one species; but in long avenues the soil is apt to change in character, causing uneven growth. The Long Walk at Windsor illustrates this point well. It was planted in 1680 throughout its entire length of nearly three miles with English elm only. The result is splendid as regards the pos-

THE FAMOUS WELLINGTONIA (SEQUOIA GIGANTEA) AVENUE AT STRATHSFIELDSAYE.

Digitized by Google

of the avenue next the Castle, where the soil, loam about 10ft. deep, admirably suits this species. Here the trees attain an immense size, many rising to 120ft., with gigantic boles 15ft. in girth. Farther on, where the soil is clay over gravel, and beyond the double gates, where it is heavy clay, the trees are much smaller, and many have died at various times and been replaced by elms of different varieties. The result is most unsatisfactory. In such a case a different species should have been used for the poorer soil or the avenue discontinued.

Attention must be paid to the local climate, the important factor being the strength of the prevailing wind. In the greater part of Ireland and of the western side of Great Britain, trees susceptible to wind, like cedars, Douglas fir, larch and chestnut, should never be planted in avenues. Altitude, of course, is another important factor in limiting the choice of trees.

The width of the avenue and the spacing of the trees are points which must be studied at the time of planting. Short avenues should be narrow in order to preserve the necessary perspective. The correct proportion in a short avenue between width and length has been laid down as one in ten, thus in an avenue 100yds. long the width ought to be about 10yds. The trees in this will eventually close up and form an overhead canopy, a desirable feature in a short avenue. In longer avenues the proportion of width to length may be less, and the width nevertheless greater, say, 15yds. to 25yds. for avenues 400yds. to 800yds. long. If the sides of the avenue are composed, as is often the case, of two or three lines of trees, the width between these may be the same as the distance apart of the trees in the lines, and may vary from 10ft. to 30ft. or more. This depends mainly on the height which the trees are expected to attain. Trees that will eventually tower into the sky must be widely spaced. Shade-bearers, like beech, spruce and silver fir, may be kept closer than light-demanding trees, like oak, chestnut and pine.

I will now give the distances of some successful avenues. In the Long Walk at Windsor, which has two lines of elms on each side, the width of the broad walk between is 50yds., and the distance apart of the side lines and of the trees in the lines is 30ft. This allows a great height to be attained, 120ft. for the trees in the best section of the avenue, next the Castle. The distance apart corresponds to forty-eight trees per acre for elms 240 years old, and may be compared with the figure for oak grown on the best soil in a Continental forest, namely, fifty-six trees per acre for oaks attaining 120ft. at 160 years old. The Wellingtonia avenue at Wellington College consists of two single lines 25yds. apart, the trees being 50ft. apart in the lines. Allowance is here made for the great height, perhaps 150ft., which will ultimately be attained. Lime avenues are usually narrow. The fine one at Burghley Park consists of four lines, of which the two inner are 20yds. apart, each being 10yds. distant from its outer line. The trees in the lines stand at 18ft. apart.

FLOWERS in the MIDLANDS at the ROYAL SHOW

IT is not always appreciated that flowers and plants have a varying interest much influenced according to the locality in which they are seen. It is this, among other reasons, that causes the "Flower Tent" of the horticultural section of the Royal Agricultural Society of England, which moves the site of its Show to various parts of the country, always to be among the most popular items to be seen in a vast display of many acres of exhibits, mostly agricultural.

While yet exhibitors at Leicester were congratulating themselves on the beautiful and cool weather, a gale sprang up and partially wrecked one of the large tents, blowing roses and sweet peas, orchids and carnations into confused heaps. This occurred on the last day of the Show, the principal victims being Messrs. Alex. Dickson and Sons, Messrs. Stuart Low and Co. and Mr. C. Engelmann, whose groups were destroyed.

In consequence of the prize moneys offered in numerous classes by the Royal Agricultural Society, in contrast to the Royal Horticultural Society, they secure keen competition and better groups and collections than are sometimes seen in London. The sweet peas were exceptionally good, but little separating the first three entries. Messrs. Robert Bolton and Son led, with Messrs. J. Stevenson and Messrs. E. W. King and Co. second and third respectively. The first-named arranged their flowers in baskets, including a fine mass of Comrade (rosy buff) and Wembley (mauve). Poppy, always looking well, and Royal Sovereign were in the other groups. Exquisite peas in non-competitive classes were included in the groups of Messrs. Sutton and Sons, Messrs. James Carter and Co., Messrs. Andrew Ireland and Hitchcock, Messrs. Alex. Dickson and Sons, and Messrs. Toogood and Son of Southampton.

DELPHINIUMS AND HARDY FLOWERS.

No wonder that the delphinium is one of the most popular of summer flowers. The variety Mrs. Townley (immense, Cambridge blue) and Smoke of War, representing the light and dark blues, with the nearly white Moerheimii, are a good combination. These varieties were shown by Messrs. Blackmore and Langdon and Messrs. Artindale and Sons, as well as in the hardy flower groups of Messrs. Harkness and Sons and Messrs. Gibson and Co., who had massed banks of lupins, pyrethrums, etc., relieved with tall spikes of eremuri.

A fine piece of work in the shape of a model terrace garden with excavations was carried out by Messrs. Bakers. It occupied the whole length of one tent.

The best display of irises, arranged with a water garden and a fine variety of nymphæas (water lilies), was that by Messrs. Kent and Brydon.

GROUPS OF ROSES.

Among other roses which were well shown in the winning groups, were Mrs. H. Morse, brilliant carmine and rose; Souv. de Claudius Pernet, sunflower-yellow; Souv. de Georges Pernet, Indian red or cochineal old rose; Queen Alexandra, larger than ever; and America and Columbia, two roses which stood in good condition throughout the four days' Show. The above were included in the competing groups which secured awards in the following order: Messrs. A. J. and C. Allen, Messrs. Harkness and Co., Messrs. W. and J. Brown, and Mr. Thomas Robinson; groups in this class being also put up by the Burbage Nurseries, Messrs. English and Son, and Mr. C. Gregory.

Mention should be made of Lady Roundway in the non-competitive group of Messrs. B. R. Cant and Sons, a new shade of copper and apricot; and of Roselandia, the new yellow (recently illustrated in THE GARDEN), exhibited by Messrs. Stuart Low and Co., which is a great improvement on Golden Ophelia. Messrs. Daniels and Messrs. William Lowe and Son also had fine roses.

STOVE AND GREENHOUSE PLANTS.

Large groups were shown by Messrs. Cypher and W. A. Holmes. Orchids and tall crotons, ixoras and dracænas made a riot of colour displayed in an artistic style, which is the opposite of crowding plants into a bank. Calceolarias, streptocarpuses from Messrs. [illegible] and Son, with wonderful begonias from Messrs. Blackmore and Langdon, were in faultless condition.

CARNATIONS.

Nigger (crimson), Sheila Greer (yellow and fiery red), Laddie (salmon) were the principal varieties in Mr. C. Engelmann's group. Topsy (crimson, an improved British Triumph), White Pearl (sweetly perfumed) and Eileen Low (salmon) were the best three varieties in the group of Messrs. Stuart Low and Co.

Coral Glow (orange-apricot), Edward Allwood and the Dianthus Allwoodii figured in Messrs. Allwoods' display.

The Border Carnations of Mr. H. Lakeman were a beautiful clean lot, including The King (crimson) and Elaine (porcelain white).

FRUITS.

One of the most popular sections of the Show was that of fruit. Messrs. Laxton Brothers excelled themselves in a comprehensive collection of strawberries, in which the high quality Laxtonian and the new variety The Duke were prominent.

The fruit trees in pots of Messrs. G. Bunyard and Co. arrived in fine condition. Apples, pears and plums, as well as ripe Cherries Early Amber and Bigarreau Noir de Guben, were attractive; some ripe fruits of apples stored from last year were also interesting.

AWARDS.

The Royal Agricultural Society's judges made the following awards:

First-class certificate to Messrs. Blackmore and Langdon for Delphinium The Shah, immense spikes of which carried mauve and blue flowers of unusual size.

Award of merit to Messrs. Alex. Dickson and Sons for Rose Scarlet Glory, one of the brightest red hybrid tea roses for the garden yet seen; and Saltaire, an addition to the dark crimson hybrid teas.

Award of merit to Messrs. Stuart Low and Co. for Carnations Eileen Low, a deep salmon, and White Pearl, both of which have been illustrated in THE GARDEN.

DELPHINIUM DAY AT VINCENT SQUARE

ALTHOUGH cherries should have been the main feature at the Royal Horticultural Society's Hall, Westminster, on July 8th, there was only one small exhibit. Delphiniums were shown in large quantities by many firms.

Two outstanding delphiniums on Messrs. Blackmore and Langdon's exhibit belonged to the ranunculus section. Although popular many years ago, these plants are seldom seen nowadays. Lieut. Vasseur is a distinct novelty belonging to this section. The flowers are double and blue in colour, suffused violet, the spikes stiff and the blooms beautifully spaced. This variety attracted a great deal of attention. Another sort was a seedling, a very curious flower of pale pinkish mauve. An outstanding variety on this exhibit was The Shah (see "New and Rare Plants.")

The aptly named Bluebell was very prominent on Mr. T. Carlile's exhibit. Other good sorts were Harry Smetham, gentian blue, faintly suffused rose; Lord Derby, palest violet, the outer petals blue—this variety is semi-double.

Messrs. Kelway and Son showed their new variety, Sansovino, which is a double sort of smoke purple colour with blue edges.

Mr. H. J. Jones put up a large exhibit which was excellently arranged. Two notable sorts were The Alake and the Rev. E. Lascelles.

Delphiniums and irises were shown by the Orpington Nurseries Company. Among the irises, White Queen and Royal Purple were notable, and prominent varieties of delphiniums were The Alake and Queen of Delphiniums. This firm also showed many seedlings.

Messrs. R. H. Bath, Limited, showed many delphiniums, including Sir Douglas Haig, Dusky Monarch, King of Delphiniums, and Van Veen's Triumph, a fine pale mauve sort. They also showed gladioli.

Mr. W. Wells, jun., showed delphiniums, including King of Delphiniums. He also showed numerous other hardy plants.

A large exhibit of delphiniums including The Alake, Rev. E. Lascelles, Heavenly Blue and King of Delphiniums, were shown by Messrs. Waterer, Sons and Crisp, Ltd.

Mr. Amos Perry showed delphiniums and a large batch of Coreopsis grandiflora Perry's variety.

Mr. F. G. Wood had a collection of hardy plants in which Delphinium Van Veen's Triumph and Campanula Jenkinsæ were very conspicuous.

A collection of lilies was staged by Messrs. R. W. Wallace and Co. The almost black L. Martagon Catanii and L. M. dalmaticum were very prominent.

Messrs. Barr and Sons showed delphiniums, Morina longifolia and the beautiful Phlox Snowdon, together with other hardy plants.

Exhibits of hardy plants were very numerous and were shown by the following firms: Messrs. G. Stark and Son, the Chalk Hill Nurseries, Messrs. R. Tucker and Sons, Mr. G. Reuthe, Messrs. Daniels Brothers, Limited, Messrs. Gavin Jones and Ingwersen, Messrs. M. Prichard and Sons, Messrs. Carter Page and Co., Messrs. Rich and Co., the Misses K. and E. Hopkins, Messrs. Harkness and Sons, Messrs. Reamsbottom and Co., and Mr. H. Hemsley.

The new rose Roselandia and carnations were shown by Messrs. Stuart Low and Co. White Pearl and Eileen Low were two outstanding carnations.

Roses were shown by Messrs. D. Prior and Son, Messrs. Easlea, Messrs. B. R. Cant and Sons, Messrs. William Lowe and Son, Messrs. Chaplin Brothers, Messrs. S. McGredy and Son, Messrs. Frank Cant and Co., and the Rev. J. H. Pemberton.

Mr. Douglas showed border carnations, and the following were conspicuous sorts: The Grey Douglas, Bookham Clove, Queen of Cloves and Bookham Yellow.

ROSE BEDFORD CRIMSON WHICH SECURED THE CLAY CUP

Carnations and Dianthus Allwoodii, including some new sorts, were shown by Messrs. Allwood Brothers. Mr. Engelmann also showed carnations.

An exhibit of stove and greenhouse plants was staged by Messrs. L. R. Russell and Co.

An interesting exhibit of cacti was shown by Miss S. S. Thompson.

A fine lot of strawberries was displayed by Messrs. Laxton Brothers. Their new sorts, Laxton's Latest and Omega, are excellent. Laxton's Latest is of immense size and of excellent flavour, and Omega is of fine quality. They also showed a new red currant called Laxton's Perfection. The berries are of good size and of excellent flavour. It is a very prolific variety. On one stalk exhibited there were twenty-seven berries. This currant should soon become very popular.

The only exhibit of cherries was shown by Sir Charles Nall-Cain. The fruits were of good size and colour.

A fine collection of Melon Gunnersbury Park was shown by Mrs. Leopold de Rothschild. The fruits were of exceptional size, very aromatic and showed great cultural skill. They were awarded a cultural certificate.

The Clay Challenge Cup was offered for a rose of good form and colour not in commerce, possessing the true old rose scent such as may be found in the old cabbage or Provence rose, in General McArthur, etc. The scent known as "tea rose" was not, for this competition, to be accounted as true old rose scent. Competition was fairly keen, and the cup was awarded to Messrs. Laxton Brothers for a rose named Bedford Crimson (H.T.). It is a cross between Château de Clos Vougeot and Richmond, and is a velvety crimson sort that is very pleasing in the bud state. There were some other good sorts shown, including the following:

FRAGRANCE (see "New and Rare Plants").

WM BOWYER (H.T.) of a bright velvety crimson, suffused maroon, and the fragrance is pleasing.

DUDLEY (H.T.) is a crimson maroon sort, but, unfortunately, hangs its head. It is a small flower and throws its blooms in clusters.

KITTY MEHANE is a good white slightly tinted flesh. It has an excellent fragrance.

SALTAIRE is another notable variety.

NEW AND RARE PLANTS.

ATRAPHAXIS BILLARDIERI.—This is a curious knotweed-flowered shrub. Award of merit. Shown by the Director, Royal Botanic Gardens, Kew.

BEGONIA ALBATROS.—A double-flowered white sort of the largest size and of fine camellia form. The habit of the plant is good. Award of merit.

BEGONIA LADY ANN.—A double-flowered sort of salmony-rose colouring. This variety belongs to the camellia-flowered section. The petals are large and gauffered. Award of merit. Both the above begonias were shown by Messrs. Blackmore and Langdon.

CAMPANULA ZOYSII.—This pretty little lavender-blue alpine species with curiously constricted blossoms was shown literally covered with flowers and buds. Award of merit. Shown by Messrs. R. Tucker and Sons.

CARNATION (BORDER) SULTAN.—A dull orange-apricot sort of large size, but not of very pleasing form. It is not a fragrant variety. Award of merit. Shown by Mr. J. Douglas.

COREOPSIS AURICULATA SUPERBA (lanceolata type).—A very cumbersome name for such a beautiful flower. This plant is apparently a good form of C. grandiflora, with two rows of petals which are conspicuously blotched with brownish-crimson at their base. The flowers are almost the same size as the grandiflora type. Award of merit. Shown by Messrs. Ladhams, Limited.

DELPHINIUM THE SHAH.—A stately variety of mauve and blue colouring. The spikes are very fine and the blooms well placed. Award of merit. Shown by Messrs. Blackmore and Langdon.

Digitized by Google

LILIUM DUCHARTREI (FARRERI).—The species was originally known as L. Farreri when it received an award of merit. It is the most delicately beautiful of the Martagon section. The flowers are pure white, heavily spotted chocolate with conspicuous golden anthers. First-class certificate. Shown by Lieutenant-Colonel Messel.

ROSE FRAGRANCE.—This is an aptly named H.T. variety of crimson colouring. At its best it is a shapely and pleasing sort. It appears to vary somewhat. Award of merit. Shown by Messrs. Chaplin, Limited.

ROSE LORD LAMBOURNE.—A large-flowered variety of obviously Pernetiana parentage. The flowers are large but not at all shapely. It is a yellow sort, irregularly suffused with rose towards the edges and is not fragrant. The only thing that appealed to us was the foliage.

VUYLSTEKEARA EDNA VAR. NORMANDY (Miltonioda Harwoodii × Odontioda Charlesworthii).—This attractive trigeneric hybrid, connecting the genera cochlioda, miltonia and odontoglossum, bore a branching spike of thirty-one medium-sized flowers and buds, of reddish-scarlet colour, the comparatively large labellum lighter, and the column rose tinted. Award of merit. Shown by Messrs. Charlesworth and Co.

NEW FRUIT.

HANWAY BERRY.—Judging by the sample shown and without tasting it, it appears to be a poor form of the loganberry. Of course the habit of the plant may be good, but we have not seen it growing. It is to be sent to Wisley for trial. Shown by Mr. G. W. Colenutt.

ROSES & SWEET PEAS AT BOURNEMOUTH

AT the Summer Show held in the spacious pavilion of the Town Hall on Tuesday and Wednesday, June 24th and 25th, some excellent displays of flowers were staged, the awards being made by Mr. McKellar of the Royal Gardens, Windsor, and Mr. Cobb of the University College, Reading. For the second year in succession, Mr. Elisha J. Hicks of Hurst won the challenge cup with a magnificent collection of high-class rose blooms, staged in faultless style. Second and third positions were taken by Mr. Arthur Radmore of Bournemouth and Messrs. S. Bide and Sons. The space occupied was 15ft. by 4ft. For the second season, also, Mr. Hicks won the challenge cup for twelve blooms, distinct, and numerous other prizes. Mr. A. E. Usher (gardener to Sir Randolph Baker, Bt.) won the challenge cup for a display of sweet peas, space 12ft. by 4ft. This exhibitor also won many other prizes. A challenge cup offered for the best display of florists' floral devices on a space 20ft. by 4ft. was won by "Leonards," Bournemouth. Messrs. Stuart Low and Co. were awarded a gold medal for fine collections of orchids and carnations. Medals were also awarded to the following firms: Messrs. Baker's, Wolverhampton, for herbaceous plants; Messrs. Maurice Prichard and Son of Christchurch, for herbaceous plants; Mr. Arthur Radmore, for roses; Messrs. S. Bide and Sons, for cut herbaceous flowers, etc.; Mr. T. K. Ingram of Parkstone, Dorset, for liliums and cut herbaceous flowers. The exhibition was a success, the competitive classes being well filled.

FORTHCOMING EVENTS.

July 22.—R.H.S.'s Fortnightly Meeting.

July 23.—Morley Paxton Society's Meeting.——Hayward's Heath Horticultural Society's Exhibition (two days).

July 24.—Royal Botanic Society's Meeting.

MORE ABOUT THE SUMMER ROSE SHOW

(*Continued from page* 487.)

AMATEURS' CLASSES.

Throughout this division the roses reached a high standard of excellence, and in the decorative classes great skill and taste were displayed. The Amateur Champion Trophy was won by Mr. R. C. Turnbull, who staged thirty-six exhibition blooms, which were characterised by good typical form, large size and fresh colouring. The very best were J. G. Glassford, Lady Barham, Mabel Drew, W. H. Walsh, Captain Kilbee Stuart and A. Hartmann. Captain N. J. Thorpe was a good second in this large class, and his most prominent varieties were Edith Cavell, Lemon Pillar, Lady Barham, Gladys Holland and J. G. Glassford.

The class for twenty-four blooms was of equally high merit, and the same competitors as in the larger were successful. Mr. Turnbull included W. H. Walsh, Souv. de Claudius Pernet, St. Helena and Lady Inchquin; while Captain Thorpe had lovely blooms of Mrs. George Norwood and Mrs. R. D. McClure.

Mr. J. E. Rayer, who with a magnificent bloom of Mme. Jules Gravereaux won the silver-gilt medal and the Boyes Cup, was first with twelve distinct exhibition roses. He also included Mrs. Henry Morse, Mrs. H. R. Darlington and Mrs. F. Hobbs. Mr. F. H. Fieldgate was second. Mrs. Henry Balfour was the most successful among growers of fewer than 1,000 plants, and her very best were Molly Bligh, Mrs. Charles Russell and Nellie Parker.

The best two baskets of exhibition roses were shown by Mr. C. C. Williamson, who included the lovely tea rose W. R. Smith. Showing Mrs. C. Lamplough, Mr. E. H. Rigg was first with one basket.

The extra classes of exhibition roses induced very good competition. The chief first prize winners were Mr. H. H. Claydon, Mr. E. H. Rigg, Mr. Rogers and Mr. J. F. Owen. In the classes for amateurs who have no paid assistance Mr. W. G. Bawbridge won the Nicholson Cup, and Mr. E. W. Edwards won the Elisha Hicks Cup, both with very good specimens. Other first prize winners in this section were Mr. G. J. Ingold, Mr. R. de V. Pryor and Mr. W. J. Panckridge, who all staged really splendid blooms.

Tea roses are always well shown by amateurs at Regent's Park, and this year the Rev. F. R. Burnside won the trophy with delicately beautiful blooms of such splendid sorts as S. de Pierre Notting, W. R. Smith, Mrs. Hubert Turner and Innocenté Pirola. Captain J. Thorpe was a good second with White Maman Cochet, W. R. Smith and S. de Pierre Notting. Mr. W. E. Moore had the best nine varieties, and with very good specimens Mr. Rogers was first with six blooms.

One wonders how often Mr. H. R. Darlington has won the first prize with a representative group of roses, but he has rarely done so with a better collection than this year. His very best vases were of Mme. Edouard Herriot, Mme. Butterfly and Los Angeles of the dwarfs, and such cluster varieties as Milkmaid Gardenia and Moonlight. Mr. G. Marriott was a good second, and he included General McArthur, Old Gold and Louise Baldwin. Mrs. E. M. Wrightman was first in the smaller group class, and her prominent varieties were K. of K., Independence Day and Mrs. Henry Bowles. Dr. M. Lacroze with a novel and effective arrangement, won the Dixon Davies Cup.

Mr. Gordon Baker and Mr. F. C. Wiseman were the chief prize winners with baskets of decorative roses; while Mr. A. C. Turner, who included splendid vases of Irish Fireflame, General McArthur and Killarney won the Mattock Cup. In this section Mr. F. C. Slaughter was deservedly very successful.

There were so many good exhibits in the class for three blooms each of eight varieties that the judges awarded an additional prize. The first prize set included excellent trios of Bessie Chaplin, Lord Charlmont, Columbia and Mme. J. Zouche.

THE ARTISTIC CLASSES FOR AMATEURS.

In this section some classes were well contested. However, in many cases these dinner-table decorations were somewhat overdone. On the whole the blooms were quite good.

Mrs. Courtney Page was first for a table decoration. In this case Mme. Butterfly was employed. Miss E. Griffith was second with Golden Ophelia. This table was much too crowded.

Mrs. Courtney Page was also first in the class for a dinner-table decoration, in which the flowers had to be grown and staged by the exhibitor without assistance. The Nickerson prize (a piece of plate) goes with the first prize in this class. Mrs. Courtney Page employed roses Emma Wright and Sunstar. Mrs. Oakley Fisher was second. Her arrangement was somewhat novel. The roses—Irish Elegance, Old Gold and Irish Fireflame—were placed in cut glass vases and the vases were linked up with cut glass chains. In our opinion this exhibit was superior to that which received the first prize.

Mrs. A. D. Ruff had rather an original table decoration, but one not worthy of emulation. This exhibit was awarded first prize. Mrs. H. Barton was second, but her table was too crowded. Mrs. Courtney Page was third.

For a bowl of mixed cut roses Mrs. Courtney Page was first and Mrs. H. Barton second. Mrs. Courtney Page's basket was quite good.

For a bowl of cut blooms Miss M. E. West was first with Mme. Butterfly and Mrs. Colston Hale was second with rose Mrs. Oakley Fisher. We considered the latter bowl better than that awarded first prize.

For a vase of cut blooms Miss M. E. West was first with Mme. Butterfly. Mrs. Courtney Page was second, but the vase was missing.

In the class for lady amateurs who had never won a prize Mrs. F. Peters Wood was first with a bowl of Ophelia, and Mrs. G. M. Kessell was second.

In the open artistic classes Mr. L. R. May was first with Ophelia. The table was far too crowded. Miss M. Foden was second.

For a bowl of cut roses Miss M. Foden was first with Mme. Butterfly and Mrs. C. A. Tisdall was second with Ophelia.

SUMMER TREATMENT OF CLIMBING PLANTS AND ROSES.

THE beauty of these, also flowering shrubs, may be enhanced or marred by the treatment they receive during the summer months. Those of rapid growth and trailing habit require much more attention than others of a bushy habit. Clematises, when grown on a large scale, require a lot of attention as regards training, especially with a view to the even disposal of the young shoots so that the latter will not form a dense mass near the top of the specimen. All flowers that have faded should be removed, cutting away the flower stems close to the harder wood. The honeysuckles require equally close attention. While the shoots are young it is not a difficult matter to disentangle them and tie them in thinly, but when they are hard and set in winter, scarcely anything can be done to them then in this direction.

Solanum jasminoides is a favourite outdoor climber in the southern counties, and much of the effectiveness of the plant is in its training. All the young flowering shoots should be allowed to depend loosely and gracefully, several feet in length, from the harder wood—the only part of the plant that should be made secure to the wall or other form of support. Many lateral shoots of the vines used as outside climbers should be cut off, as, late in the year, they are rarely ornamental and often become an eyesore through mildew.

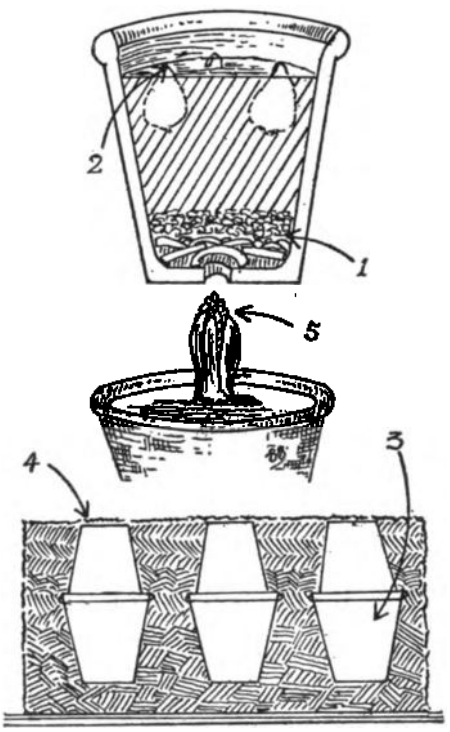
From climbing roses, spent flower trusses and also all old wood causing overcrowding should be cut. The former should be cut from flowering shrubs, including rhododendrons.

PRIMULAS AND CINERARIAS.

Of these two kinds of plants the primula will withstand most heat without harmful effects, but neither require much heat during the summer months. The cultivator who possesses a movable frame and can turn it to face due north has an advantage over the one who is obliged to grow his young plants in a permanently fixed frame facing due south. In the latter case it is found necessary to shade during a great part of the day, and the semi-darkness has the effect of weakening the growth. The plants in the frame with a north aspect, consequently, receive more light, less sun, and so grow more robustly. These are items of general management, and very important ones, too. Now we come to the consideration of daily treatment. In the case of the frame facing south, shading is a daily matter unless a permanent shade is applied. I believe in such: one made of whiting and milk—better still, buttermilk. The permanent shade should be light, sufficient for ordinary weather, then extra covering material can be put on in very hot weather. In no case should any plants be allowed to become potbound, but be re-potted always in good time, as premature flowering is then avoided. Fibrous loam and leaf-soil in equal proportions, with a 7in. potful of old mortar rubble and a 3in. potful of bone-meal to each bushel of the above combined parts, will prove a good general compost. Pot the plants fairly low down, then they will not require support; do not pot too firmly, water very carefully, and do not be afraid to admit plenty of air night and day.

POTTING EARLY BULBS.

The work of cultivating early bulbs in pots comes fresh to us every year; and every year there are new cultivators.



The Roman hyacinth and early-flowering narcissi are not difficult to grow if three or four points of some importance are attended to. These bulbs thrive in a light compost, and one of the chief ingredients should be rotted leaf-soil; to this add good mellow loam and some coarse sand. For both hyacinths and narcissi similar treatment as regards potting and after-management will do. If we take a 6in. pot we may place, at least, five bulbs of hyacinths and four of narcissi, respectively, in each one. No. 1 shows sound drainage; No. 2, the right position of the bulbs when potted; No. 3 shows the pots under ashes in a cool position outside; and No. 4, empty inverted flower pots put on to prevent the ashes interfering with the new growth and flower stems; No. 5 shows the stage when the plants should be moved from the ashes to a cold frame, there to be gradually exposed to full light and air.

VEGETABLES TO SOW NOW.

The advantages of raising vegetables from seeds sown in July had not been generally realised till the last few years brought to light the work of expert cultivators in this respect. But what the latter have done, nearly everyone who possesses a garden can do now. There are some exceptions, such as soils and situations, but readers may soon decide as to whether serious difficulties stand in the way or not. The main principles to follow are sowing the seeds where the resultant plants are to remain till fit to be used, and sowing the right kinds and varieties. Moderately thick sowing is right; the young plants must be thinned out at an early stage of growth and before they weaken those to be retained. The work of thinning should be carefully done and the retained seedlings forthwith watered if the soil is at all dry. Early-maturing varieties of the kinds selected should be sown. All kinds of soil, not previously manured this year, will require some well rotted manure—the light soils most, the heavy ones least.

RIPENING MELONS.

Melons require very careful treatment to bring them to a perfect finish, as really satisfactory fruits cannot be procured on plants lacking in health. From the seedling stage the plants should be grown in a firm bed of soil, the latter being on the heavy rather than on the light side. Up to the stage when the fruits begin to ripen—to crack around the foot-stalk, and to give off that delightful aroma—the plants will require plenty of tepid water, diluted liquid manure and a very moist atmosphere, especially at closing time. Daily syringings of the leaves will be beneficial also. A circle, about 6ins. across, around the stem of each plant will need to be kept free from direct watering; some water will drop on the soil within this circle from the plants when the latter are syringed, but will quickly dry up. The quantity of water should be lessened when the first stage of ripening is noticed in the fruit, and it will be beneficial to leave the top ventilators open a little all night. Each fruit should be supported by a net, in houses, and by inverted flower-pots in frames.

GEORGE GARNER.

CORRESPONDENCE

WISLEY GARDENS.

SIR,—The article and the Editorial in your issue of June 28th on the Wisley Gardens were very reassuring, and all the more so because you gave value and proportion to your praise by some discerning yet kindly criticism. Two years ago some of us were somewhat alarmed at the contrast between the rapid recovery, after inevitable war neglect, shown by many private gardens and the evidences of the halting recuperation which met us at Wisley. That, you show, is now of the past or nearly so; and with so large an area of varied cultivations it is no wonder that a thorough overhauling and replanting of the rock garden has not yet been reached.

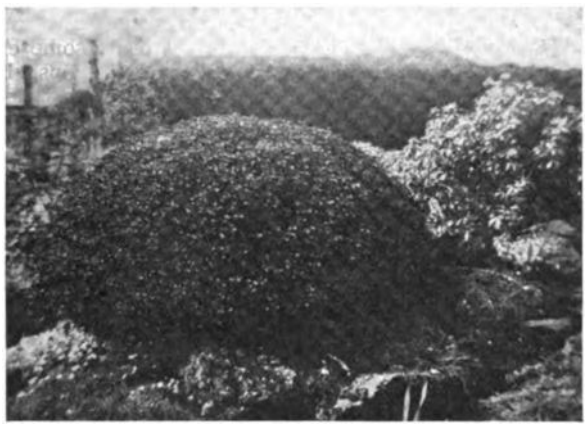
But the most valuable of your remarks are those on what the chief purposes of Wisley are, or should be. It is all-important that Wisley should aid the Fellows of the Royal Horticultural Society in the choice, grouping, cultivation and situation of plants, shrubs and trees by exhibiting all the most choice, and especially the most recently introduced varieties of leading species. It should be a well ordered and well sustained living museum where valuable notes can readily be taken. It is also important that by a due development of the propagating department it should be in a position to supply Fellows with struck or seedling examples, especially of desirable yet little-known and popularised species and varieties, the demand for which is as yet too small to induce nurserymen to stock and offer them. A well developed section on these lines would aid both amateur gardeners and nurserymen. Those of the former class who like to try a new thing, who are ready to test such introductions as promise to succeed in their soil and circumstances, would thus know where they were likely to get what they want, either by free distribution or, as I suggest, by reasonable payment. Such plants would be seen and appreciated by their visitors, who would ask their nurseryman for them and so lead to their being put on the market. As you rightly say, "Wisley should be the great distributing centre for all new importations." That eminent position it has not yet reached. But it quite well may do so, and, indeed, I see signs that it is being aimed at. I found a much better selection of rarer sorts of plants in this year's distribution list. I picked out a little batch, and not only were they sent to me, but almost every example was of adequate size and showed cultural care. I feel that Wisley is on the up grade, that its committee and director are full of purpose of their own, and are eager to receive suggestion where it is as sound in itself and appreciatively yet diffidently offered as it was in your recent issue.—H. AVRAY TIPPING.

FAILURE OF THE SCOTCH LABURNUM.

SIR,—Some of your correspondents during May or early June remarked upon the wealth of bloom produced by the laburnums, hawthorns and flowering crabs this year. I agree with that entirely, but noted one striking exception in a common, usually free-flowering tree. There are many old trees of the Scotch laburnum (Laburnum alpinum) in the grounds of the Chelsea Hospital, which are in bloom on the occasion of the great Flower Show there at the end of May in early seasons, but otherwise are only in bud at that time. This year I could see only one tree that bore half a crop or less of still unopened flowers. In order to determine whether the trees at Chelsea were exceptional or not, I kept an eye upon all the other trees known to me in different gardens, and noted only one bearing a full crop of flowers. L. alpinum is easily recognised by its larger, more shiny leaves, longer racemes and later-flowering habit than the common laburnum.—J. FRASER.

GENISTA HISPANICA.

SIR,—This, the Spanish gorse, is flaming at present (June 18th) in my rockery at Duns. It was planted a few years ago and has never been clipped, as one would think judging from the photograph which I am sending. The whole shrub is so densely covered with golden yellow blossom that not a twig or spine can be seen. It is hardy and most attractive. When the sun was shining to-day I thought I had never seen a more beautiful shrub.—(Dr.) J. MACWATT.



THE SPANISH GORSE. GENISTA HISPANICA.

A WONDERFUL PROFUSION OF SAXIFRAGA HYPNOIDES.

THE SUMMER ROSE SHOW.

SIR,—The beautiful Show of the National Rose Society at the Botanic Gardens on June 27th will long be remembered. The genial weather after heavy rains produced blooms of the highest quality, and on the whole their arrangement was successful. There were so many fine blooms and such a number of varieties that it would be difficult to differentiate them one from the other, so I simply name a few of the newer and newest varieties that appealed to my taste, and hope others may do the same, as reporters cannot quite look at the flowers from the point of the amateur who thinks even more of his garden plot than the exhibition tent. First of all, then, it seemed to me that Mabel Morse was by far the most satisfactory of the yellows, entirely superseding Golden Emblem.

Lady Roundway, a rich orange, was another rose of striking beauty this fine season. Ruth, with its lovely shadings of rose and soft orange, was also most desirable in my eyes.

Red Roses.—Hortulanus Budde seemed more brilliant and satisfying as a *red* bedding rose than ever, and the newer Saltaire, so deep in colour and so very fragrant, seems a real advance to the ideal crimson garden rose Mrs. H. Winnitt (red) also struck my fancy *very* decidedly. But it was when we came to the white roses that the giant Everest, the fragrant Marcia Stanhope, and Snowdrift with its soft shell-like petals, all made appeal to one's sense of beauty and purity that could not be resisted! Who will choose between them till we have seen them grow?

I should again wish to make my protest against the excessive use of one or two well known roses in the competition for table decorations. One might be tempted to think Irish Elegance, Fireflame and Mme. Butterfly to be the only roses in existence. The sameness year by year is extreme, and judges should strike out a line for themselves and say that such and such a flower after many prizes should be handicapped. As it is, it is simply a premium on one or two exhibitors and their roses, and deadly dull.—AN OUTSIDER.

SAXIFRAGA HYPNOIDES AS AN EDGING PLANT.

SIR,—The enclosed photograph, which will probably be of interest to your readers, shows a border of Saxifraga hypnoides growing in the garden of Mr. Van Guisen of Birkenhead.

I do not think it is generally known that Saxifraga hypnoides makes such a beautiful edging for drives, walks, etc.—WILLIAM PEMBERTON.

BLUE FLOWERS.

SIR,—I find that the plant referred to by me on page 483 as Cynoglossum appeninum is now scientifically known as Solenanthus apenninus.—HERBERT MAXWELL.

THE SHOWING OF OUT OF-SEASON VEGETABLES.

SIR,—We are now in the throes of horticultural exhibitions, and there will be staged vegetables the chief features of which will be their abnormal size. Others, like parsnips, celery and leeks will appear at the summer shows also—out of season, and worthless, at such a period, for consumption. The cook has no use for them thus early, and no self-respecting chef would presume to include them in his menu.

If we ask those responsible for compiling schedules for this season of the year why vegetables which have no real value from a culinary point of view before late autumn or winter are considered, we are told that it has always been the practice to include them among vegetables for competition. In other words, societies are fettered by

Digitized by Google

tradition and are afraid of deviating from a customary rule, and, as a consequence, the judge is often led to give decisions for the largest vegetables, simply because the saving clause, "fit for table," has been purposely or inadvertently omitted. We have seen this exemplified more than once in the case of vegetable marrows. The worst feature, perhaps, about the showing of immature and out of season vegetables is that, in order to obtain the requisite number of roots, many have often to be lifted before a selection can be made. Anyone who has had experience in providing material in the classes for the vegetables mentioned knows very well that promising roots are frequently disturbed, all to no purpose. Is it not time that some modification should be made in the schedules among various societies? We have been witness of much waste in regard to the vegetables specified that are admitted to be of little or no service in the kitchen until cold or frosty weather has made them sweet and tender. It seems to me that the cook, and not the gardener alone, would be better able to appraise the worth of many vegetables staged at exhibitions; but so long as prizes are offered, no matter whether the show is in August or November, competitors will be forthcoming. We have seen rows of parsnips and leeks upset "to find the best," and the value of the prizes did not compensate the grower for his losses. Judges could "a tale unfold" if they were free to do so; but they have a schedule placed in their hands and are bound by conditions contained therein.

Some chrysanthemum societies are now seeing the wisdom of encouraging competition for vegetables at their November exhibitions. This is a step in the right direction. We are frequently meeting with those who, after some years of exhibiting, tell us that "the game is hardly worth the candle." So far as showing out-of-season vegetables we quite agree.—W. LINDERS LEA.

ANSWERS TO CORRESPONDENTS

FLOWER GARDEN.

Sweet Peas Diseased (L. H. C., Ross-on-Wye).—The peas are affected by the mildew Erysiphe Martii. There has been nothing wrong with the mould or compost. It is possible that the sticks may have been the means of conveying something from the rubbish referred to, to the plants, but the most likely cause is drought. Apply water copiously two or three times and forthwith mulch heavily with any kind of litter or light material. To prevent undue strain on the plants cut the flowers frequently.

Plants to Flower in the Open from May to October (S. A. E.).—The following will be found suitable for the purpose in view: Achillea The Pearl, Anemone japonica, asters in variety, Campanula latifolia, Centaurea montana alba, C. m. rubra, Chrysanthemum maximum, Coreopsis grandiflora, doronicum, Gaillardia grandiflora, gypsophila, Helenium superbum, Iris germanica, I. sibirica, Lychnis chalcedonica, phloxes in variety, pyrethrums (both single and double), Scabiosa caucasica and Statice latifolia. Seeds should be sown as soon as they are ripe. Great care is needed, or there may be much disappointment. An inexperienced amateur would be wise to buy seedlings. More success may be obtained in the case of Michaelmas daisies.

Delphiniums and Lychnis Unsatisfactory (F. A. B., Glos.).—The leaves are attacked by a rust fungus, the result of cold, wet weather. All affected foliage should be collected and burned forthwith, then there may not be any such trouble with the second crop of delphinium blooms. Spraying with a solution of Bordeaux mixture would have been beneficial earlier in the season, but is of little use now.

Violas Diseased (W. M. F.).—The wireworm is not the cause of the death of the violas, but the fungus Æcidium violæ. Possibly the disease may have been conveyed to the ground in the leaf-soil so freely used. Next year select a new quarter for the violas and apply 6 oz. of lime per square yard to the soil this autumn at digging time. Practically nothing very beneficial can be done to the border and plants now, beyond applying a surface mulch of loam and wood ashes, a peck of the latter to five of the loam.

TREES AND SHRUBS.

Roses and Clematises for an Archway (J. E. H.).—Of clematises, Jackmanii would be suitable, or Lady Northcliffe or Nellie Moser. Three good roses for such a position are American Pillar, Blush Rambler and Seagull. An alternative set might consist of Alberic Barbier, Hiawatha and Sanders' White. Rosa Moyesii is a wonderful plant in flower and fruit and would be worth trying, but it does not succeed in all gardens.

Shrubs as a Screen for Garden Seat (J. E. H.).—If you could start with a good sized plant of Rhododendron yunnanense or R. Augustinii they would make a good show. Failing these, the new Dipelta floribunda is very showy, so is Viburnum plicatum.

Treatment of Daphne Cneorum (H. N., Guildford).—The behaviour of Daphne Cneorum is puzzling. In some gardens it grows and flowers profusely without any special attention. Another garden with apparently similar conditions and every attention the plants fail. Do not cut back the straggly stems, but place stones on them, with a little loam and leaf-mould between. If this is done each year the plants eventually grow on low mounds, the stones conserving moisture about them, which the daphne roots like.

Dying Back of Trees and Shrubs (H. J. B.).—Except in the case of tall trees being actually struck by lightning, we have seen no evidence to trace the dying back of branches or the collapse of entire trees to lightning or electric discharge. It may be due to one or other of a variety of causes. Failing disease, of which our correspondent says there is no evidence in his case, injury to the cells may arrest the flow of sap to a twig or branch. We feel sure the death of the small standard quince is due to the plant being grafted, and the union between the stock and scion has failed. Silver-leaf disease is very widespread among trees and shrubs and not easy to trace in the early stages. Xanthoceras sorbifolia is very subject to coral spot. The trouble may not be apparent at first, but will show later when the disease develops. It must always be borne in mind that many trees and shrubs in our gardens are the inhabitants of very different climatic conditions and soils. That all should thrive in perfect health in entirely different surroundings is impossible. Checks from various causes weaken the constitution, and failure in some cases follows.

FRUITS UNDER GLASS.

Melon Plants Not Flowering (I. N.).—Plants raised from seeds saved from sound fruits should bear both male and female flowers freely and more surely than those raised from layers or cuttings. Probably the plants have been allowed to grow luxuriantly in a too loose soil, without any stopping. The main stem should be stopped when at a length of 2ft. Side shoots will grow and, when the latter are stopped, sub-laterals, and on the latter, respectively, the fruits should appear, also plenty of male blossoms.

Nectarine Stone Splitting ("Regular Reader").—This defect is constitutional in the case of a few varieties of peaches and nectarines. With really good cultivation it may be reduced to a minimum. As the young fruits are setting and beginning their first swelling, care should be taken to avoid any check being given through chills—extremes of temperature. The chief point to observe, however, is the due liming of the soil every autumn. A light sprinkling of lime or a peck of old mortar rubble per tree being very beneficial. Also, do not overcrop.

FRUIT GARDEN.

Young Apples Falling (J. B. L., Surrey).—If our correspondent will cut open some of the affected fruits she will, no doubt, find the cause of the trouble inside. The grubs were found in the specimens sent. These are the maggots of the weevil Anthonomous pomorum. The weevil punctures the unopened flower bud and lays one egg in each hole, but attacks many buds; the grubs enter the young fruits at various points and eat their way to the centre. It is often called Tinea corticella. Once inside the fruit the latter is ruined. The only preventives we know of are spraying and the treatment generally as used against the codlin moth.

Strawberries Mildewed (J. F. Y., Suffolk).—The fruits were attacked by mildew while very small; it interfered with the normal swelling to a great extent, but its deadly effect was not observed till the fruits softened for ripening, then they began to rot. In many districts there has been similar results this year. In future, place the litter to the plants at an early stage—before the flowers open—and use a light, clean material.

Apples and Cherries Unsatisfactory (T. B., Galashiels).—The apple branches are affected by the fungus Fusicladium dentriticum. All foliage that falls should be burned forthwith, and after the leaves are all off spray with the Bordeaux mixture, also in spring before the buds open. The cherries are not diseased, but the soil lacks lime; the latter should be applied at the rate of 1 peck per tree in November, spread evenly on the surface and lightly forked in.

Gooseberry Mildew (D. L.).—The fruits sent are affected by the gooseberry mildew to a serious extent. We strongly advise you to uproot the bushes and burn them. Early in the autumn apply 8 oz. of gas lime per square yard when the soil is dug, and leave the latter in a rough state throughout the winter, cropping again next spring, but not with gooseberries. Plant young, healthy plants in another quarter of the garden.

About Cherries, Pears and Madonna Lilies (D. C.).—The cherry trees are undoubtedly suffering from over-dryness at the roots. The soil, too, may lack lime. The latter should be applied in the autumn, the water and a good surface mulch now. The pears are attacked by the fungus Fusicladium dentriticum. Spray with Bordeaux mixture when the leaves fall and in spring several weeks before the buds open. The Madonna lilies are affected by the fungus Ovularia elliptica, which spreads very quickly and soon destroys leaves and stems. We are not able to give a certain remedy, as, so far, none is known. The safest plan is to lift the bulbs, wash them, dust on flowers of sulphur and transplant quickly into another part of the garden.

Digitized by Google

About Gooseberry Leaves and Potato Flowers (W. G. S.).—We are not able to find any disease to account for the spotted appearance of the gooseberry leaves; but if our correspondent poured liquid manure on the bushes a few weeks ago it may be the cause. Syringe the bushes well with clear water every fine evening for a week or so. The potato flower buds of some varieties do not develop, but fall off every year. Possibly they have fallen through sudden dryness of the soil and great heat combined. The fact that they have dropped will not have any effect on the tubers.

MISCELLANEOUS.

Onions Unsatisfactory (F. H., Wells, Som.).—The base of the plant has been pierced by a maggot, the larva of a grey-coloured fly. The grub cannot be killed without destroying the plant; indeed, the grubs do kill many plants, but a light sprinkling of salt on the soil and a free one of soot weekly will help to preserve the plants now free. The others should be pulled up and burned, together with old onions left in the store or shed, the covering material, dust, etc. Wood ashes containing pieces of charcoal should be scattered on the soil between the rows. The fly will lay its eggs on the charcoal portions and the larva will perish as it will not have food available.

Pond Water Muddy (H. S. B., Bucks.).—As long as our correspondent retains ducks in the pond the water will remain muddy. This would be the case even if the bottom and sides were of cement and not of clay. Ducks always stir up water and discolour it. Where there is not, actually, any mud, they leave the pond with wet feet and, returning, convey mud to the water in this way.

Names of Plants.—(F. M. D.).—Rose Mme. Alfred Carrière.——(W. R. J.).—1, Common China rose; 2, Crimson Damask rose.——(H. M.).—Limnanthes Douglasii.——(G. J.).—1, Olearia Gunnii; 2, Pernettya mucronata. —— (F. A. S.). — Bulbinella Hookeri.

Catalogue Received.

Messrs. Sutton and Sons, Reading.—Flower and Vegetable Seeds for Summer and Autumn Sowing.

GARDENING OF THE WEEK

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbage.—Early cabbages are much appreciated and to make sure that plants will be ready for autumn planting, the seed should be sown now. The following varieties will be found to give satisfaction and should come in for use from April onwards almost in the order in which the names are given. Flower of Spring, Harbinger, Little Gem, Sutton's Main Crop and Tender and True.

Cauliflower.—The variety Walcheren, if planted on ground from which early potatoes have been cleared, should come in for cutting in October. Level down and rake the ground before planting, and well water the plants in the evenings should the weather be dry. Spent crops should be cleared from the ground.

Lettuce. — Seedlings getting crowded should be thinned out and the thinnings or plantlets set out on other borders. Should dry weather prevail the transplanted seedlings should be sprayed each evening until re-established.

Parsley.—This vegetable requires a long season of growth and those who wish to have a good supply for winter should sow seed now. Borders from which early potatoes have been cleared would be a suitable place for the crop, but on no account choose poor soil for parsley. The following are tried and well known varieties: Champion Moss Curled, Methven's Green Gem and Myatt's Garnishing.

THE FLOWER GARDEN.

Carnations.—The season is fast approaching, which we might call a second spring for the gardener, as not only the layering of carnations should be taken in hand, but many cuttings also require to be inserted. Layering, although simple enough, requires to be done carefully and with judgment on the part of the operator.

Cuttings.—A few geraniums from stock plants should be inserted either in boxes or pots filled with moderately sandy soil made firm. When the cuttings are inserted they should be well watered, then set in a cold frame, very little water should be given afterwards—except when the weather is exceptionally dry—until the cuttings show signs of growth. Lavender and Nepeta Mussini cuttings should be set in sandy soil in frames, after the cuttings are thoroughly watered the frame lights should be closed, and the cuttings occasionally sprayed, and shaded at all times from bright sunshine for a few weeks.

Gladioli are handsome plants when in flower and should be securely staked now—if not already done—so that the heavy flower heads will not get broken down.

Delphiniums.—Seedlings should be set out in the open border in lines 1ft. apart and 6ins. allowed between each plant in the lines.

East Lothian Stocks.—Those who wish an early display from these choice and charming stocks should sow seed now, pricking the seedlings into boxes, or cold frames, as soon as they are fit to handle.

THE HARDY FRUIT GARDEN.

Gooseberries.—This year the bushes are bearing a good crop of berries and now the ripening stage is fast approaching nets should therefore be spread over, and where no permanent framework exists, it is quite easy to set up poles and stretch strong string from pole to pole over which the nets can be placed.

FRUITS UNDER GLASS.

Apples.—Trees in the orchard house with ripening fruits, such as Red Astrachan and Mr. Gladstone, likewise Cullin's Golden Gage and Czar Plums should be allowed plenty of air.

Vines.—In the late house grapes should now be colouring and increased ventilation should be given. Still continue to damp stagings and pathways on very bright days.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Cabbage.—From now till about the middle of August seeds may be sown with a view of producing an indispensable crop next spring. It is advisable to make two or three sowings, the principal one being made early next month. At present the variety April and Ellam's Early should be chosen, and the maincrop may consist of these kinds, with Harbinger, Wheeler's Imperial and Early Offenham. It is a good plan to sow the seeds broadcast, but for the sake of cleanliness lines 1ft. apart are best if the seeds are sown thinly. If the soil is dry, give the drills a good soaking of water a few hours prior to sowing the seeds.

Parsley.—A constant supply of parsley is needed in most gardens, and for winter use a few lines of seeds should be sown. It is most convenient if the crop is placed near a path, so that the stalks may easily be picked without getting on the soil when it is wet.

Spinach.—A good breadth of the prickly-seeded kind should be sown in lines 12ins. to 15ins. apart, and when large enough thin the seedlings to 6ins. A site ought to be chosen which will not be very wet during the winter months, and the soil should be kept free from weeds, the hoe being used occasionally whenever the ground is sufficiently dry.

THE FLOWER GARDEN.

Heucheras.—These are charming plants for both the border and rock garden, and they are readily raised from seeds which may be sown at the present time. Named varieties, however, are increased by cuttings; the growths are severed from the parent plant, placed in lines in a cold frame, and the lights kept on till the cuttings are rooted. Sandy soil is best, and a little shade will be needed for a week or ten days. When rooted the lights should be removed and the plants kept well supplied with water. The old plants may be destroyed, as young examples produce the finest flowers.

Campanulas.—This is a most beautiful race of plants, the majority of which are ideal for the rock garden. Choice and special varieties are increased by division and cuttings, but many of the species can be successfully raised from seeds. These may be sown now in pans containing light soil, and when the seedlings are large enough prick them off in pans or boxes. Give the protection of a cold frame during the winter and transplant in their flowering quarters next spring.

Budding.—The budding of roses should be carried out during the present month and, judging from the weather we have experienced, the bark will run easily and the operation will be successful. A number of other subjects, such as prunus, thorns, etc., may also be budded.

THE HARDY FRUIT GARDEN.

Summer Pruning.—This is a much debated subject that now calls for consideration, and if moderation is the rule no doubt much good is done. Trees on walls and pergolas should be dealt with first, and later trees a few weeks hence. The leading or terminal shoots are allowed to go unchecked, but the lateral growths are cut back to four or five leaves from their base.

Figs.—Trees growing at the base of walls must be examined occasionally, and if the soil is at all dry a thorough soaking of water should be afforded. Tie in any shoots that need it, and other growths should be stopped at the second leaf. Prevent overcrowding by removing a few of the shoots at their base.

Loganberries —This plant rarely fails to produce a good crop, and for this reason it should be represented in every garden. The new shoots are growing freely, and they should be tied loosely to the wires to prevent them being injured. Cut out all weaklings and only retain enough new growths to take the place of the old ones later on. Superfluous suckers of raspberries can also be removed. T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR GREENHOUSE AND CONSERVATORY.

Gloxinias, as they pass out of flower, should be stood out in cold frames and kept supplied with water until the foliage shows signs of dying down. At this stage water should be withheld, gradually drying the plants off and then storing them in a warm dry building. Plants raised from seed early in the year should be potted on as they require it, growing them under fairly cool conditions. Plants raised from seed this season should prove very useful towards the end of summer. Begonia mite should be guarded against by the use of the sulphur vaporiser.

Begonias. — Tuberous-rooted varieties raised from seed this season and planted out in cold frames should now have made quite good plants. Some of them should be lifted and placed in pots, as such plants prove very useful towards the end of summer, making a good succession to the earlier batches grown from dry tubers.

Begonia semperflorens, of which there are many fine varieties, is largely used for summer bedding in the south. In the colder parts of the country it is very useful for greenhouse decoration. Even where used for summer bedding it is very valuable for the greenhouse during late summer and autumn.

Calceolaria violacea.—This distinct species is very useful for conservatory decoration, and young plants that have finished flowering, if potted on into 8in. pots, will make fine specimens for next year. They should be grown in a perfectly cool greenhouse, or may be stood outdoors where they can get some shade during part of the day. Young plants rooted during the spring, if placed in 6in. pots about this time, will make good plants for the stages next year. This calceolaria makes a fine specimen where it can be planted out in a cool conservatory.

Amphicome Emodi is a beautiful plant which is by no means common. It is easily propagated at this time by means of cuttings, which root readily in a cool greenhouse, standing the cutting pots under a propagating glass. This plant only requires cool greenhouse treatment at all stages of its cultivation; and good flowering specimens can be produced in 6in. pots.

Amphicome arguta, which is more or less hardy in the south, may, in the cooler parts of the country, be grown for the greenhouse. It has pretty pale pink flowers. Although it is by no means such a choice plant as the other species, it is easily propagated either by means of seed or cuttings.

Isoloma hirsutum is very useful for the greenhouse, as it can be had in flower more or less all the year round. It is increased by means of the scaly rhizomes, or even by means of cuttings, which root readily at any time in a warm propagating case. If grown on in 6in. pots in an intermediate house it makes fine plants for the stages. The individual plants remain in flower for several months. If potted on into 8in. pots, it makes specimens 3ft. high, which are very useful for standing in the beds. This plant succeeds quite well in any good potting compost.

Fabiana imbricata.—This pretty shrub, although hardy in the south and west, requires the protection of a cool house in the colder parts of the country. It makes an excellent pot plant, and forms a large specimen if it can be planted out in a cool conservatory. It is easily propagated at this time by means of cuttings inserted in pots containing sandy soil and stood under a bell-glass in a cool greenhouse or cold frame. Its successful cultivation presents no difficulty, as it grows freely in any good potting compost.

Dendromecon rigidum is a beautiful yellow poppywort from California. Although more or less hardy in the south and west, it should be much more generally cultivated in the cool conservatory, where it should be planted out in a light sunny position in a well drained bed. This plant is propagated by means of cuttings, using the short twiggy shoots for this purpose. Dibble them in pots containing sandy soil and stand them under a bell glass in a cool house. This is by no means an easy plant to propagate. J. COUTTS.

Royal Botanic Gardens, Kew.

HORTICULTURAL COLLEGE, SWANLEY

GARDEN PARTY FOR EMPIRE VISITORS.

A NUMBER of visitors from the Dominions were invited to the Horticultural College, Swanley, for Thursday afternoon, July 3rd. Those who came were received by Kathleen Viscountess Falmouth, chairman of the Governors of the College, by Dr. Barratt, the Principal, and by other Governors. Unfortunately, there was a good deal of rain during the afternoon, so that the visitors were unable to spend as much time inspecting the college grounds as would have been possible on a fine day. Just now the garden is at its best, the lawns and flower borders are particularly attractive, and the recent wet weather has tended to keep up the fresh appearance of the decorative part of the grounds.

The visitors were entertained to tea in the main assembly hall of the college, and afterwards visited the biological, chemical and botanical laboratories adjoining. The chemical laboratory was enlarged recently, and is now a good-sized, light and airy room, in which a class of about thirty students can work. Increased accommodation for study in the sciences allied to gardening has been necessary since the college started the preparation of students for the London degree of B.Sc. in Horticulture. Most of the present students are still working for the college diploma in horticulture, but some have started on the degree course.

A feature in which the visitors showed much interest was the jam factory. This has been rebuilt lately to give increased space for the making of jams, jellies, pickles, preserves, etc., and for the bottling of fruit and vegetables.

Swanley College was very glad to welcome representatives from the Dominions and Colonies, some of whom had heard of the college and were already interested in the work. The college has always something of an international character; not only have a number of students from all parts of the Empire passed through and returned to their homes with a special interest and training for work on the land, but there are usually also a number of women students from other European countries. The need for more women specially trained for the various branches of work on the land is particularly felt in many parts of the Empire. For instance, in Ontario there is splendid scope for trained educated women willing to work on the land, and these are specially desired by those who have to do with the entrance of women into the Province. The markets are good, and the land needs development in this way. Institutions for giving training to women on these lines would probably serve a useful purpose if they could be established in various parts of the Empire, as was suggested by some of the visitors at Swanley on Thursday; for instance, in New Zealand or even in India. It would be a step towards the advancement of such a scheme if students from the places concerned could come over and study the principles of the subject here, so that they would be available for the staffing of their own colleges in due course. And Swanley could help in this way. It is interesting to notice also how the making of a garden and the direction of the work to carry it on often falls to the lot of the European woman in the newer Colonies, such as Kenya. Native labour is to be had, but needs detailed direction; and here some knowledge of fundamental principles on the part of the women will add much to their chances of success and contribute to the happiness of the busy white man in the outposts of the Empire.

ORCHARD GARDEN WOODLAND

Vol. LXXXVIII.—No. 2749 Saturday, July 26th, 1924 Price THREEPENCE

The Kelway Colour Border

is planned for continuity of bloom as well as colour effect. Your garden is of enduring beauty from early Spring to late Autumn, and so continues for several years, as a result of the minimum of cultivation, expense and attention.

These Colour Borders have evolved from many years of experience, and clients get the advantage of securing, amongst other subjects, the world-renowned Kelway Specialties in Hardy Plants.

Send dimensions of space to be filled, and the effect required, stating aspect and soil, and asking any questions.

We are only too pleased to advise.

BEAUTY

SEVERAL times I have been asked what I consider to be the most beautiful flower, and what am I to answer?

It would be as easy to answer, What is beauty? And that is a most difficult definition. In a dictionary there will be some attempt at a definition, something which expresses a combination of qualities which delights the sight or other senses; but that carries one a very little way in the understanding of beauty.

Beauty is not a matter which can be talked about in cold blood, for the very essence of beauty excites, and no two people see beauty to the same degree or with the same mental excitement. We are told in the "Arabian Nights" that the Persians see beauty in a grossness of form which is merely disgusting to European eyes. Further east a twisted line, at least in plants, satisfies the senses.

> On rocky plateau with no earth to hold
> Were trees and shrubs, gnarled and very lean.
> Roots and stems stretched to grip the stone:
> Humped and bent, they writhed like a coiling snake.

In their hardness and angularity of line the Oriental is sometimes very cruel.

What is so often forgotten is that beauty rarely depends upon the individual thing which is admired: Surroundings make or mar the beauty of a plant: weather, company, the mental and psychical state of those who look are all great factors, but I stoutly maintain that beauty is always more overwhelming when seen in silence and even more so in solitude, for the power to see beauty is the most personal of our possessions and beauty is often too sanctified to be discussed. Sometimes we are carried away by our emotion and ponderously exclaim our ideas, but it almost always falls on deaf ears. What right have we to suppose that we have such abnormal powers of expression, or that we see beauty eye to eye with the rest of mankind?

I have been rather carried away by a subject on which I feel very strongly, but it is all preliminary to stating a feeling I have that people rely too much on others for stocking and designing a garden. After all, our garden is a personal thing. If we are satisfied with it and consider it beautiful, that is surely all that is necessary: nobody else will see it with the same eyes that we do. There is no truer proverb than "Too many cooks spoil the broth," and I hate proverbs, for they are mostly true and usually fly back in one's face like a boomerang. I could cap in with another: "People who live in glass houses should not throw stones," for I am constantly called upon to give advice, and often give it gratuitously, which is wrong.

Many factors are required to make a garden beautiful; a certain amount of open space, perhaps shaded, in which to be peaceful, the suitability of plants to the lie of the ground, for ground as flat as a pancake may be beautiful if carefully planted, the appropriate use of colour, some prefer it in broad patches and some in mere suggestions; but in every case the idea of beauty is personal.

There are, however, four precepts which I am bold enough to state:

Acquire a plant if you think it beautiful and never mind what other people say; that is, if beauty is your ideal—and the corollary:

Never take a plant which you have been told is beautiful and you do not agree with that opinion.

Never place a plant in position when you are in a bad temper or unwell or cold or unhappy, for your sense of beauty is frozen. Wait till you are at peace with the world.

Always trust your own judgment in your own garden. It belongs to you. If anything goes wrong it is your own fault, and you will know better the next time.

These four precepts I believe in thoroughly to-night, for I have been reading Mr. Waley's Translations of Chinese Poems and they make me feel displeased with the world in general. No doubt to-morrow I shall feel cock-a-hoop and will fall back into my old fault of giving advice, gratuitous and otherwise.

THE MARKETING OF FLOWERS

BY GEORGE MONRO.

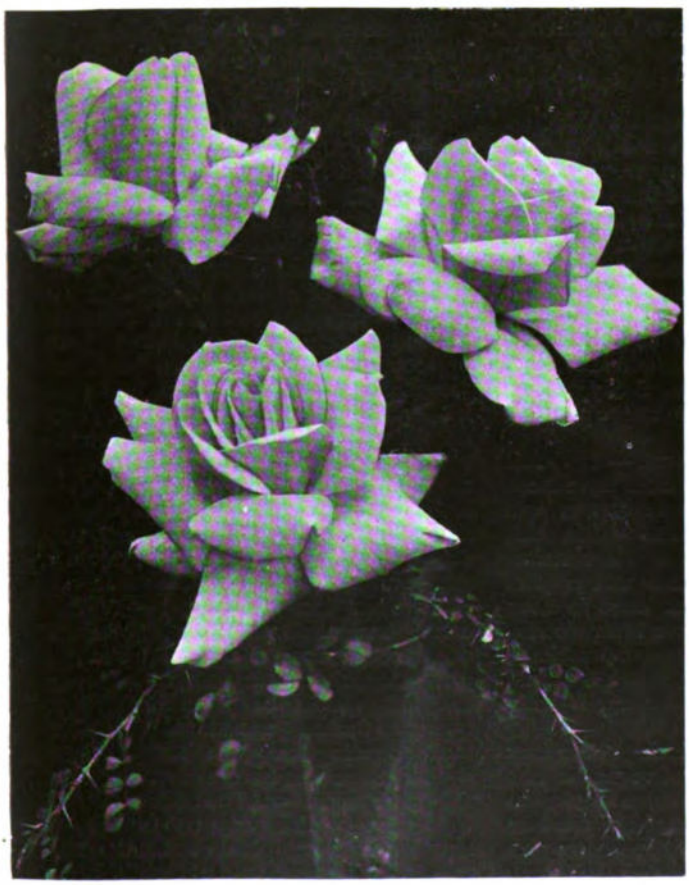
(*Continued from page* 305.)

THIS ARTICLE GIVES ONE AN IDEA OF THE ENORMOUS ADVANCE WHICH HAS BEEN MADE IN FLOWER PRODUCTION DURING THE LAST FIFTY YEARS. VARIETIES COME AND GO YEAR BY YEAR AND EACH SEEMS TO SURPASS THE OTHER IN QUALITY AND EXCELLENCE.

OF the variety of products which come into and are distributed from Covent Garden, few have shown a more rapid increase than cut flowers, the production of which in ever-increasing quantities has been brought about by the universal desire for flowers in one form or another. In my first article (in the issue of May 3rd) I dealt principally with the main sources of production, and a few points in an endeavour to account for this progress will, perhaps, be interesting.

It has, of course, been largely assisted by the improved purchasing power of the people, there being now possibly a hundred buyers able to afford a few flowers instead of—as formerly—a limited number who bought them entirely as a luxury; but this changed position would probably not have come about without the vast improvements in varieties as well as in the quality of the bloom itself. Methods of growing have also entirely changed for the better. In the early years of the forcing of roses the only heat used was the spontaneous heat from manure beds, whereas now, hot water and steam, through pipes of various sizes and in positions best suited to the variety being forced, are used. In this connection one outstanding advance has been in the forcing of carnations. Originally roots were lifted from outside, forced during the winter under heat, and the roots thrown away after they had yielded one crop. Nowadays they are expected to give continuous flowering for three years before being replaced by new plants.

Again, it is difficult to say in which species, variety or class the greater advance has taken place. In my former article I touched on the better quality, increased length of stem and improved range of colours of the present-day perpetual-flowering carnation as against those marketed up to the end of the nineteenth century; but many other flowers have made equal strides.



OPHELIA. A GREAT FAVOURITE OF THE MODERN FLORIST. ALTHOUGH CRUDE IN FORM THE OLD ROSES HAD A DIVINE FRAGRANCE.

AN ENGRAVING BY MONNOYER SHOWS THE TYPE OF ROSE POPULAR IN FRANCE ABOUT THE YEAR 1720

Primarily, without doubt, comes the rose, in which the first big step forward was the introduction of Mme. Abel Chatenay, raised in 1895 by the well known French grower Pernet-Ducher of Orleans. The next step of importance was in 1900, with the introduction of Liberty by Messrs. A. Dickson and Sons (of Hawlmark, Ireland). A steady run of improvements followed: Richmond, another red, but a little ahead of Liberty in some respects, raised in America by the E. G. Hill Co. in 1905; Ophelia, exceeded only in beauty by the better-coloured Golden Ophelia, raised by Messrs. B. R. Cant and Sons in 1917, succeeded by other long-stemmed varieties, with a range of colours almost comparable to carnations, all of which has enabled the rose to well uphold its position as the national flower, in spite of the fact that not a few of the new varieties have their origin outside this country.

Next to the rose I take the chrysanthemum. The blooms of thirty-five to forty years ago would scarcely be saleable nowadays to a street trader. The tiny Mrs. Carey and the varieties of the Dixon and Rundle type were first followed by the group comprising Elaine (white), Source d'Or (bronze), Triumph and the improved Desgrange (white, pale yellow and deep yellow), most of them marking an enormous advance. These have practically all disappeared, due to the efforts of

Digitized by Google

some half a dozen men, who appear to pass their lives in the endeavour to raise better varieties year by year.

The Framfield group, including Heston White and Winter Cheer, have revolutionised the supply available for Christmas and the New Year, while the very many Cranford varieties have not only added six weeks at the beginning of the season, but have greatly improved the varieties and qualities available from September and October, so much so that the flowering season, which twenty years ago was from September to mid-December, now begins early in July and runs to the end of January. Another big advance has been in the method of disbudding. Thirty years ago nearly all chrysanthemums sent to market were in the form of the natural spray, a few only being rather larger through having had the side buds picked off. The improved varieties have lent themselves to the development of size as well as colour, and now we are able to market a complete range—from the natural spray right up to the enormous exhibition bloom.

Sweet peas have shared in the general advance. The old Countess of Radnor (mauve), Princess Beatrice (pink), King Edward (red) and Dorothy Eckford (white), with their 7in. or 8in. stems, and generally a maximum of two flowers on each stem, have given way to a range capable of a standard 18in. to 20in. stem bearing from four to as many as six flowers each of greatly improved beauty, a list of which fills a good many pages in the Sweet Pea Society's Annual. No visitor to the Royal Horticultural Society's annual show at Chelsea could miss the magnificent exhibits put up by such firms as Messrs. Dobbies, Dickson, Ireland and Hitchcock, Bolton and a number of others.

In the herbaceous section, again, the present types represent such an advance on their predecessors of a generation or more ago as to be almost different plants, as, for instance, pyrethrums, delphiniums and gladioli, and in addition to this great improvement in the varieties better methods of bunching and packing have been evolved, and the combined result—with the undoubted hold that flowers have on both high and low—is such an increase in bulk as would have staggered market people of thirty years ago.

The range is so extensive that I will only mention a few of the principal ones, the turnover of which is so large nowadays as to run (in each instance) into hundreds of thousands of bunches in each season. Statice (incana, white; sinuata, mauve; and latifolia, blue) probably takes first place, with wallflowers—supplies of which have been much extended of late years by consignments from Scilly, the western counties and the Evesham district—coming next. Stock runs the last fairly close in bulk, comprising such well known strains as Princess Alice and East Lothian (whites), Beauty of Nice (pink) and Queen of the Belgians (mauve). Gypsophila would take next place (home supplies of this are supplemented by early supplies from France), the best varieties of the home-produced being elegans grandiflora alba and paniculata with its double form. Afterwards, in succession, I should place nigella, Michaelmas daisies, peonies and delphiniums, all showing an almost unbelievable improvement, though I think a special comment should be accorded to the very beautiful specimens of delphinium seen on this market in the past three or four years, confirmation of which I see in my own garden in the many magnificent examples sent me annually by that keen enthusiast and raiser of new varieties, Mr. T. Bones of Cheshunt.

I cannot do better than end by copying the market buyer, who generally completes his purchases by obtaining the necessary foliages to fit in with his bloom. One could write another complete article on foliage alone, such as the various pittosporum types, ornamental grasses, the different kinds of asparagus in all its shades, coloured prunus, the many varieties of spiræa, oaks of different shades—all of these not only used as a contrast or background for flowers but in many cases so beautiful in themselves that florists use them because of their own individual charm.

SWEET PEAS DURING FLOWERING TIME

SWEET PEAS ARE AMONG THE MOST DELICATE AND GRACEFUL OF ALL SUMMER FLOWERS, AND IT IS WELL THAT THE NECESSARY PRECAUTIONS BE TAKEN DURING FLOWERING TIME, SO AS TO OBTAIN THE BEST BLOOMS TO ADORN THE GARDEN.

THOSE who have added some new varieties of sweet peas to their collection will now be examining them every morning or every day to see how they answer expectations. Enthusiasts who have grown them for some years know their flowers at sight and get a thrill of delight when a beautiful new one opens for the first time. He or she will endeavour to define the colour and fix its relationship by comparison with the old favourites, when the distinctions will be seen at a glance. Older varieties that have given good results are always grown because they can be relied upon to give satisfaction under given conditions of soil and treatment; but enthusiasts cannot rest upon their oars, or upon their previous successes, because they know that their favourite flower is always undergoing improvement, and they feel they must be in touch with the newest that is an advance in colour, vigour, number of flowers on a stalk, size, or an advance in any particular character that is an improvement upon the older types. The cult of the sweet pea is truly a progressive one.

Very enthusiastic gardeners in private establishments and others give elaborate details of the treatment required by sweet peas, extending over the greater part of the year, and this deters many who have little time or inclination for the work from undertaking the cultivation of sweet peas; but it has been proved by hundreds of gardeners and amateurs, both before and after they were made a special cult, that, apart from exhibition they could be grown under ordinary conditions of good garden cultivation, such as is given to garden peas. Deep cultivation of the soil is essential, but most old gardens have been trenched, so that deep digging may often suffice if this is done in autumn, say November, and manure given at that time. Early digging allows the soil time to settle before planting time in March or April.

PRESENT REQUIREMENTS.—If hazel stakes or netting of any kind have been used as supports, the sweet peas will mostly take care of themselves in this respect; but if bamboo or other stakes have been used the plants will require a fresh tie every week at least to keep them upright. If they have been planted widely apart the stems may be inclined to produce side branches, but all should be stopped except two or three main stems.

Manures of a stimulating character are those that contain nitrogen in one form or another, and these serve to lengthen the stem and increase the size of the leaves; but it is necessary in the case of sweet peas—or, indeed, any kind of pea—to exercise great caution in the quantity and frequency with which these are applied. This class of plant has special means of collecting its own nitrogen by means of the bacteria in the small nodules on the roots, with which most growers are familiar, and it is essential to success not to demoralise the bacteria or render them lazy by too strong doses or too many applications of certain nitrogenous manures. A dusting of old soot, containing ammonia, may be given before hoeing, or soot water may be used, both being weak and safe. The Dutch hoe should be kept going on either side of the rows once a week, though not a weed may be present. Hoeing retains moisture in the soil during dry weather, prevents it from getting sour during rainy periods, and admits air to the roots, and in all these cases stimulates the growth of the plants.

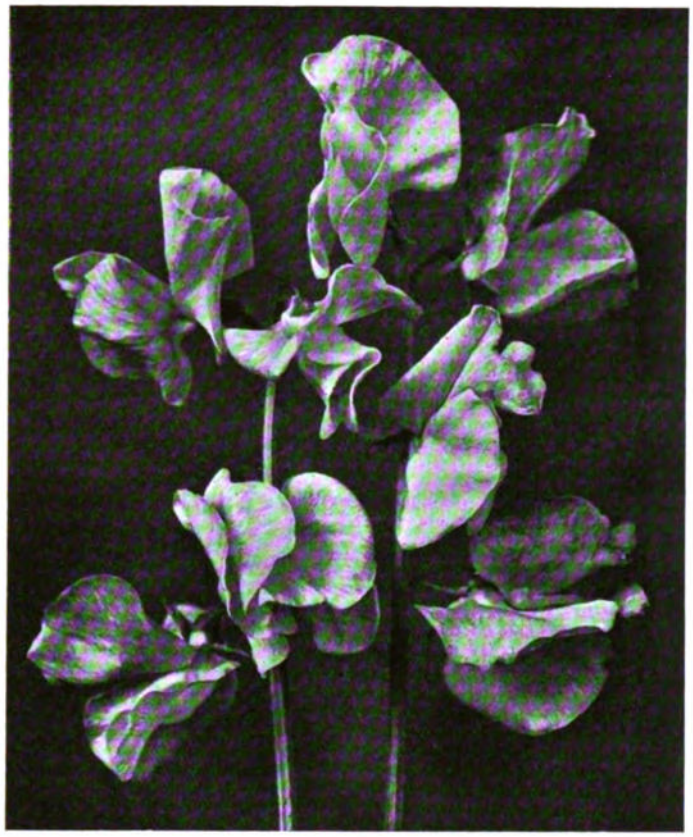
FEEDING AND WATERING.—Watering often becomes necessary during dry weather, because nothing stunts sweet peas sooner than dryness at the roots, and this should be given in unstinted quantity when necessary. Just how much feeding may be necessary will depend upon the natural fertility of the soil and what was put into it prior to planting. The soil may or may not be dry, while the plants are not making satisfactory growth and evidently require feeding. This may be given in the form of superphosphate of lime and sulphate of potash at the rate of 1 oz. to every 6ft.

Digitized by Google

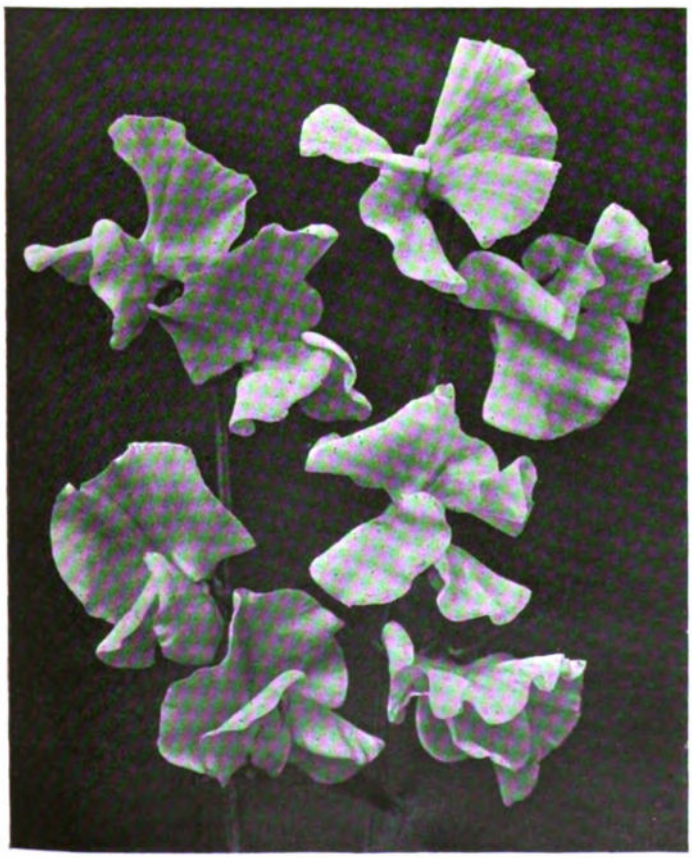
run of the row every eight or ten days, in addition to the soot already mentioned, just before hoeing the ground. They should, of course, be watered in during dry weather, and the ground hoed the following day. If general fertilisers are preferred they should be used in a similar way and in the same sparing quantity. A little and often should be practised instead of strong doses of anything at longer intervals. Well diluted manure water is also a safe general fertiliser. It is very refreshing to the plants to be sprayed with soft rain-water during the early evening of bright and warm days. Even sprinkling the ground with water between the rows during the day has a refreshing effect and prevents the flowers from assuming that tired appearance after sunset which many have observed after a warm day. Gardeners who have warm hothouses under their care, and orchid growers, know the value of this moisture in the atmosphere; and every gardener knows the value of rain as compared with artificial watering, because of the atmospheric moisture.

FIRST-CLASS NOVELTIES.—Even those who secured this year's novelties will be on the look-out for the best of those that will be put at their disposal by the beginning of next year. New varieties are fairly numerous (thanks to the raisers), but a number of them are of super-excellence, and though they may not all live up to their reputation in every garden, a due proportion of them will stand the test of time and place in most gardens. They have been well tested in their places of origin by practical growers well versed in all that pertains to sweet pea culture.

NOVELTIES FOR 1925.—Angele has soft coppery pink standards and lavender-blue wings, which makes a charming combination of colours. A charming bluish lavender is Wembley, that may supersede R. F. Felton. The orange-scarlet of Grenadier is more fiery in tone than Royal Scot and is better in substance. Flambeau is somewhat similar. The Beacon is orange and coral in combination, with erect standards, and is an advance in this class for size. An improvement on the well known Hawlmark Pink is Pink Perfection. An advance in yellows is shown by Majestic, and Mme. Sarah Grand, the latter being deep ivory and cream. The deep salmon-rose of Rose Maiden is an attractive hue. Coraline, orange-cerise, and Venus, salmon pink on a cream ground, are new and choice, which may also be said of the beautiful blue named Bluebird. Shell Pink, Empire (rich rose-pink) and Supreme (rich pink on a white ground) are shades that cannot be overlooked. Ruby is a strong grower, with ruby-carmine flowers; while Mammoth bears four large orange-coloured flowers on a spike.



ROYAL SOVEREIGN, A FINE ORANGE SCARLET.



ONE OF THE BEST MAUVES, POWERSCOURT.

NOVELTIES FOR 1923 AND 1924.—So far the pure lavender of Lord Lascelles has proved of outstanding merit and is very charming for household decoration as well as for exhibition. The rosy-mauve of Shamrock is excellent in its way and will prove useful for household work because it improves in colour after being placed in water. Powerscourt might be described as a rival to Lord Lascelles, inasmuch as it is closely similar in colour, grows strongly and flowers freely. The flowers of W. J. Unwin are of a rich salmon-pink on a cream ground, the first-named shade being the dominating factor of an attractive flower. Yellow is an elusive colour in sweet peas, but the hue of Daffodil, while yet quite young, gives hope for something better. The flowers of Mary Rose might be described as a pleasing shade of rose on a ground colour of salmon. Those who have been unable to get seeds of Royal Sovereign this year will be pleased with a rival to it in Grenadier for next year, because the two will offer greater scope for obtaining really fine flowers in the way of orange-scarlet. The flaming salmon-scarlet of Wizard will furnish a substitute, however for it is really a charming and fascinating flower, of easy culture and free flowering. The white ground Picotee named Youth has many characteristics to recommend it. The flower is large, the colour of the edge is well developed, the stems carry four to five flowers, which are freely produced, beautifully frilled and, above all, are strongly scented. Somewhat older and better known is The President Harding, which has evidently come to stay. The flowers are salmon-cerise suffused with orange, and the variety has an award of merit and a silver medal to its credit. The two last-named varieties are of American origin and may be pioneers of more to come. Many more than the above were put into commerce last year, but those mentioned will furnish a good selection of the lighter and brighter coloured flowers.

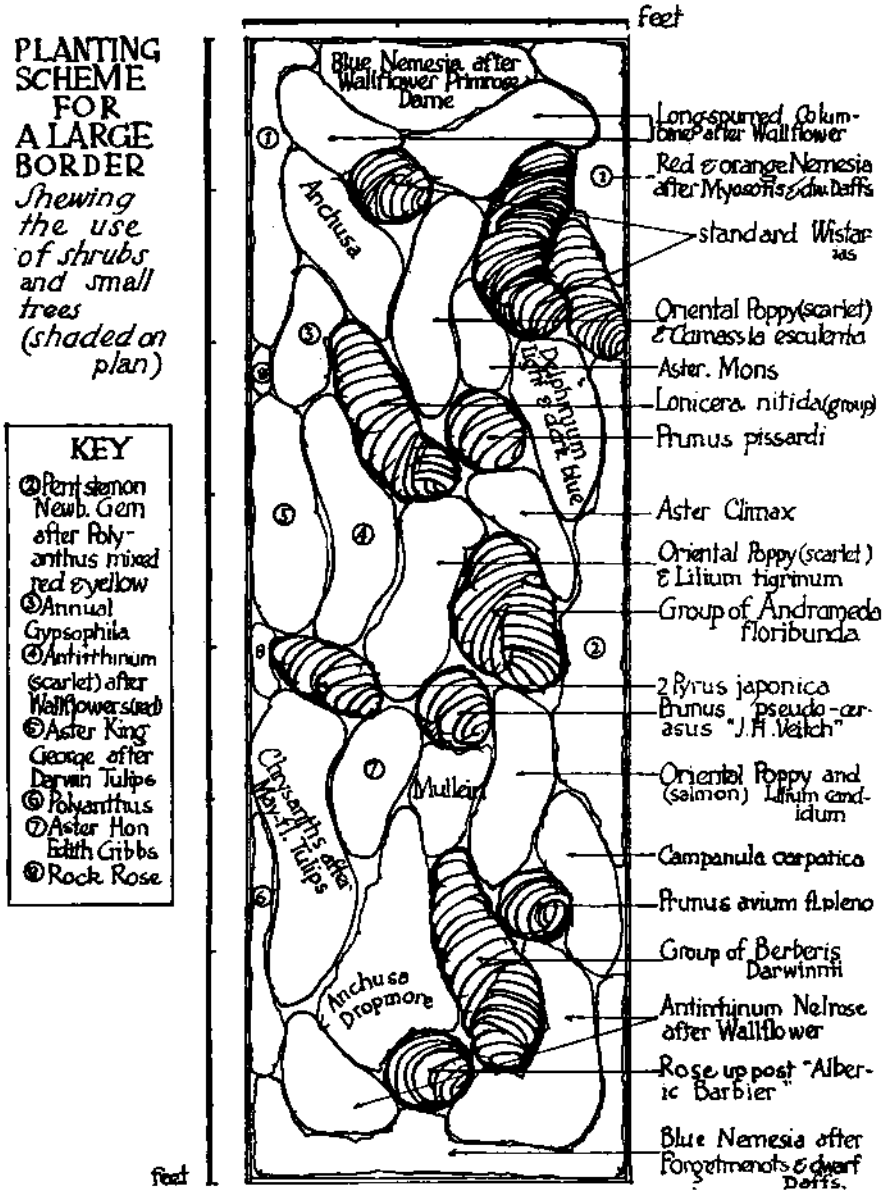
SHRUBS IN THE HERBACEOUS BORDER

IF YOUR GARDEN IS SMALL YOU HAVE NOT ALWAYS ROOM FOR A HERBACEOUS BORDER AND FOR A SEPARATE COLLECTION OF SHRUBS. THIS ARTICLE EXPLAINS HOW BOTH CAN BE COMBINED IN A BORDER.

THOUGH flowering shrubs are worthy of filling a place of their own in the garden, they have also a part to play in the herbaceous border. In a wide border of any kind they are usually an improvement, and clothed at the base with surrounding flowering plants. These should only be planted when the border is 8ft. wide or more, since the space they will ultimately take, and the soil water which their roots will drain, prevent herbaceous



A PLAN OF A SUGGESTED BORDER OF SHRUBS AND HERBACEOUS PLANTS.

in a free-standing border—that is, one without a backing of hedge or wall—they are almost an essential. They give solidarity to the thinness of herbaceous plants and bind the whole scheme together. If some evergreens are chosen, such as Berberis Darwinii, as seen in the accompanying plan, they will forbid the shivering sense of complete barrenness in winter. Our forefathers evidently knew the value of evergreen shrubs in the border; the borders at Brickwall in Sussex, for instance—a sixteenth century garden—have clipped evergreens at regular intervals, their dusky masses plants from growing round their base, and so cuts the border up into so many sections. The effect to be aimed at in this case is that of embedding the clipped shrubs in flowers.

Against some, columbines or annual larkspurs will be grown, for their delicate shape and the poise of their flowers are enhanced by the velvety backgrounds; and between others, Oriental poppies or gorgeous kniphofias, which flame even more brilliantly in such company.

But to return to naturally grown shrubs in the border: Some are unsuitable, since they are not content to act as a foil to plants of lesser stature, but demand attention themselves. Rhododendrons, for instance, are out of place among herbaceous plants, but such as Rhus Cotinus, Prunus Pissardi, Viburnum plicatum, buddleias, Spiræas prunifolia, bracteata, Thunbergii, etc., olearias, ribes, forsythias and others, are extremely useful.

In the case illustrated in the plan, where the border is wide (25ft.) and intended to act as an informal screen to this part of the garden, evergreen shrubs of fairly dense growth are the first necessity, and nothing is more appropriate here than the barberries, the tawny flowers and brilliant autumn colouring making them valuable at all times. Berberis Darwinii is used in this case, but B. stenophylla is also a fine evergreen shrub. Towards the margins of the border, also, BB. Thunbergii and Wilsonæ may be used, though these are deciduous, as well as Juniperus Sabina procumbens (evergreen), skimmia and others. Rhododendron præcox is an effective little shrub to use in the border provided the colours of surrounding spring flowers are carefully arranged with regard to it.

Another advantage of the use of shrubs is that some of the lilies may be accommodated in the half shade of their outer branches.

Where lighter touches are needed, tamarisks (where suitable to the soil), spiræas or clematises and roses on posts give height, some being planted towards the front of the border, where the heights of herbaceous plants may otherwise tend to give a flat look.

The colour, too, must be studied in connection with the planting scheme—Rhus Cotinus, for instance, is very well suited to a border which specialises in different tones of red, though it is useful in many borders not confined to a one or two colour scheme. In the plan shown it might have been used instead of Prunus Pissardi in the middle portion. Both barberries and andromedas would be also useful for their flowers, and with myosotis and pigmy daffodil margins, and groups of wallflowers and May-flowering tulips, would make a continuously gay spring picture.

In autumn, the starry flowers of the Michaelmas daisy will be more emphatically incised when seen against the darker-leaved shrubs. EVELYN N. COWELL.

BORDER CAMPANULAS

BY GERTRUDE JEKYLL.

FEW FLOWERS HAVE A MORE DEFINITE PLACE AND CHARMING APPEARANCE IN THE BORDER THAN BELL FLOWERS. THOSE MENTIONED BELOW ARE SUITABLE EITHER AS A BACKGROUND OR AS AN EDGING.

THESE indispensable border plants may, for convenience, be put into two classes: namely, the taller kinds, suitable for the middle and back of the border, and the shorter, that will come well at the front edge. Of the taller bell flowers some of the finest and the earliest to bloom are the varieties of C. latifolia, especially C. l. macrantha and eriocarpa. The white form of C. macrantha is one of the very finest garden plants, with its stately spikes of large white bells and its good upright habit. It is of much use, not only in the flower border but in adjoining regions in part shade of shrubs or trees. We have it in such places grouped with the glossy fronds of Danæa Laurus, the Alexandrian laurel, and a further background of hardy ferns. It forms deep, thick roots that may remain several years in place, and is easily raised from seed. A fine plant of the same class came to me by seed from Switzerland under the name C. macrocarpa, possibly nearly identical with C. l. eriocarpa, for it has the large seed-pods that would justify the specific name, with the woolly covering characteristic of eriocarpa. The large flowers of this are drooping and of a reddish purple colour, and the whole plant more lax in habit than in C. l. macrantha. The next of importance for border use is C. persicifolia, in white and purple colourings. There are also double varieties, but the pure bell shape of the typical form is so good that doubling is hardly an improvement. The best of the double kinds is the one known as coronata—never a very frequent plant; it is not strictly double, but a hose-in-hose, with an outer range of petals as in the cup-and-saucer Canterbury bells. Rambling in mountainous woodland in Switzerland, at an altitude of about 1,500ft., I came upon a white form of C. persicifolia and collected a few roots. It responded well to garden culture, and after a few years of education settled into a fine form of this good plant. As with C. latifolia, it is charming in wood and shrubbery edges as well as in the flower border. It is one of the kinds that spread widely at the root. To have it at its best it should be divided as soon as may be after the bloom is over, and planted out in a cool reserve place. There is no need to cut the old flower stems; it is better to pull them out, when they bring away with them all the exhausted part of the plant, leaving an outer fringe of young growths that may be planted singly in reserve and will form good plants by the autumn. The same method applies to C. grandis, a useful border kind about 18ins. high, so often seen in gardens as a spreading clump with but few flowering stems, badly needing the same timely renewal.

C. ALLIARIÆFOLIA ADMIRABLE FOR THE EDGE OF WOODLAND.

C. LACTIFLORA ALBA HAS A NATURAL GRACE PARTICULARLY SUITABLE FOR THE SHRUBBERY.

C. lactiflora (celtidifolia) is a grand border plant much too often overlooked; unworthily so, as it is of prime importance. It rises to a height of 5ft. or more, and is in colourings pale lavender and from that approaching white; there is a deeper coloured form of shorter growth. It is easily grown from seed, but is not at its best till the second year after sowing. It is one of the plants that need careful staking, for the spreading heads of bloom, especially under the weight of heavy rain, can hardly hold themselves up, and may easily be broken down. But established plants are full of side growth, and a clever arrangement of branching spray can be introduced, so as to give the needed support without being obtrusive.

Digitized by Google

Of middle height, but anything up to 2ft., is the white-flowered C. alliariæfolia. It does well near the front of the border, where its quantities of drooping white bloom on side shoots, with a central taller spike, form a pyramid of flower with one higher middle spire. This is one of the bellflowers that is almost better suited to the wood edge. It is impatient of being transplanted, but comes well from self-sown seed.

The indispensable Canterbury bells are derived from a Southern European species, Campanula Medium; a rock-rooting plant in its native places. This suggests its use in our dry walls as well as in the usual places in the garden. The prettiest are the single and the calycanthema (cup-and-saucer) forms; the double, where the middle of the bell is tightly stuffed with shapelessly crumpled bloom, is much less desirable.

Of the lower-growing campanulas that are good for the front edges of the border, C. carpatica stands out as the foremost, both for good effect and for easy culture. It does well in either sun or shade. The height may be anything from 6ins. to 12ins. It comes easily by seed and varies in the shape of the flowers from the flattened forms of pelviformis to the deeper bells of turbinata. It has also been the parent of several useful garden hybrids. A campanula that is well suited to the front edge and has much merit, but is seldom seen in gardens, is C. sarmatica; it stands about 9ins. high and has greyish foliage and a quantity of pale lavender bloom. When the border has a raised edging of rough stones some of the smaller bellflowers can be used, such as the bright purple Portenschlagiana and the delicious pale lavender garganica, also the small pusilla and its varieties; but without the prominence and protection of such an edging they would be lost.

It is well to remember that nearly all the campanulas are plants of the limestone, and that therefore they will do all the better if they are given lime in some form. In making up a stretch of dry walling where it is intended to grow them, if the soil is not naturally calcareous, the joints should be prepared with old mortar rubbish or any form of lime as sold for garden use. When this is done even the tender South Italian C. fragilis and its near relatives Barrelieri and isophylla may be grown successfully, the crowns being protected by the stones from excess of winter wet and the roots revelling in the limy food. All that delightful series of tiny bellflowers, pulla, pusilla, and their garden hybrids, may also best be grown in lime in the wall.

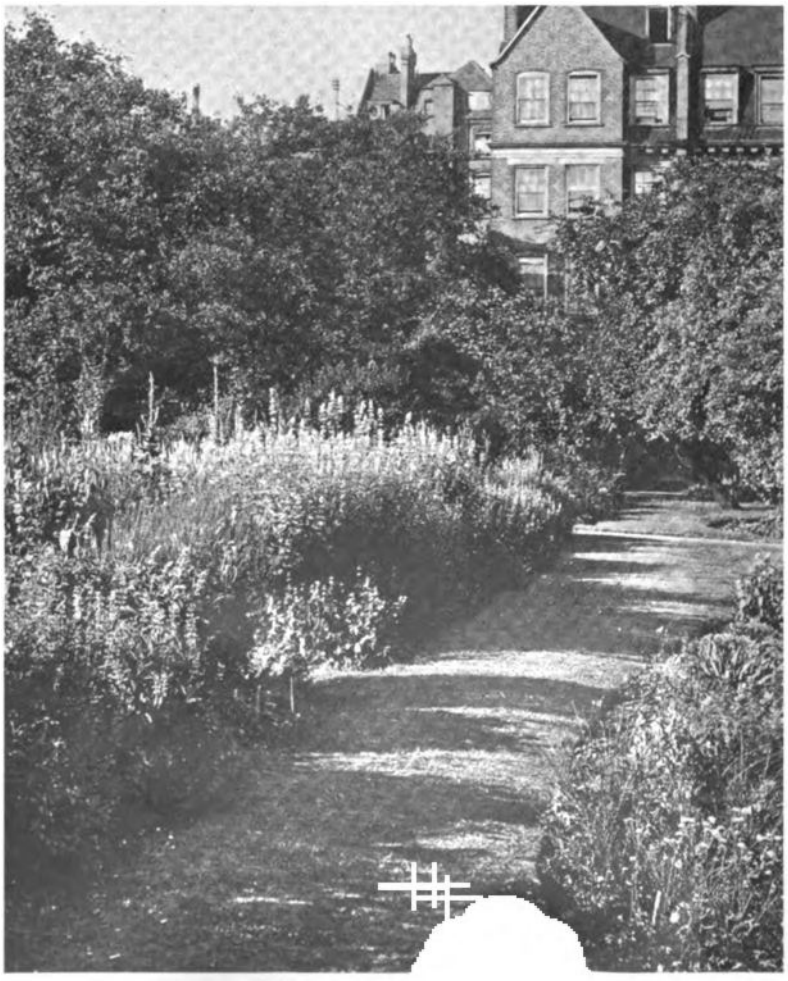
LONDON'S OLDEST BOTANIC GARDEN

AFTER TWO HUNDRED AND FIFTY-ONE YEARS THE CHELSEA PHYSIC GARDEN IS IN AS FLOURISHING A CONDITION AS IT EVER WAS, LARGELY OWING TO THE DEVOTION AND SKILL OF THE PRESENT CURATOR, MR. HALES.

IT is sufficiently surprising that a botanic garden exists within two miles of Charing Cross, but my wonder grew and my eyes opened wide at the extraordinary growth and vigour shown by those plants growing in the middle of London. It is as well, however, to point out that the Chelsea Physic Garden is not and never has been a garden for show purposes and it is not open to the public, except by ticket. It is strictly utilitarian in its purpose and is kept for the use of students and experimenters attached to the London University and colleges. All the same, as the accompanying illustrations show, it has a charm and romance about it which are probably unequalled in any other garden in the middle of a big city. It accomplishes its work in such peace and solitude that few people in London and fewer in the country know of its existence.

A great deal of its romance is caused by its famous associations, for it played its part in late seventeenth and eighteenth century botany, probably more than any other institution. It was founded in 1670 or in 1673. Mr. Hales believes in the earlier date—by the Apothecaries Company, which apparently also had a garden previous to that date, on land which belonged to Lord Cheyne. The first few "demonstrators of plants" were practising apothecaries who, although interested in the work of growing and teaching about plants to be found in the pharmacopœia, were obviously unskilled in their actual cultivation and the garden fell upon days, so bad, that the whole scheme was nearly dropped in the first few years after its inception. It was saved by the appearance on the scene of Sir Hans Sloane, who purchased the Manor of Chelsea from Lord Cheyne in 1712 and transferred the freehold to the Apothecaries Company in 1718. Among some conditions which Sir Hans Sloane made was one stipulating that the garden was to supply fifty plants a year to the Royal Society, until a total of 2,000 had been given; actually this number was exceeded, for until the time when the gift was stopped, about 1770, the garden had supplied over 2,500 plants.

From the time of Sir Hans Sloane's purchase for more than a hundred years the garden was in a flourishing state; not only were plants introduced from abroad, but herborisings were made under the



A PEACEFUL GARDEN IN LONDON

Digitized by Google

directorship of the Demonstrator of Plants in the home counties, by means of which much of the local flora was introduced to the garden. They must have been curious entertainments, for each day ended with a dinner of the usual magnitude of the time. But it is the names of the eminent scientists or gardeners who either worked in the garden or were taught there which is a real link with the past. One of the most famous was Philip Miller, the author of the "Dictionary of Gardening," who was actually in charge of the garden for forty-eight years. Linnæus visited him there in 1736, while Sir Joseph Banks and Dr. Solander received part of their early training from him. Other famous demonstrators were William Hudson, William Curtis, the founder of the *Botanical Magazine*, Robert Fortune, John Lindley and Thomas Moore.

Towards the end of last century the garden again fell on evil days, until in 1899 it was transferred from the Apothecaries Company to the City Parochial Foundation, who now keep it up under Mr. Hales' able management for the use of the University and Colleges of London.

As I pointed out before it is strictly utilitarian in its purpose. In the glass-houses are collections of weird and interesting plants, sensitive plants, insectivorous plants, plants whose leaves are not leaves but stems, and plants whose stems are not stems but leaves; cotton is also being tested and boll weevils hatched out. Out in the open are beds devoted to the different natural orders. Here also much experimental work is being done: beds are devoted to testing leaf curl in potatoes and the value of different manures; while on the occasion of my visit a professor from overseas was busily engaged in inoculating different grasses with some bacteria for some purpose unknown and indescribable.

But apart from the scientific side there is much that is charming in the garden. There is an old catalpa on the lawn in front of the house, which has grown as if it were a hundred miles away from the smoke and dirt of London. There are masses of old English plants rarely seen in gardens, among them I noticed a magnificent collection of different mints. Was there ever a finer clump of Iris Neptune than is shown in the illustration?

And then in the middle of the garden is a fine statue of Sir Hans Sloane; on the side is to be found the following: "They being sensible know how necessary that branch of science is to the faithful discharging the duty of their profession. With grateful hearts and general consent ordered this statue to be erected in the year of our Lord 1733, that their successors and posterity may never forget their common benefactor." He now looks serenely over what must be one of the most peaceful spots in London.

SOME RECENT DEVELOPMENTS OF THE BEARDED IRIS

BY SIR ARTHUR HORT, BT.

MOST people, when they say "irises," mean tall bearded irises, what used (absurdly enough) to be called "German irises." In this article we shall have quite enough to occupy our space if we try to cover a part only even of that limited field. I wish to try to show how, by the introduction of new wild forms and by hybridising, the standard of irises worth growing has been recently raised. Anyone who has seen the exhibits of irises of this section at Chelsea or Vincent Square in the last few years is aware that the standard has risen amazingly, and that now there is a bewildering choice of an enormous number of fine plants, raised in England, France, America and Germany. This remarkable development, which has made the iris, once a curiously neglected flower, almost a craze with up-to-date gardeners, has proceeded along various lines. Of these I can only indicate a few which happen to have come under my own observation.

Some thirty years ago English gardens could show a certain number of more or less handsome bearded irises, which, being vaguely supposed to be varieties of Iris germanica—the early purple flag so familiar alike in cottage borders and in London squares—were called "German irises." Indeed, I have heard people complain that their irises, in time, all "went back" to "the old blue"; the explanation being, no doubt, that the latter aggressive plant had increased at the expense of the others. Such "reversion," needless to say, is impossible, except in the case of seedlings, and I. germanica typica (so-called), very rarely sets seed. Now this raises the curious problem of the origin of that famous and popular plant, whose name implies that other forms of germanica are varieties of it, and which was once supposed to be also the origin of the crowd of other tall bearded forms loosely lumped together as "German irises." As a matter of fact there are many forms of I. germanica, and it is probably merely by accident that the blue-purple form, with which we are all familiar, has been made the "type." This form is not often seen in France, where, especially in the South, other forms are exceedingly common, at railway stations, on the walls of cottage gardens, and about old castles. But the remarkable thing is that no one has ever seen I. germanica (I am speaking of the West European form) where it was undoubtedly wild; or, if anyone has done so, he has kept the observation to himself. This statement is, perhaps, just a little too sweeping, since Mr. Dykes, a very careful observer, mentions in his new "Handbook of Garden Irises," that he found the form called Kochii above Lake Como, "in a position in which it seemed that it must be wild and not merely an escape from cultivation." The numerous forms may be divided into three classes, red-purples, blue-purples, and whites; the best known of the whites has long been called I. florentina, being the plant supposed to be cultivated near Florence for the orris root, used as a perfume and drug; though, as a matter of fact, when Sir Michael Foster asked someone in Florence to send him rhizomes of the economic plant, he received four or five different things (including pallida), but no florentina! Of the blue-purple forms the best known is Fontarabie (also called asiatica in the trade), which I have seen covering the limestone cliffs of the Rocamadour in the South of France. Of the red-purples some forms come near the Oriental Kharput, and a very common dwarfer plant is australis. The darkest and perhaps the handsomest is that known in England as atropurpurea or Purple King. A rampant grower, which requires frequent division to make it flower freely. (Along with these West European forms may be mentioned an even darker Eastern form called Cretan, with nearly black falls, introduced by Mr. Dykes from Crete; this is a superb variety and, being very free-flowering, will perhaps eventually supplant Purple King in our gardens). I have already mentioned Kochii, which is very near Purple King.

Now the problem is this: seeing that this plant, in a variety of forms, is exceedingly common, but only seems to occur near where man lives or has lived, where did it (or rather *they*), come from? One may guess that it was first introduced to Western Europe as an "economic" plant, that is, to produce orris root. But who first planted it centuries ago, even in remote villages of the lower Pyrenees? Whence did he bring it? Why does it present such a variety of forms? Some day the solution may be found by raising plants from seed, but there is this difficulty, that these western germanicas rarely produce any fertile seed.

(To be continued.)

WATERING

UNDOUBTEDLY the most satisfactory way of watering is by the use of the hose pipe, and if one has a hose pipe long enough to reach all parts of the garden one is in a very happy position. Local application by means of a can is a very unsatisfactory way of watering, since it is difficult to get the spray fine enough, and at the same time to be sure that the water is economically used. If, however, the hose is handled properly, and held so that the water shoots up into the air instead of directly on to the plants, a fine mist-like spray which wets every portion of the plant as well as the soil and surrounds the plant with a cool humid atmosphere for several minutes after the water has fallen, is the result. Such an atmosphere is exceedingly refreshing to flowers and vegetables during the hot months of the year, and it is as near to an actual summer shower as we poor gardeners can get. The spray from an ordinary rosed can resembles the torrential rain of a thunderstorm, and may do quite as much damage as it does good.

The importance of a really long hose cannot be too strongly insisted upon. How often does it happen that when the outlay has been made on a pipe it is found that it is 50ft. or 60ft. too short to reach the extremities of the garden! We frequently find, too, that just those very crops, such as saladings, which require gallons of water to produce juicy leafage, cannot be dealt with by the hose, however well directed the nozzle of the pipe may be. A hose is intended to save many hours of labour, but one that is too short is more trouble than it is worth. Hence all gardeners who are considering the purchase of a hose out of their employers' purses should take the trouble to measure up the ground in every direction before they state the number of feet or yards required, and be well on the right side of the length of pipe required.

In making this purchase more often than not a single nozzle is supplied. A hose pipe, however, with only one nozzle is about as useless as a teapot without a spout or a badly broken one. A variety of nozzles and one or two rose-nozzles should be taken to complete the outfit. When using a hose for watering it does not matter if the rose is rather a coarse one in the first instance, as, if the pipe is held upwards instead of downwards on to the plants, the water disseminates into the air finely in any case. If, however, a fine rose is obtained as well as a coarse one, the usefulness of the pipe will be doubled, since it can then be used for almost any variety of flowers or vegetables, including the tiniest seedlings.

A hose-reel should also be included in the outfit. Reels are often on the small side, so the purchaser should see that he gets one large enough to take the entire length of the hose pipe. One may have to be specially made for extra long lengths of piping in big gardens. When the reel is too small the pipe invariably gets round between the wheels and ties itself up into knots in a most objectionable manner. If a reel is not purchased, and the hose is dragged roughly along hard asphalt paths, it

Digitized by Google

naturally wears rapidly into holes and begins to leak, and portions of it have to be renewed within a few months of purchasing it.

Just a word now about the use of the watering can, as there will doubtless be many gardeners who will not be able to obtain a hose pipe on account of the expense being prohibitive. The watering can should be as large as the gardener is able conveniently to carry short distances when full of water. It is difficult to recommend any particular size, as gardeners may have Herculean strength or they may not. A can to hold four gallons (a favourite size) is somewhat large for most ordinary purposes, and one certainly feels the weight of such a can after carrying it up any steep garden paths one may have. Small cans holding about a gallon or half as much again are splendid in use, and not tiring for anyone. Lady gardeners are recommended to what is known as the "lady's watering can" for odd jobs and small borders, as this is very handy and useful.

Speaking of watering cans reminds me of roses again. There is a rose that I like, but, unfortunately, I am unable to remember its exact name, and cannot find it in lists before me. It is of the mist-spray type—a rose that is put on the watering can with its holes upwards, and when the can is tipped the water shoots out in an upright direction before turning back to fall on the plants. This spray of water is often 12ins. to 18ins. across, and thus a very large area can be covered in a short time. While buying roses, however, for one's watering can, see to it that a very fine one is obtained, otherwise much damage may be done to seedlings which have been recently pricked out by a heavy weight of water falling upon them.

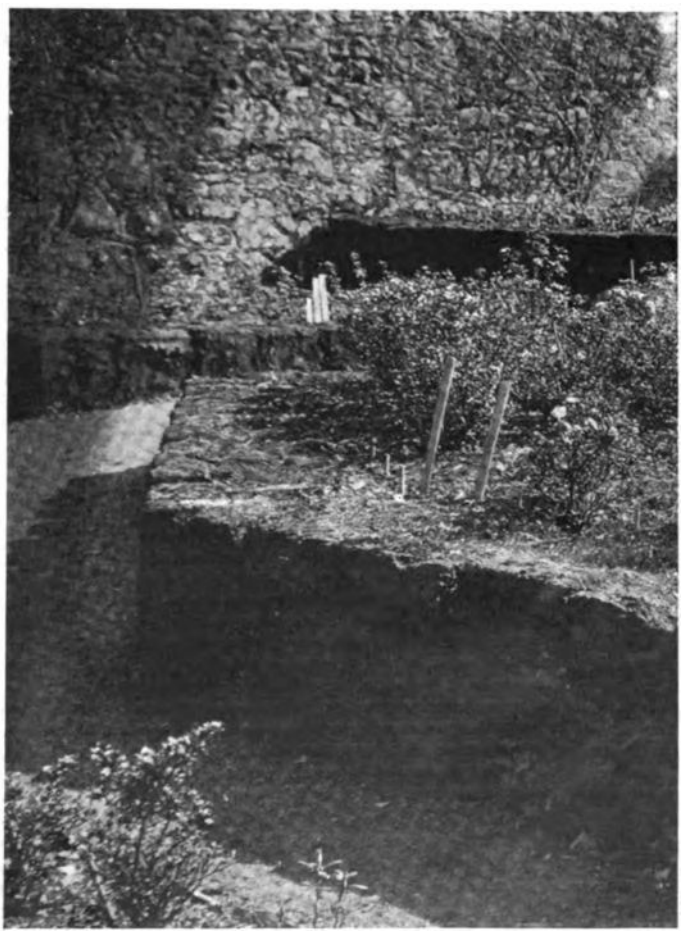
And now about the actual application of the water. It must be confessed that it is very unlikely that one will overdo it. Many gardeners, however, imagine that if they just damp the surface soil and the leafage of flowers and vegetables, they have done a good day's work, and that this watering will not need repeating for a considerable time. Watering of that sort, however, is practically useless. It freshens up the foliage, it is true, but it attracts the roots of the plants to the surface, when one wants them to be down below out of harm's way. Thus, if water is scarce, it would be well to apply it thoroughly to one set of plants and leave the others to go without, instead of supplying a little to all and running the danger of surface rooting and consequent injury. The golden rule, I consider, in watering is to be thorough. Mulches will do much to conserve the moisture if applied immediately after the water is given.

Now, as to the best time to apply water. Obviously no gardener who loves his plants would apply water during the hottest sunshine of a June, July or August day; but there is great diversity of opinion as to whether it is better to apply water in the early morning or in the evening. A theory has been launched that if it is applied in the early morning the plants are able to suck it up, and to benefit materially by having it close at hand during the hot sunshine of the day that is before them. More often, however, it has been shown, if plants are watered thoroughly in the early morning and this water falls, as it should, on their foliage as well as on the soil, that considerable leaf scorching results, owing to the sun magnifying the drops of water on the leaf surfaces. Undoubtedly, too, a great deal of water on the surface-soil rapidly evaporates, and thus is wasted so far as the plants are concerned. Personally, I always urge those who possibly can to water their plants after five or six o'clock in the afternoon, the later the better. Then and only then can one retire to rest feeling that one has done a really satisfactory day's work, in which there has been no waste either of time or of valuable water. E. T. ELLIS.

PEAT TERRACES

AT Logan, near Stranraer, Mr. Kenneth McDouall has started an innovation which should become popular in many gardens, particularly those which are in a peaty district. Unfortunately, this is a difficult subject to photograph, but a general idea of his use of peat can be seen from the accompanying illustration. The walls are made out of blocks of cut hard peat, while the insides of the terraces are filled with worked peat. These walls are easy to make, but should not be quite perpendicular. As Galloway is a wet district and as these terraces have been in use for some years, it appears that they will last a long time and are not affected by inclement weather.

These peat walls have three advantages: they are cheap to construct, they are easy to repair, and they do not hold in the rain, so that perfect drainage is effected, which is so necessary for most peat-loving plants. These particular terraces average about 18ins. in height, but there is little doubt that the walls could be made even higher. At Logan the terraces are filled with alpine rhododendrons, lilies and nomocharis. They are all completely at home, while the nomocharis, usually so difficult to cultivate, actually runs through the beds.



A TERRACE MADE WITH PEAT WALLS.

There seems to be little objection to using good strong turf for the same purpose, although we have not heard of this use being made of it in semi-permanent positions. We should be glad to hear from any of our readers who may have made the experiment and found it successful. There seems to be little reason why this class of semi-permanent terracing should not become popular. It is easy to make, at little cost, and as easy to remove; therefore, it might be useful for improving ungainly or unwieldy slopes; on the other hand it would be impossible to use it on anything which approaches the precipitous.

CORRESPONDENCE

THE PURPOSE OF WISLEY.

SIR,—With reference to the Editorial article on the purpose of Wisley in THE GARDEN of June 28th, I think the Editor has raised a few very interesting points and some, if not all, will be the views of a good many of the Fellows of the Royal Horticultural Society. Paragraph 1.—Undoubtedly this should be carried out to the utmost. Paragraph 2.—The remarks on the trials of vegetables are, in my humble opinion, very much to the point, and reference to the Book of Arrangements will show what vegetable trials are due. These vegetable trials are only of interest to a very small portion of the Fellows, the public and the trade. Trials of flowers, on the other hand, would interest a much larger portion of the gardening public. From the trade point of view I think much more could be done in this direction of trying to obtain true nomenclature in shrubs and plants that are now in some confusion. The trials could be carried out with a view to discarding inferior sorts and settling *the* name of a plant where it has two, three and sometimes four names—all synonymous. I think the trade would benefit by seeing what to grow, and what to call it, and so avoid growing inferior sorts and getting hold of wrong names. Paragraph 3 would represent a sort of permanent trial, but new sorts should be added as soon as possible to enable people to keep up to date. Paragraph 4.—I hesitate over this so long that I pass to paragraph 5. If Wisley is to be a sort of distributing centre for new plants that cannot be bought in nurseries it would not be long before they could be bought in many nurseries, as trade Fellows of the R.H.S. would be able to obtain plants and work up stocks. This would probably be appreciated by some of the trade, as there are difficulties in getting plants, etc., from the Royal Botanic Gardens at Kew, Edinburgh, Glasnevin, etc. The R.H.S. do so much for the gardening public that one does not like to be trying to find fault, but in all humility I feel the Editor has done a great deal of good in his criticism, and I hope others will give their views in an equally well meant criticism.—G. H. DALRYMPLE.

VEGETABLE RECIPES FROM ROME.

SIR,—May a very ignorant flower lover add her praise of THE GARDEN? I feel I have learnt most of what I know from its pages, all kinds of information from roses and irises to the *taille lorette* for fruit trees. Of course, much of it is over my head and beyond any possible chance of experience here, but there is always something interesting and useful.

The new departure (cooking) is especially good: of what use are fine vegetables unless they can be well served and in sufficient variety? A vegetable may be dull in one dish and enticing in another. Is anything more washed-out than boiled vegetable marrow? However, that same marrow, cut in long slices 3ins. or 4ins. long, either very fine or thick as a little finger, rolled in a beaten egg, *lightly* dusted with flour, and fried in *hot* fat, is as highly flavoured a dish as one can want. The small green marrows (the Italian "zucchine") are best, but even winter pumpkins or Hubbard squash are not bad this way. Marrows may be cut in thin round slices, dusted with flour and *sauté* in butter, and are very good.

Eggplant may be *sauté* in butter and is a delicious garnish to boiled beef, or served as an extra vegetable. The slices should be first sprinkled with salt, and a plate a weight put on top of them for two this draws out the acid juice and lea tender and mild.

A famous Italian dish is eggplant "alla Siciliana." One takes *sauté* slices of eggplant and places them in a deep dish, alternating with thick slices of raw tomato until the dish is full. A brown sauce—made of a brown roux and either hot water or stock—is poured over, and the dish is put in the oven until the tomatoes are cooked, perhaps half an hour, perhaps more. Even the parsnip so disliked by the Editor can be served in various ways; cut in dice with a cream sauce, boiled, cut in long slices the entire width of the parsnip, and then *sauté* in hot butter, or mashed like potato cakes.

I do not know whether okra will grow in England; it makes several very fine soups, and also is cooked with chicken, rice and tomato, like a pilaff, and its distinctive flavour is very good.

Sweet corn, scraped from the cob and mixed with melted butter, a beaten egg and a little flour, and cooked as a soufflé, is delicious.

During the war, when sometimes we went for weeks without meat, we often made a large timbale of boiled rice, of which the centre was a macedoine of whatever cooked vegetables we could find—peas, carrots, celery, asparagus tips, etc. The timbale was browned outside and was a meal in itself, with or without a sauce.

In this country, with the young lamb chops a purée of marrons (chestnuts) is often served instead of potatoes, but it should always be accompanied by spinach or a green vegetable.

This is only a hasty note, as I am away from home and cook and cook-books, but it may suggest to others to try these things.—A ROMAN READER.

FRAGRANCE IN THE GARDEN.

SIR,—A popular daily paper has commented upon the fact that some of our best known flowers are losing their fragrance, and mentions roses and musk in particular. In the case of roses, it is not so much a loss of perfume in varieties known to have possessed sweetness, as it is the introduction within the last two or three decades of sorts whose charm lies solely in the beauty of their petals alone. Standing before a bed of Frau Karl Druschki with a friend last summer, he remarked on the purity of the blossoms, and added, if it only had the fragrance of Grüss an Teplitz, Hugh Dickson, or old Madame Abel Chatenay, it would have no equal among white roses. Perfume is a wonderful attribute in any flower, but in the queen of flowers it means so much. In some of the old sorts we have a splendid legacy by "the very sweetness of their breath," and modern raisers, despite criticism are fully alive to the importance of giving us varieties that are rich in perfume. It is a fact that the old garden musk, so prodigal with its small yellow flowers, and once so highly fragrant, has lost its virtue in this respect, in many places at all events. In a garden the other day I saw a large patch, utterly devoid of any scent, although the owner told me that up to ten years ago it was quite sweet. I have wondered since whether it was owing to it having been left undisturbed that had anything to do with lack of perfume! From enquiries made I have come to the conclusion that this once old garden plant has lost its chief charm. But we have many things in a garden upon which we can rely in the matter of sweet scent. The lilac has yet—

> 'A load of balm
> For every wind that stirs.'

Sprays of white jasmine at nightfall—

> "Let their delicious secret out,'

ugh they—

> 'Keep their odour to themselves all day."

this is equally true in respect of the blossoms of that simple and somewhat insignificant annual, Matthiola bicornis.

Now and again one hears complaints of sweet peas introduced within the past few years as having little scent compared with those of twenty years ago. Personally, I think we have little to grumble about in this, one of the most beautiful and prolific of our annuals. What I venture to say is lacking in most modern gardens are the shrubs and plants that contribute fragrance through their leaves as well as flowers. Some of them are regarded as out of date. Instances of lavender and rosemary and sweet briar bushes occur to us. We have had these many years and they have been left in possession of their original quarters. Many a time we have been tempted to move them, but as we press the leaves between our fingers, or go into the garden after a shower of rain and the air is scented with them, our intentions vanish! I pen these notes on a night in June near an open window. Has anyone need to tell me that within a few yards there is a border filled with pinks? Not the slightest, as the fragrance of that sweet sort, Mrs. Sinkins, pervades the house!—CLAREMONT.

GLADIOLUS BYZANTINUS.

SIR,—I am writing to ask if the attention of the experts has ever been directed towards improving the common early Gladiolus byzantinus? It seems such a pity that a plant of such strong constitution, early blooming quality and graceful long-stemmed habit should remain such a "difficult," not to say ugly, colour.

It comes at a time when cut flowers are none too plentiful. Here it usually flowers in mid-May—this year, of course, much later. It fills the gap between the tulips and the early summer flowers, and blooms from seed within the year. In my garden it has always existed, never *cultivated*, our efforts being chiefly directed to reducing its exuberance. It comes up everywhere on its own. This year a group appeared among the bearded irises and it chose Mme. Paquitte as its neighbour with charming results as to colour harmony. Away from strong yellows, reds and blues, it is by no means to be despised. I placed some in a tall vase with sprays of pale salmon clarkia; the effect was quite delightful. But, of course, it remains, as I said, a difficult colour, and it seems to me that it should be easy to improve it, while retaining the early-flowering habit and strong growth, so superior to Colvillei. Here the latter never does well out of doors, though all the other sorts of gladioli flourish exceedingly.—SYLVIA M. PRENDERGAST, *Isle of Wight*.

ABOUT FIGS.

SIR,—I take THE GARDEN in regularly and send it on to my sister in San Deigo, California. A few weeks ago I read in one of the articles that figs do not grow from seed in England. I have two seedling trees about six years old. They came up through a hole in the side of a frame (we had at that time been having figs sent from Worthing). The young fig trees have had no fruit on, the leaves are unusually large and are brownish red before they unfold. The trees are about 5ft. high, perhaps more. I am most interested in all flowers that have a scent, and have gardened since I could walk. This house dates from the twelfth century, but the only garden thing that looks old (except two clipped yews) is a bush rose that grows out from under the house. It is an intense pink and semi-double. I have an air plant which I brought from Argentina, but it is not flowering this year.—ALICE M. ROBINSON, *near Chichester*.

NOTES FROM CONTRIBUTORS

JUNE FLOWERS.

ON looking over the garden during June, when multitudes of flowers are to be seen on every hand, one is led by some outstanding feature, such as colour, wealth or magnificence of bloom, to memorise and, if need be, add such to perhaps an already long list of garden favourites. With the Editor's permission I would like to name a few. Though not by any means new, some are not too frequently met with. Commencing with the alpine garden, Achillea conjungta is one of the best white flowers in the garden, flowering throughout June. Æthionema stylosum is, to my mind, the best of the genus we have, but, unfortunately, not so hardy as some of the others, though it has come through, without injury, the winter of 1923–24, when we had but nineteen days out of five months without frost. However, it is well worth a little trouble in keeping a stock in hand, for A. stylosum has flowers of beautiful soft pink and these are produced in great profusion; the whole plant flops about in a delightful manner. Saxifraga Dr. Ramsey is a favourite that yearly adds more praise to its credit, owing to its free-flowering character, largeness and great beauty of its flowers and silvery foliage. Calceolaria John Innes is a giant beside the well known C. polyrrhiza; the flowers are yellow with mahogany spots and are fully 1½ins. long and 1in. wide. Like all the above-mentioned plants, it enjoys a warm, well drained spot. Mimulus Whitecroft Scarlet is a beautiful little plant about 3ins. or 4ins. high, suitable for a half-shady position.

In the shrub borders Meconopsis latifolia is by far the finest of its class. It has flowers of a beautiful pale azure with golden anthers. Here, by accident, it was planted through a drift of Tulip Noire and it seemed a desirable contrast. Near by a group of Lilium rubellum, a Japanese species with rose-pink flowers, goes on increasing yearly. Along a south wall old favourites such as Abutilon vitifolium album and Ceanothus floribundus would, if it were possible, endear themselves afresh, so dense has been the ceanothus and magnificent the abutilon. Here, too, the strong-scented Lilium monadelphum Szovitzianum has reached nearly 5ft. in height.

Veronica Hulkeana, though killed outright on this wall, flowered splendidly in another part of the garden. In a garden principally devoted to irises the pretty Ixiolirion Pallasii has been much admired. This plant seems to like its light soil and warm spot.—J. T. H., *Dupplin Castle Gardens.*

THE LIZARD ORCHIS (O. HIRCINA).

THE photograph was taken in dull weather on June 28th near the coast of the Bristol Channel, where last summer a remarkable colony of this orchis, so rare in England, was discovered. But a careful examination of its environment a month ago soon confirmed one's supposition that it is a relic of cultivation—probably introduced years ago from seed from the Continent, where it is so plentiful and widely spread. Nevertheless, it was a very interesting find by the lady who made it, and a noteworthy occurrence when we remember the difficulty usually experienced in cultivating our native orchids. On June 8th I counted no less than eighty-four plants, including some without spikes and a few damaged ones; but the site is so exposed to the view of passers-by, and the plant so peculiar when later in flower, that it was not surprising to find the number appreciably diminished by June 28th, though even then many of the spikes were not yet in blossom.

O. hircina is remarkable for its very long linear and twisted central lobe, and it is

A RARE BRITISH ORCHID, O. HIRCINA.

the largest European orchid. Often 2ft. to 3ft. high, it is closely followed in height by the strange parasitical limodorum, and the handsome Orchis longibracteata, which opens its flowers in February on the Mediterranean coasts, together with an epipactis or two, often tie for a poor third in the race.—H. S. THOMPSON.

PEARS ON A COTTAGE WALL.

THE accompanying illustration shows a Beurre Clairgeau pear tree. As the name indicates, it is a most delicious variety,

A HEAVY CROP OF PEAR CLAIRGEAU.

which positively melts in the mouth like butter.

It grows on the sunny front wall of a little cottage in a West Country village. The fruit this year is so plentiful that in order to keep it from weighing down and breaking the boughs of the tree from the wall, an old fishing net is requisitioned, which both supports and protects the fruit until it is ripe for gathering.—L. E. K.

TULIP BOUTON D'OR.

BOUTON D'OR is a fine old May-flowering tulip, but it is one which varies very much in size according to the ground in which it is grown. No one who is unprepared to see this difference would recognise the mammoth flowers which Messrs. Dobbie and Co. have staged at Chelsea in past years as being the same variety as the much smaller ones which have come from rather a poor soil. The black anthers, or rather pollen grains, are an unfailing mark. I write this note not only to call attention to an old favourite, but to make known a bedding combination which has been suggested to me by the Hobson's choice of suitable flowers for our Communion table last Whitsuntide. The best one could do was a mixture of Bouton d'Or, which, being in a sheltered place, had escaped the worst effects of the deluge of the previous week, with a ground of the orange Erysimum Perofskianum or Caucasian wallflower, set off with the fresh young shoots of Alstrœmeria aurantiaca. —JOSEPH JACOB.

THE HYBRIDISATION OF THE ROSE.

ROSE hybridising has a charm all its own, which is never lost when once it has been felt. You can grow and propagate roses which you alone have produced, and behind all there lurks the secret ambition to produce one which all shall acclaim.

The method of procedure is simple. Choose any good rose—thin varieties should be chosen at first, such as K. of K., Mermaid, Irish Fireflame, etc., until sufficient skill in manipulation has been obtained. Take a young bud, just showing signs of opening, pull back the covering green sepals and gradually peel off the petals one by one. Then, with a pair of small scissors with sharp-pointed blades, carefully remove every stamen. If any remain they will pollinate the pistil and nullify the cross, as the pollen belonging to a rose appears to be stronger than that of another variety. If any pollen can be perceived with the aid of a small lens, the flower must be cut off and another prepared. After this operation has been successfully performed, a small piece of grease-proof paper should be wrapped over the flower and left for one or two days for the pistil to mature.

When the pistil is mature, take some pollen from an open bloom of some other rose by means of a camel-hair brush inserted into the centre of the bloom and moved gently around. Then if there is a distinct dusting of pollen on the brush, remove the wax paper and stroke the pistil with it. Cover the hip again and leave for a week or so.

When ripe, the hips should be stored in damp sand until January, when the seeds should be separated and sown in sandy soil. Place outside till March and then remove to a gentle bottom heat.

The same brush should not be used for different varieties of pollen without sterilising. The choice of varieties for crossing is a complex subject, but some attempt should be made to combine opposites to form the ideal—by crossing, say, a very full rose with a thin scented variety.—F. R. TUBBS.

WASPS AND THE FRUIT CROPS.

SUDDENLY, when the first mild spell of weather came in the spring, queen wasps appeared to be very numerous. Judging from this fact one may reasonably expect a plague of wasps during the late summer and early autumn months. The queen wasps for next year will be hatched during the last six weeks of the nesting season this year, and the majority of these nests will be found near to water—chiefly running streams. Of course, we should net choice fruits and also place nets over the ventilators of vineries where good bunches are ripening; I do not believe in the method of placing nets on individual bunches. I have found it answer well to saturate flannel rags in petrol and suspend a few pieces from the wires in the vinery. The wasps leave the structure. Renewal is necessary twice a week owing to evaporation. Trace wasps from the garden to their nests, mark the latter with white paper tied to sticks. At sunset insert into each entrance hole a small roll of cotton about the size of one's finger, after saturating it in turpentine. Place a spadeful of earth on the hole, trample it firmly, and all the wasps will die.

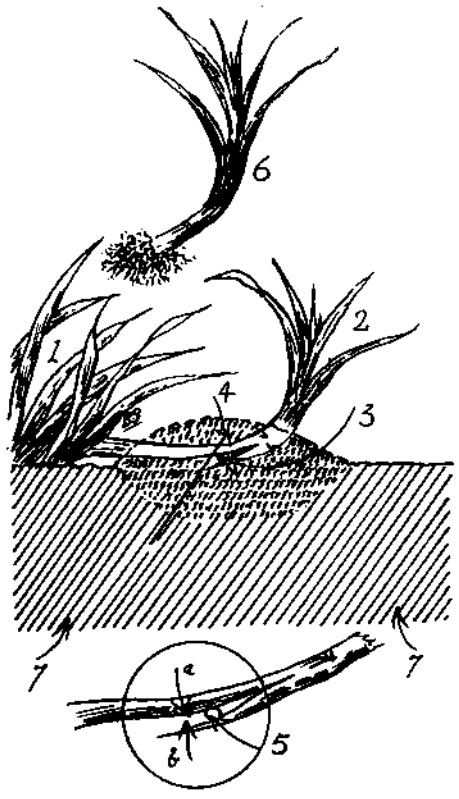
ANTIRRHINUMS FOR SPRING FLOWERING.

The popularity of snapdragons increases every year and, I may add, their general usefulness, too. If seeds are sown in the open border—a nursery bed, of course — and the resultant seedlings duly transplanted into their permanent quarters, an early display of blossom will result in the garden. But we are rarely satisfied to wait for such displays, we like to have flowers just a few weeks earlier and so make provision accordingly. For this purpose, seeds of the variety Nelrose should be sown thinly in a box towards the end of July. Although antirrhinums will grow well in a poor soil in the garden, they are nearly failures so grown in pots and boxes unless well fed. I recommend a moderately rich, fine soil for raising the seedlings in and a similar one for the first transplanting of them. This planting should be done at 2ins. apart, either in boxes or in a well prepared bed.

Boxes about 1ft. long and 9ins. wide and 7ins. deep are ideal for containing fifteen plants. Nine inch flowerpots will contain nine plants. The boxes and pots should be drained with lumpy turf, rotted manure and half-decayed tree leaves. The general compost should be a rich one, fibrous loam one-third, rotted manure one-third, leaf-soil and old mortar rubble one-third. The compost should be of medium firmness when the seedlings are planted and both pots and boxes kept on a bed of ashes in the open air until the end of October, then in a cool frame, being transferred from the latter to the greenhouse at the end of December.

LAYERING BORDER CARNATIONS.

To be quite successful in carrying out this operation, the cultivator should provide a sufficient quantity of gritty compost to allow, at least, a 6in. potful of it to each shoot to be layered. A very sharp knife is also essential and the careful clearing away of all dead "grass" around the base of the old parent plant. Now, we may begin the actual work of layering; the accompanying sketches show how it



should be done. No. 1 the parent plant, No. 2 the side shoot or branch to be layered, No. 3 shows how the cleaned stem is neatly slit in an upright direction and a tiny pebble placed in to keep the lip open. No. 4 shows how to insert the peg, which is to retain the stem in one position. No. 5 shows the circle within which the prepared compost is placed and new roots formed, mainly from the insides of the lip and stem *a* and *b*. No. 6 shows the rooted layer severed from the old plant, and Nos. 7, 7, the ordinary border soil. The new compost should be kept well watered in dry weather.

VIOLAS AND PANSIES FOR SPRING FLOWERING

The cultivator will not find much difficulty in securing a display of flowers from these plants during the greater part of the year if he decides to sow seeds twice a year—in July and in early spring. I am leaving out of this note any reference to the raising of violas from cuttings. From good strains of seeds I have had a great measure of success as regards form and trueness to variety; a few rogues are sometimes found and thrown out. Autumn planting is to be recommended, especially in Southern England, as then the plants do not suffer checks as those do that are planted in spring. In Scotland we know that both violas and pansies are safe in the care of the enthusiasts residing there. In northern counties of England mid-July will not be too soon to sow seeds, whereas, in southern counties the end of the month or first fortnight in August will be soon enough. The seeds should be sown thinly in very shallow drills and in a naturally cool border, but not one situated under trees or in the shadow of high buildings. These tiny drills should be flat at the bottom and the seed covered with some finely-sifted soil. In a very short time the seedlings will appear and care should be taken to protect them from slugs. In the case of choice varieties it may be advisable to winter the young plants in cool frames whether permanent or temporary. In the meantime the cultivator should prepare the soil in the flowering quarters by deeply digging it and putting in a liberal supply of well rotted manure. About one month prior to the final planting scatter one peck of soot on the surface at the rate of this quantity to 10 sq. yds.

CELERY AND THE CELERY FLY.

This plant is spoiled if it is coddled in its early stages of growth—by being subjected to too much bottom heat or even a high temperature in the structure. Then there are those plants—numerous enough this year—that are, as regards soils and manures, well treated, but being spoiled by the leaf maggot. The mischief occurred in spring when the fly deposited its eggs in the leaves, the harvest of resultant grubs coming in June and early July. Hand picking and crushing only could be done. Now, the fly is busy again depositing eggs, the grubs will come in late August and September. Prevent the fly depositing eggs by sprinkling wood ashes and old soot on the leaves and freely on the soil twice a week. Quassia water syringed on the leaves will also answer. The present is a good time at which to begin feeding celery judiciously.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Early Potatoes.—These may be lifted and stored in a dark, cool shed; then the ground will be available for other crops. Collect the haulms and lightly fork over the ground, then it will be ready for lettuces, radishes, spinach, turnips, globe beet, carrots and early dwarf peas.

Herbs.—These should be gathered as they come into flower and dried in an airy shed. A fine day should be chosen.

Dwarf Beans.—Early frosts often destroy the crop of dwarf and runner beans, so to make sure of a late supply in the autumn, vacant frames may be used. Sow the seeds 1ft. apart, and later on a mulch of half-decayed manure may be given. Keep the plants well supplied with water, and bear in mind that the lights will not be needed until the nights become cold and when there is a possibility of frosts.

FRUITS UNDER GLASS.

Peaches and Nectarines.—When the fruits have been gathered from the early trees, it will be advisable to cut out as much of the old wood as possible, at the same time tying the new growths so that they will receive the full benefit of the sun. If insect pests are present, the trees ought to be sprayed with an insecticide, or the house vaporised, the former for red spider and the latter for aphides. The ventilators may be open to their fullest extent both day and night, and while the foliage is healthy the trees may be syringed with clean water late in the afternoon when the weather is fine. Trees that are weak, either from age or over-cropping, should have their roots lightly mulched with decayed manure; the roots will also benefit by occasional applications of liquid manure. Young trees that show a tendency to grossness will not require any stimulants. In the later houses the fruits are swelling, and a much better flavour is secured if plenty of air is afforded during warm weather. See that the border does not become dry, and syringing the trees both morning and afternoon should be continued as long as possible, but the latter spraying should be done sufficiently early for the fruits to dry before sunset. See that the trees are kept free from insect pests.

Strawberries.—Runners layered in pots should be removed from the parent plant directly they are well rooted, and the pots then plunged in ashes until the time arrives for placing the plants in their fruiting pots.

THE FLOWER GARDEN.

Cuttings.—At this season it is a good plan to make up a hot-bed for propagating purposes, and when the rank heat has escaped and the temperature is on the wane, it will be ready for use. A layer of sandy soil may be placed inside the frame, or pots may be employed for the cuttings. Forsythias, escallonias, helianthemums, etc., may be propagated now and during the next few weeks.

Pruning.—This year the philadelphuses have been exceptionally fine, and now that they have passed the flowering stage the old growths should be cut out, also the weakest of the new shoots if they are overcrowded. The deutzias may be afforded similar treatment. Shrubs take a lot of nourishment out of the soil, so wherever possible a mulch of decayed manure should be given.

Dahlias are now making headway, and it will be necessary periodically to tie the growths to the stakes and thin the shoots where they are numerous. It pays to do this, because the remaining stems will be stronger and the flowers of better quality. Where the soil is poor, mulch the roots with manure.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Beetroot.—This year early sown seed has done very poorly and therefore a later sowing had to be made; this has done better, and so the work of thinning is consequently much later. If there is still a scarcity of crop, the thinnings, if carefully taken up and transplanted, will grow quite well. The plantlets should be well watered after they are set out, and sprayed or watered for a few evenings in succession if the weather is dry.

Borecole—or as Scotch folk call it greens or curly kale—is a useful winter vegetable, growing splendidly in nearly any kind of soil or situation. Where plants are still to set out, they need not be spaced quite so far apart, for, as a rule, they do not grow so large as those planted two or three months earlier.

Broccoli.—Where blanks have occurred, these should be filled without further delay. Even where planting has been retarded owing to one cause or another, good breadths may still be got in with every chance of success. We have planted that fine late variety Methven's June on August 1st and had good heads for cutting by the middle of May of the following year.

Cabbages.—The Winningstadt and Savoy types should also be set out, so that good supplies of vegetables will be available throughout the winter and early spring months. These late set out plants do not produce extra large heads, but they stand the winter better, and so prolong the supply.

Tomatoes.—The main crop and other plants bearing heavily will benefit from a top dressing of decayed farmyard manure, or fresh potting mixture. Continue to pinch out all unnecessary growths, so that the plants are kept within bounds, and the tomatoes obtain nourishment.

THE FLOWER GARDEN.

Herbaceous Borders. — When hardy plant borders are infested with perennial weeds, constant forking and weeding is really the only way to keep the ground clean. However, it is often the case that gout or bishop's weed and couch grass, etc., are interwoven with the roots of many plants. The only cure is to mark such plants now and dig them up in the autumn, or when the borders are bare, and if they cannot be properly cleaned have them thrown away.

Myosotis.—Seedlings should be sufficiently advanced to be set out now 3ins. or 4ins. distant from each other in lines 1ft. apart. If, however, the seed was sown thinly, and only a bed or two required from which to obtain cut flowers, the plantlets need not be moved, as they will flower quite well under such treatment. Young wallflower plants from late sowings should also be set out in lines 1ft. apart, allowing at least 6ins. between each plant in the lines.

THE HARDY FRUIT GARDEN.

Pruning.—It is now a good time to go over the wall and other fruit trees and cut back to half their length the current season's growth. This will allow sun and air to reach the fruits and so hasten the ripening and colouring. Shoots required for extension or to fill in should not be cut back.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.)
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Nierembergia frutescens is a very beautiful and graceful plant for the greenhouse, and may be raised either from seed or cuttings. If seed is sown at this time, good plants for flowering next summer will result. The plants should be pinched several times to preserve a bushy habit. They grow quite well in any good potting compost, and only require at all times perfectly cool greenhouse treatment. In the South at least they are more or less hardy. Cuttings root readily under a bell-glass in a cool greenhouse, and this method of propagation is useful for increasing any good forms, for in a batch of seedlings white-flowered varieties sometimes appear, as well as deeper-coloured forms. N. filicaulis and N. gracilis are two other species that are well worth growing.

Hydrangeas. — Continue to propagate according to requirements, inserting the cuttings singly in small pots and standing them in a close propagating case. Plants that have finished doing duty in the conservatory should have their flowering shoots shortened back, and when starting into fresh growth have a shift into larger pots. After repotting it is an advantage if the plants can be kept fairly close in a house for a week or so, and then stand them outdoors in a sunny position where the wood will have a good chance to get well ripened.

Primula malacoides.—Seed of this useful primula should now be sown in a cool greenhouse. This primula is very pretty and popular for decorative work, and it will grow and flower freely in quite small pots. It is also very effective when several plants are grown together in shallow pans. Primula malacoides is nearly hardy and only requires cool greenhouse treatment. It grows freely in any good potting compost, and its successful cultivation presents no difficulty, although during the winter damping off should be guarded against. Take care to keep water out of the closely packed rosette of leaves.

Primula Forbesii is very useful, especially for small unheated greenhouses. If seed is sown at this time the resultant plants will succeed under the same treatment as that indicated for P. malacoides. This primula may be grown singly in a 60-sized pot, or three or four plants placed in a 48-sized pot.

P. Cockburniana and P. Veitchii.—Although both these primulas do quite well outdoors in the South, they are well worth growing for the cool greenhouse. A stock of plants is easily raised from seed sown at this time.

P. japonica and PP. pulverulenta, Beesiana and Bulleyana, of which there are now many beautiful varieties and hybrids, are all worth growing for the cool greenhouse. As they are all strong-growing plants, the best results are obtained by lifting strong, well grown plants from the open and placing them in suitable-sized pots during the autumn.

P. Forrestii, only hardy in the West, is an interesting and distinct plant which should be grown for the unheated greenhouse. It is easily raised from seed sown at this time, and can be grown in cold frames. As it is a native of limestone cliffs in China, lime in the potting compost is essential. For this purpose old mortar rubble may take the place of sand in the potting compost. This primula in its native state is a long-lived perennial, and under cultivation is at its best the second and third year from seed sowing.

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Sweet Pea Plants Failing (E. J.)—The plants are affected by a fungus called Black Rot. It begins its destructive work while the plants are much smaller, but the final stage is rapid, the plants suddenly dying owing to the whole of the stems being surrounded by the fungus. The soil is deficient in lime. Very little can be done at this stage to prevent other plants dying; the lime should be applied in the autumn, in sour soils, at the rate of 6oz. per square yard.

Stocks Dying (Mrs. B. S. R.).—A fungus called Pythium de Baryanum is the cause of the plants dying off at the soil level. Really, the mischief begins at an early stage of the plants' growth. The necessary transplanting from one kind of soil to another will, frequently, delay, if not cure, the disease. But where the soil in the flowering quarters is also impregnated with the fungus the plants will die suddenly, as our correspondent's have done. Liming in the autumn is the remedy and, in addition, some old mortar rubble should be mixed with the soil in the spring prior to planting, to render the ground sweet.

Plants for Growing in a Moist Soil (C. P.).—We suggest that our correspondent plants irises of the June and July flowering species in some of the beds. The following are suitable and beautiful varieties: Monnieri, Monspur, sibirica, s. Snow Queen, s. orientalis and spuria, W. A. Tait. In other beds, or judiciously mixed with the irises and other plants, grow spiræas, trolliuses, primulas for early flowering, geums, Saxifraga peltata, Lobelia cardinalis and a few funkias. These will afford more satisfaction than roses and shrubs in a water-logged soil.

THE ROSE GARDEN.

Rose-leaf Black Spot (W. J.).—The treatment which our correspondent has given — spraying with potassium sulphide, ½oz. to 1 gallon of soft water—is the correct one. The operations should be carried out very thoroughly. Procure the rock sulphide, purchased from a bottle and retained in another till actually used, as exposure causes loss of strength in a few hours even. A solution of this kind will not block any ordinary syringe. We do not know of any other more efficacious fungicide for the purpose.

Planting a Rose Garden (B. F., West Surrey).—We recommend the following plan, and we feel sure that our correspondent will be pleased with the result. The five long beds should be planted in pairs; the two outside, shortest beds each filled with Pride of Waltham (flesh, shaded rose), Mme. Eugene Verdier (flesh-rose), Mrs. John Laing (rich pink), Ulrich Brunner (carmine-rose) and Captain Hayward (carmine-crimson), the last colour being in the beds next to the two central ones in our correspondent's plan. Hybrid teas for the two last named: Althea, Admiral Dewey, Avoca, Beatrice, Bessie Brown, Betty, Clara Watson, Countess of Gosford, Dora, Dr. Campbell Hall, Duchess of Albany, Earl of Warwick, Edward Mawley, Etoile de France, Freda, George Reimers, Gipsy, Grace Molyneux, Gustave Regis, His Majesty, J. B. Clark, Killarney, Lady Barham, Lady Battersea, Lady Pirrie, La Tosca, Mabel Drew, Mme. Mélanie Soupert, Margaret, Melody, Mrs. Aaron Ward, Mrs. Arthur Munt, Mrs. E. G. Hill, Mrs. Peter Blair, Mrs. Walter Easlea, Othello, Peggy, Pharisäer, Prince de Bulgarie, Richmond, Shandon, Walter Speed and William Shean. These may be duplicated several times or added to in variety. Standards for those two long beds: Antoine Revoire, Betty, Captain Christy, Claudius, Caroline Testout, Countess of Derby, Dorothy Page Roberts, Duchess of Wellington, Duchess of Westminster, Earl of Warwick, Edu. Meyer, Ethel Malcolm, Florence Pemberton, Freda, George C. Waud, General McArthur, Grace Darling, Gustave Regis, Harry Kirk, James Coey, Lady Pirrie, Mme. A. Chatenay, Leslie Holland, Mme. Ravary, Marquise de Salisbury, Joseph Hill, Mrs. Alfred Tate, Mrs. David McKee, Pharisäer and Viscountess Folkestone. The ten large round beds, No. 1, should all be filled with the variety Hugh Dickson. The general effect of this arrangement would be striking and pleasing too.

Rose Buds Eaten by Maggots (H. J.).—The rose buds have been eaten by the maggots of the rose tortrix, Tortrix Bergmanniana. These maggots do a lot of harm in a very short time. Where there are few of them, hand-picking is best, but where numerous, syringe the bushes forcibly with weak quassia solution and immediately scatter dry lime on the caterpillars or maggots on the soil under the bushes; further, to destroy all fallen, vigorously rake the soil to and fro with a sharp-toothed iron rake.

THE ROCK GARDEN.

About Gentians (E. D. B.).—Gentians acaulis requires good loamy soil in an open situation. G. verna likes more grit, in a half shady place, with plenty of moisture when growing. Neither of them flower well in the vicinity of large towns for long.

How to Rid a Rock Garden of Ants (E. E. C.).—Of course drastic remedies, such as pouring boiling water on the soil where the ants have their nests, cannot be applied. Sanitas powder may be used with good results. Sprinkle it freely on the parts and mix it with the soil with the aid of a garden fork or hand trowel. The ants will leave the rockery or go deeper, beyond the roots of the plants.

TREES AND SHRUBS.

Beech Hedge not Satisfactory (E. S.).—The best treatment at present would be to give the hedge a mulch of old decayed manure, watering also about once a fortnight when the weather is dry. It is doubtful whether any of those plants not showing signs of growth will start now. Write to the nurseryman from whom they were purchased explaining the failure. He will, no doubt, replace them at a reduced rate in view of the care given to the plants.

Tree for Shade on Lawn, etc. (G. G., Cobham).—The double white gean, Prunus Avium flore pleno would be a better tree for the purpose than either of the Japanese cherries. It is fairly vigorous in growth. The best type of tree for shade would be a standard with a 6ft. stem. As a flowering tree it makes a most beautiful lawn specimen. Jasminum officinale is the white jasmine. It is very effective on an arch in the open, planted to clothe a porch or against a west wall. Climbing roses for a west wall: William Allen Richardson, Climbing Liberty, Climbing Mrs. W. J. Grant. East wall: Gloire de Dijon or Bouquet d'Or, Madame Jules Gravereaux, Longworth Rambler. South wall: Maréchal Niel, Climbing Niphetos, Bell Lyonnaise.

THE GREENHOUSE.

Narcissus Jonquilla from Seed (E. S., Hythe).—If our correspondent has the seed of N. Jonquilla it should be sown at once in pans and wintered in a cold frame. Here it should remain until 1926, when if it has done well it will have produced little bulbs. These may then be planted in a bed outside. Flowers will appear in about 1928 or 1929.

Statice profusa (E. W., Oakham).—This is a cross between S. puberula and S. Halfordii, a greenhouse evergreen plant, propagated by seeds or cuttings. It is easy to grow the young plants in a cold pit or frame. Throughout their growth these plants thrive best in a sandy, fibrous loam. At the final potting a small proportion of fibrous peat may be added to the compost.

FRUIT GARDEN.

Cherry and Gooseberry Leaves Damaged ("Howdenlea").—Judging from the appearance of the leaves of the cherry they have been bitten by a small bee that bites the leaves of roses and many other kinds of plants. These bees do not eat the leaves, but build their nests with the bits. The damage, except to roses, is rarely serious. The gooseberry leaves are eaten by the grubs of the sawfly. The eggs are laid early in the season and the resultant grubs soon eat up the leaves of whole bushes. Sprinkle soot and lime, or even fine grit and soot on the bushes to prevent the second brood in July. Spraying with Abol is a good remedy.

MISCELLANEOUS.

Paint for Labels (E. S.).—Our correspondent does not say whether the labels are made of wood, zinc or other metals. Gum shellac three parts, india-rubber half a part, should be dissolved separately in vessels in ether free from alcohol. When in a dissolved state mix the two and keep in a bottle tightly corked till required for use. Great care should be taken with this operation. A mere smearing of written labels will be sufficient to prevent obliteration of the writing for many years in all weathers. Pencil writing on wooden labels may be kept clear and preserved by simply painting over with an oil varnish.

Names of Plants.—A. H., Winchester.—1, Œnothera fruticosa; 2, Buphthalmum salicifolium; 3, Geranium sanguineum; 4, G. Endressi; 5, Campanula Portenschlagiana.——C. E. BOOK REVIEW

THE author of this interesting little book "Outlines of Fungi and Plant Diseases," by F. T. Bennet, B.Sc. (Lond.). Macmillan, 7s. 6d.), is to be congratulated on his presentation of such a large and somewhat complicated study in such a limited space.

The book is divided into two parts, Part I dealing with a general chapter on the fungi—their structure, systematic position and classification. Then follows a short chapter on each of the sub-groups—Phycomycetes, Ascomycetes and Basidiomycetes—with a short description of lichens bringing the part to a close. Part II deals with plant diseases, first from a general aspect, with a brief reference to resistance and immunity to disease. Each of the sub-groups are then taken up in detail and various types of these groups discussed. Quite a careful general review of each of the groups is given which serves to correlate the various distinctions found between types. The merits and demerits of a type system have been discussed *ad nauseam*, but one has to admit that, provided the student has the idea of relationship between what appear superficially isolated types, there is at present no system to surpass it. In this booklet the relationship between types is pointed out, and the student cannot but realise that such types are connected and one can gather that there is some co-ordinating force at work. Such ideas are exceedingly useful to cultivate in the mind of the student. Useful appendices on fungicides and soil sterilisation, fungi injurious to livestock, a *résumé* of the Destructive Insects and Pests Act, are most necessary acquisitions. The book is completed with quite a handy index. It is also remarkably free from errors in spelling, and such carefulness is to be admired.

Unfortunately, the numerous diagrams which are to be found throughout the book are scarcely up to the standard of the text. Several are somewhat inaccurate and many are not at all clear to the student to whom the subject is entirely new. One must, however, keep in mind the low price, and should be glad to have so many diagrams in such a limited space. Again, the subject of references to literature to the various chapters bears notice. The book is primarily for the use of students of agriculture and horticulture, and as such the references given are not at all suitable. For use of pure science students of the subject they admittedly are, as many are more cytological—*e.g.*, Gwynne-Vaughan (1922)—rather than dealing with a general account of the subject under discussion. It is unfortunate, also, that there is no mention whatever of the Bureau of Plant Industry papers or other American reports which contain much of the latest work on the subject of plant disease. A concrete example will serve to illustrate the point—there is no reference to any of the later papers by Mr. F. T. Brooks on Stereum purpureum, nor to those by Butler on leaf mosaic. Why always refer to De Bary and other old works on the subject? Such books, even although they are standard works, are not easily procurable for the majority of students and naturally cannot be consulted. Again, in many cases, a knowledge of German or French is required when referring to such works.

These small faults detract but little from the use and value of such a book to general practitioners of horticulture and students of agriculture. It is a volume which contains much that is useful and essential to him who wishes to understand the rudiments of mycology and plant disease, and the information is presented in a style almost without exception simple and lucid, although of necessity a few technical terms creep in. The book is excellently printed throughout, for which due credit should be given to the publishers.

Announcement
by
Abol Limited

THE proprietors and manufacturers of the well-known Abol Garden Specialities wish to announce the expansion of their Laboratory, and increase of their Laboratory staff.

A wider range of specialities is being put on the market, and already they they are offering, and soliciting enquiries for the following Special Manures:

Rose
Sweet Pea
Chrysanthemum
Tomatoes
Potatoes
and Hop Manure.

All these are thoroughly first-class, and will be found to uphold the reputation for reliability, which has been associated with the name Abol for many years.

Abol users are invited to enlist the services of our Research Department, which includes an expert on soils and fertilizers.

Anyone doubting the suitability of the water they use for spraying purposes, should send us a specimen for analysis, which will be done free of charge.

Write to-day for full particulars—

Abol Limited,
9, Beltring,
Paddock Wood, Kent.

Sole proprietors and manufacturers of Abol Non-poisonous Insecticide, Patent Syringes, etc.

Descriptive folders and Guide to Garden Pests, gratis and post free.

SOCIETIES

THE NATIONAL SWEET PEA SOCIETY'S SHOW

THE above named Society held its annual show at the Royal Horticultural Society's Hall on Thursday and Friday, July 10th and 11th. The exhibits were numerous and the quality of the blooms excellent.

Messrs. R. Bolton and Sons had a very tastefully arranged exhibit on which Wembley, Empire, Mammoth and Powerscourt were outstanding sorts.

Royal Sovereign, Hebe, Mrs. Tom Jones and Daffodil were prominent sorts shown by Messrs. Dobbie and Co.

Messrs. E. W. King and Co. had a well arranged exhibit. Outstanding sorts here were Tom Sykes, Pimpernel and Constance Hinton.

On Messrs. S. Bide and Son's stand Royalty, King Mauve, Warrior and Charming were conspicuous.

Diana, Charming, Wild Rose and Grandeur were well shown on Mr. J. Stevenson's exhibit.

Messrs. Sutton and Sons had two exhibits on which the following sorts were conspicuous: The President Harding, Burpees, Giant White, Powerscourt, Geo. Shawyer, Mrs. Tom Jones and Tangerine.

Ravenswing, Lord Lascelles, Tangerine Improved, Hawlmark Pink Improved and R. F. Felton were outstanding sorts on Messrs. Ireland and Hitchcock's stand.

The competitive classes were well contested, especially so in the section for novices. The entries in table decorative classes, however, were few.

On Friday morning a trip was made by char-à-bancs to Syon House, Brentford, where the sweet pea trials were held.

In spite of the present spell of drought the blooms were exceptionally good. Unfortunately the majority of blooms were under number. After inspecting the trials the party proceeded to the Imperial Restaurant, Kew Green, Kew, where lunch was served. After lunch the party was shown round the Royal Botanic Gardens by Mr. A. C. Bartlett and Mr. Gerald Hillier.

WOLVERHAMPTON SHOW.

THE Wolverhampton Floral Fête of 1924 will surely be registered as one of the finest provincial shows ever held. Increased numbers of exhibits, totalling 644 entries, most tastefully arranged over an area of 40,000 square feet of ground in West Park, covered by 65,000ft. of canvas, should certainly defy the rumours in the district of the possibilities of discontinuance owing to lack of support, and it would be a great pity, after such a magnificent Show, were this ever to take place. It was decidedly a rose show, for the wealth of the queen of flowers was lavishly displayed on this occasion and, in the opinion of the judges, equalled and possibly surpassed the June Show in Regent's Park of the National Society. Not only were there literally banks of roses, but the colours, shapes and arrangement were of the highest perfection. Delphiniums, too, were in great evidence, and made a splendid show; while sweet peas, a credit to both amateur and professional growers, were a close third in the floral classes. Vegetables were strongly supported, and a credit to the Exhibition; but mention must be made of the fact that fruit entries were below the average, and it should be a recommendation to the Committee of the Fête to include in their schedule classes with the incentive necessary to attract first-class fruit exhibits, which can easily prove one of the most attractive and fascinating sections of a good show.

One feature of the exhibits that deserves special mention was the really high-grade of the table decoration and allied entries, as these often form one of the weakest sections at provincial shows of various classes.

Individual entries cannot be dealt with throughout, but a number call for special note. Mr. J. Cypher (Cheltenham), well known for his magnificent floral groups and exhibits, on this occasion probably excelled any that he has staged previously. It was the winning effort for the principal competitive class, and was magnificently conceived and carried out with first-class miscellaneous plants (particularly fine were the orchids), bedded with fine taste in a groundwork of suitable subjects. G. H. Kendrick (Edgbaston) and W. A. Holmes (Chesterfield), the second and third prize-winners, also exhibited splendid groups, either of which would have easily proved leading groups of sterling merit had their competitors been absent. Close to these was a group of magnificent begonias, staged by Messrs. Blackmore and Langdon, which made a wonderful splash of colour. Competitive vegetables, well staged and of fine quality, were set up by Mr. F. Streeter (gardener to Major Pam), a rising young exhibitor of first-class vegetables. Trade exhibits of non-competitive order were most attractive. Bakers of Codsall, with a design forming an entrance to a formal water garden, with terrace, provided a most interesting piece of work; Ellison's of West Bromwich sent a fine group of greenhouse plants; John E. Knight and Sons of Wolverhampton staged an excellent vegetable group; and Webbs of Stourbridge combined the utility of vegetables with the beauty of flowers, with splendid taste; and there were many more such exhibits, deserving of the mention which only space forbids.

THE EDITOR'S TABLE

WE have received from Mr. T. Smith of Newry some flowers of some of the hybrid escallonias, of which not enough use is made of them commensurate with their hardiness and freedom of growth and flowering. Donard Seedling is a pretty apple blossom colour and very free. Edinburgh or Edinensis, with flowers of a similar colour to Dorothy Dennison rose, is remarkably effective at a distance. It also has the useful habit of producing a crop of flowers in the autumn. Gracilis alba, pure white, is a very pretty shrub when in flower. Langleyensis is one of the finest hardy flowering shrubs of recent additions. Its long, arching branches wreathed with bright red flowers, give a brilliant effect. It is best in the twilight, when the colour becomes blood red. Philliptana, one of the parents of all the above, still ranks among the best of white summer-flowering shrubs. There was also a flowering spray of Trollius pumilus yunnanense. T. Ledebouri or sinensis was stated to be the latest of the globe flowers, but it is over before the above is in full bloom. Its large single rich golden yellow flowers are very handsome and remain a long time in good condition. Its height is about 18ins.

TRADE NOTES

MESSRS. SUTTON'S SUCCESS IN BRAZIL.

British horticulturists will learn with pleasure that at the Brazilian Centenary Exhibition, held at Rio de Janiero, the International Jury awarded to Messrs. Sutton and Sons of Reading a medal and certificate for the seeds supplied for sowing in the Gardens of the British Pavilion, where the floral display was the admiration of all visitors.

FERTILISERS.

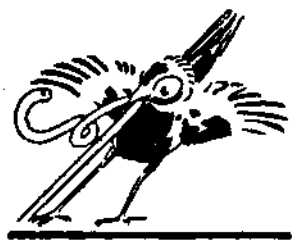
MANY readers are, no doubt, already familiar with the specialities of Messrs. Robinson Brothers, West Bromwich, and have used with success their Multiple plant food and Carmona fertiliser. Those who have not yet tested the merits of these specialities are advised to do so immediately, for even now they will reap a rich reward in a bigger yield of their root crops; and this experience will induce them next year to take fuller advantage of the benefits which a use of Messrs. Robinsons' products invariably brings.

VERMOL kills worms and grows good grass.

All the famous GOLF, TENNIS, BOWLING and CRICKET CLUBS throughout the world use—

HE can only tackle them one at a time BUT—

VERMOL gets the lot.



VERMOL

The Worm Destroyer and Grass Tonic.

What users say of Vermol—

THE GLENEAGLES GOLF COURSES.

"We are now using the three tons of VERMOL WORM KILLER recently supplied and the results are really amazing. The worms are coming up in thousands and everybody is delighted with the marked improvement of all the treated Greens.

"I can recommend VERMOL with every confidence to all Golf Clubs."

You will, I hope, forgive my questionable method of arresting your attention. The question itself is really one of moment to you.

Do You know this Booklet?

If you know it, there is no question at all about it: you send for your copy every year and wouldn't settle your new list without it.

"MY FAVOURITE ROSES AND WHY" is a text book to give any beginner confidence, but it aims to be a YEAR BOOK and a ROSE ANNUAL that will keep an expert up to date.

Of course it is a Catalogue, too—it wouldn't be free and post free if it weren't; but don't hesitate to write for it because you can never send me an order—if I may say so—it isn't your order I'm after, it is your appreciation.

THE GARDEN

VOL. LXXXVIII.—No. 2750. AUGUST 2, 1924.

WE WOULD ASK OUR READERS TO REMEMBER THAT "THE GARDEN" IS PRODUCED FOR THE BENEFIT OF ALL GARDENERS. WE ARE ALWAYS PLEASED TO CONSIDER ARTICLES OR NOTES ON ANY HORTICULTURAL SUBJECT.

A FAIR SETTING FOR A RAMBLER ROSE; SEDUM ALBUM FLOWS OVER THE STEPS, WITH LAVENDER AT THE SIDE. THE EFFECT IS NEARLY PERFECT, FOR THE COLOURS BLEND THE ONE INTO THE OTHER.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience, which the Service Department affords, of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS.

GARDENING BOOKS

PRESUMABLY, if one is interested in gardening, one attaches a certain amount of importance to gardening literature, but with the immense output of works on this most important subject and with only a limited pocket it is sometimes difficult to make a choice. Therefore, with some diffidence, I am going to give a short list under subjects of some of the volumes which I find most useful, not only as works of reference, but also, in the majority of cases, as books which make interesting reading.

THE HISTORY OF GARDENING.

"A History of Botany in the United Kingdom from the Earliest Times to the end of the 19th Century," by J. Reynolds Green (J. M. Dent and Sons, Limited). Infinitely the best book on the subject; exceedingly interesting to read and without fault.

"A History of Gardening in England," by the Hon. Mrs. Evelyn Cecil (John Murray). Classifies gardens and fixes the date to which they belong; is full of garden lore and out of the way information.

"The Old English Herbals," by Eleanour Sinclair Rohde (Longmans, Green and Co.). Gives concise and useful information about the earliest of English garden books, many of which are of extreme rarity and all of which are difficult to read and dull if taken in large doses.

GENERAL GARDENING BOOKS.

"The Illustrated Dictionary of Gardening, A Practical and Scientific Encyclopædia of Horticulture for Gardeners and Botanists," edited by George Nicholson; five volumes (L. Upcott Gill). Although out of print and rather out of date, this is still a standard work on horticulture, and is a necessity for all who go in for gardening on a large scale.

"Johnson's Gardening Dictionary" (Routledge). A little out of date, but still a most useful book.

"A Manual of Cultivated Plants. A flora for the identification of the most common or significant species of plants grown in the Continental United States and Canada for food, ornament, utility, and general interest, both in the open and under glass," by L. H. Bailey (Macmillan and Co., Limited). Although many plants grown in this country are not found in this book, yet it is of great use to all who are serious gardeners.

"Gardening for Beginners," by E. T. Cook (*Country Life* Library). The most comprehensive work for the beginner or the amateur who is only able to give a limited portion of his time to his garden.

"A Glossary of Botanic Terms with their Derivation and Accent," by Benjamin Daydon Jackson. (Duckworth and Co.). Explains the numerous Latin and Greek terms used in the science of gardening and is invaluable.

THE HERBACEOUS GARDEN.

"The Herbaceous Garden," by Alice Martineau (Williams and Norgate). Gives useful information about this form of gardening with selected lists of plants.

"Colour Schemes for the Flower Garden," by Gertrude Jekyll (*Country Life* Library). The standard work on the subject.

"Annuals and Biennials: Their Uses in the Garden," by Gertrude Jekyll (*Country Life* Library). Full of information.

ROCK GARDEN.

The late Reginald Farrer was so unexcelled in this branch of gardening that I confine my list to three of his books.

"The English Rock Garden," two volumes (T. C. and E. C. Jack, Limited). The most comprehensive book on the subject.

"Alpines and Bog Plants" (Edward Arnold). A smaller work than "The English Rock Garden" and considerably earlier in date, but of great assistance to all alpine gardeners.

"My Rock Garden" (Edward Arnold). Giving his experiences of growing rock plants in his own rock garden in Yorkshire.

TREES AND SHRUBS.

"Trees and Shrubs Hardy in the British Isles," by W. J. Bean, two volumes (John Murray). The most comprehensive book on the subject and an absolute necessity.

"Gardening for the Twentieth Century," by Charles Eley (John Murray). Although the title is deceptive, this book deals entirely with trees and shrubs and the author's experiences in growing them.

"The Cultivated Evergreens," by L. H. Bailey (Macmillan and Co., Limited). Although written for the United States, this book is of great value to foresters and gardeners in this country.

"Shrubs for Amateurs," by W. J. Bean (*Country Life* Library). This volume is not yet published, but Mr. Bean has permitted me to read the proofs. I am sure that this book will be of great value to all who wish to make selections of the best flowering shrubs for their garden

SILVER-LEAVED ROCK PLANTS

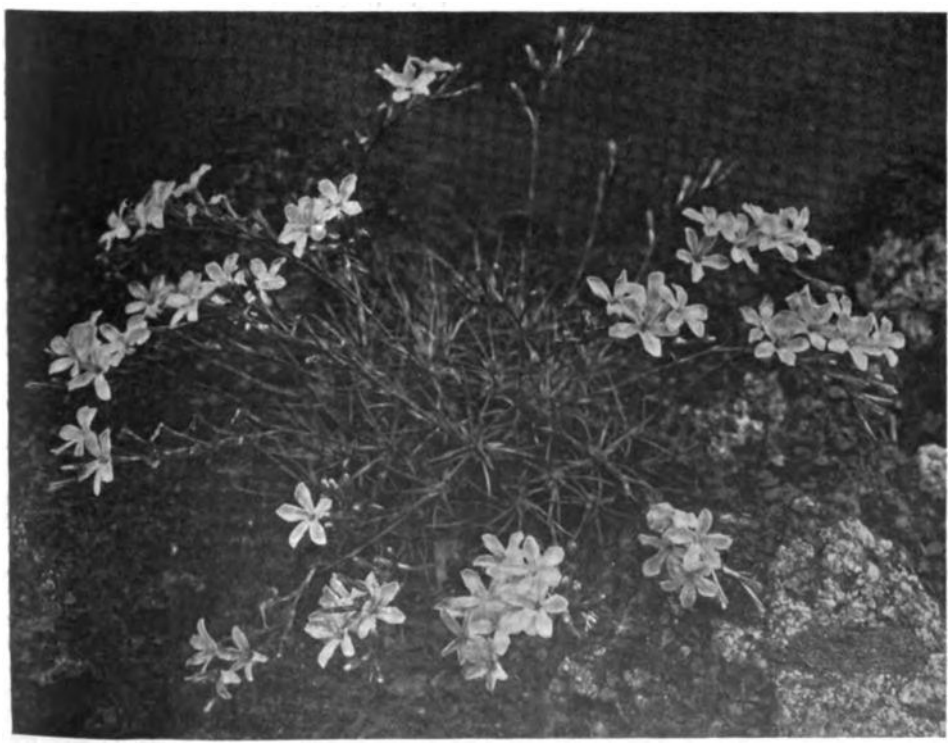
THIS ARTICLE TELLS OF A FEW ROCK PLANTS FOR DECORATION EITHER IN OR OUT OF FLOWER.

SILVER or grey-leaved plants are usually quite attractive when only the foliage is taken into consideration; some, in addition, have fine showy flowers, while others only possess very uninteresting and insignificant blossoms. In the dull dreary months of winter the rock garden can always be made brighter if several silver-foliaged plants are admitted, provided that they are planted here and there among the green masses that usually predominate. And again, silver foliage can be employed very largely in colour-scheme ideas; what could be more pleasing than to see the dazzling scarlet blossoms of Dianthus Atkinsoni peering through a mass of lacy, silvery wands of Artemisia frigida, or to see, in early spring, odd flowers of the golden yellow Crocus susianus poking their way through a dense silver carpet of Raoulia australis. But in this article I only intend to suggest a few items that have handsome grey or silver foliage and which are decorative either in or out of flower.

ARTEMISIA FRIGIDA, already referred to, is an almost indispensable plant for graceful silvery effects. Its finely cut foliage presents a dainty appearance of glistening silver some 6ins. or so high, while in summer the flower spikes reach up to 18ins. high; but, although the flowers are dull and uninteresting, the spikes are well furnished with leaves, and so help to make up for the deficiency of its flowers. It will thrive in almost any good ordinary soil and in a warm sunny aspect. It should not be planted too near any small choice alpines, as it is of rather a robust habit. Another artistic wormwood is A. canescens, which, again, requires ample space, with grey foliage, much more finely cut and divided than A. frigida, and bearing flowers equally inconspicuous. Nevertheless, it is a handsome plant, which has the peculiar beauty, when grown in a mass in autumn, of changing the leaves on the lower part of the stems to a shade of colour which gives the appearance of a purplish mist. Usually it is about a foot high and perfectly hardy, and responds well to an ordinary well drained compost in full sun, either on the rock garden or border.

POTENTILLA NITIDA.—Here we have one of the choicest and daintiest of its race, a perfect cliff dweller and a limestone lover. It is prostrate in habit, and makes either a carpet or a curtain (according to position) of shining silver leaves, which in summer is studded with numerous large rosy pink blossoms only an inch high. In cultivation, however, it has the reputation of being a shy bloomer, which is perfectly correct if it is allowed to wax fat in some spacious pocket of rich soil; but should it be placed on a sunny ledge or in a deep crevice where the soil is poor and gritty, then the chances of flowering it well are greatly increased. There is also a white version of this, namely, P. n. alba, requiring exactly the same treatment, and, although a first-rate alpine, worthy of admission into any rock garden, cannot equal the beauty of the pink type.

RAOULIA AUSTRALIS, A NEAT MINUTE CARPETER FOR A WARM, LIGHT, GRITTY SOIL.



A PRICKLY THRIFT WITH SILVER FOLIAGE, ACANTHOLIMON VENUSTUM.

SAXIFRAGA COCHLEARIS MINOR.—From the large family of saxifrages one is able to select a good assortment of choice grey-leaved varieties, but I am picking out one or two that I believe may prove suitable as silver-foliaged plants. In S. c. minor we have an extremely good alpine, very easy of culture, and one which enjoys a happy, sound constitution. It is a typical crevice plant for a sunny aspect, preferably in a good limy mixture. It forms firm dense hummocks of neat silvery small rosettes, from which, in June, it throws out numerous 6in. flower spikes, dark red in colour, which bear abundant dainty white flowers. By the way, this is the plant that so very often has been grown as the rarer S. valdensis, which it in many ways resembles. It is, however, absolutely distinct, being a much faster grower, having larger rosettes and an entirely different inflorescence.

SAXIFRAGA LONGIFOLIA.—The queen of saxifrages and a great favourite,

Digitized by Google

hailing from the limestone cliffs of the Pyrenees. The one and only drawback to the plant is that it dies after flowering. It would be wise to provide it with a good fat soil to encourage growth instead of flower; grown as such it may be kept for several years without flowering, and the large silver rosette of long narrow strap-shaped leaves is almost as handsome as the flower spike, looking beautiful at any time of the year. A well grown specimen may have a rosette as large as a tea-plate, and is capable of producing a 2ft. or 3ft. flower spike composed of scores of white flowers, most graceful in appearance, particularly so when it is planted on its side, which is advisable when possible. It loves a crevice position in sun; here its rosette will lie flat to the rocks on either side of it.

CERASTIUM ALPINUM LANATUM.—This plant has been well and truly named the "chinchilla plant," on account of the silvery woolly hairs that almost envelop it when the growing season has come to an end. During the making of growth it looks almost green, but throughout the winter it appears to be a mass of silver fur. The flowers are large and white and are freely produced, with practically no trouble whatever; all that is needed for successful culture is a warm sunny position in any ordinary, well drained soil. Its height is about 3ins.

ANTHEMIS HAUSSKNECHTII.—The foliage of this item is particularly noteworthy, being of such an intense grey as to appear almost white. The leaves are bluntly cut and are up to 6ins. in length; while the rich golden flowers, of a large daisy type, are borne singly on 12in. naked stems. It requires abundant space, as it is a vigorous grower, making large, handsome tufts. For the border, it is also a good plant, especially where good foliage effect is desired. It will thrive in any ordinary soil.

DIANTHUS CÆSIUS.—Here we have the "Cheddar pink," a fine British native (which, I am sorry to learn, is getting scarce in its native haunts), and also one of the fifty best rock plants. It is a good doer both for the rock garden and the wall garden, and is extremely partial to lime in any gardening form. The foliage, which is a pure grey, is formed into a dense cushion an inch or so high, and the flowers are of a lovely clear warm pink, deliciously fragrant, profusely borne in June on 4in. to 6in. stems.

WAHLENBERGIA PUMILIO is a charming little alpine that will flourish in limestone scree or in a tight crevice in full sun. The plant makes a tuft of shining silver grass-like leaves 2ins. high. From these appear, in June, numerous dainty cups of an amethyst shade. It may be propagated by seed or cuttings, but it is an excellent perennial.

ACANTHOLIMON VENUSTUM.—A rather rare member of the prickly thrift tribe, also one of the handsomest, that builds itself into a hummock of grey spiny foliage. It looks particularly well when established in a narrow crevice, and likes a hot sunny position in a gritty limestone mixture. The 6in. flower spikes bear from six to twelve bright pink blossoms, arranged alternately along the spike.

PENTSTEMON RUPICOLA (syn. P. Davidsoni).—A perfectly prostrate woody pentstemon with grey-green, fleshy, oval leaves and flowers of a luminous port-wine colour. It is a fine plant, suitable for filling a tight crevice where it can grow over a rock face to which it will keep close and flat. It is not rampant in its growth, but is steady and genuine in merit. A light gritty compost (preferably limy), together with all the sunshine available, should be most satisfactory.

ERODIUM CHRYSANTHUM.—This is somewhat rare in cultivation, but it is, nevertheless, a very fine species, having most beautiful silvery fern-like foliage arranged in a generous tuft. The leaves are large, covered with silky silver hairs and, generally speaking, have the appearance and touch of velvet. Its flowers, of a pale sulphur colour, just ascend above the foliage, about 6ins. in height. It requires a deep gritty and well drained compost in a sunny aspect, otherwise it is of easy culture and a fine hardy perennial.

RAOULIA AUSTRALIS.—A neat, minute carpeter for a warm, light, gritty soil, with foliage of glistening silver and flowers hardly worthy of note, being small, creamy and unattractive. It is quite an easy doer, and used as a carpeter has very few rivals for brilliancy of foliage effect. To work a little sand occasionally into the carpet it forms, greatly assists in warding off the brown patches that sometimes occur and mar its beauty.

F. BARKER.

WAHLENBERGIA PUMILIO, A DAINTY SCREE PLANT.

A SILVER-LEAVED SAXIFRAGE, S. COCHLEARIS MINOR.

A MAGNIFICENT SHRUB

WHEN Mr. Wilson, on his way back from his southern travels, two years ago, paid a visit to the Verrières Arboretum near Paris, we were surprised to see him making a dash in the direction of a specimen Schizophragma integrifolia, covered with its curious and showy bracts. This, he said, was a great surprise to him, for he had not seen one of that species in flower since he collected the seeds in China.

It is no exaggeration to say that S. integrifolia is a most striking shrub. For any one who has seen it in flower, it is certainly a sight not easily forgotten. The large bracts, creamy as they develop, become white with age and measure as much as 3ins. in length and 2ins. in width. They are borne on the shrub in June and July and last for quite a long time. The wind helps in making them conspicuous. The foliage which is very large, deep green, and most ornamental is a fine setting for the bracts. As is the case in all schizophragmas, the pygmy white flowers in the centre of the raceme are inconspicuous. It is surprising that such a beautiful shrub has not spread more rapidly since its introduction into Europe, fifteen years or so ago. The reason is probably that few people have seen it in flower and realised its beauty. The writer knows of a big Continental firm which put it on the market some years ago, but had to withdraw it from its catalogue owing to an annual sale of ten or twelve specimens only. Another reason is perhaps that it is a comparatively slow grower; but, from that point of view, it is certainly not inferior to Hydrangea petiolaris or S. hydrangioides, two saxifrageous climbers that are planted rather freely in gardens and which are, of course, infinitely inferior as regards showiness. There is no doubt that when the plant becomes better known, it will soon become popular.

WITH LARGE LEAVES AND WHITE BRACTS, SCHIZOPHRAGMA INTEGRIFOLIA.

The propagation of S. integrifolia is easy. As no fertile seeds are produced, as a rule, under our climate, it is done mostly through layering, an operation that is simply and quickly done. Although all positions will probably suit the plant, at Verrières it seems to relish particularly a north-eastern aspect. The wall on which it has been trained is about 8ft. high and is now quite covered. So far, the shrub is rather a shy flowerer, but one can see by the illustration here given that this year nothing more effective could have been wished for. It is quite possible that a more southerly position would suit the plant better as regards flowering, although, as regards foliage and general growth, schizophragma always prefers a shady or half shady situation.

C. L.

SOME RECENT DEVELOPMENTS OF THE BEARDED IRIS

BY SIR ARTHUR HORT, BT.

(*Continued from page* 518.)

I *HAVE* raised seedlings (there are three of them), from the "typical" form, but the result in each case was a *dwarf* plant, and only one of the three has the characteristic inflorescence of germanica. These results, so far as they go, make it probable that I. germanica is a hybrid, which also accounts for its comparative infertility; and so the problem is pushed a stage farther back. What, we must now ask, were the parents, and whence came their wild originals? We cannot, like the ancient botanist, who classified plants as "wild" and "cultivated," and thought that distinction was original, suppose that the ancestors of our plants were, so to speak, created "cultivated." Mr. Dykes, who has himself raised dwarfs from seed of an Eastern germanica called Kharput, opines that one parent was I. aphylla, a dwarf with a branching stem; but this plant is not a native of France. Aphylla loses its leaves entirely in winter, thus, as germanica does not do so, the other parent should be a species which is more or less evergreen and, as Mr. Dykes remarks, "there seems to be no known species which would give the necessary character when crossed with aphylla." So that we must leave the question, with the hope that some may be induced to bring the solution nearer by experiments in seeding.

If the discussion of such a problem seems a bit tedious, I would suggest in self-defence that the study of the geographical distribution of the originals of our garden plants may add a new interest to gardening.

To turn now from the germanica group proper to the miscellaneous crowd formerly called "German irises," Sir Michael Foster, the pioneer to whom all lovers of this fascinating genus owe an inestimable debt, proved the origin of many of these so-called "Germans" by actually raising by hybridisation plants indistinguishable from them. For example, he raised Queen of May by crossing pallida with the plant then known as Sambucina. The whole crowd, he said, had come ultimately from four wild stocks, pallida, variegata, squalens and Sambucina. Since his time Mr. Dykes has reduced the four originals to two, showing squalens and Sambucina to be hybrids derived from the other two. (I would hazard a guess that the dwarfish aphylla should be added to the attenuated list.) Strange as it may appear, then, all the garden forms known before Foster's time (he died in 1907), were due to various crossings of these two (or possibly three) parents and their children. The proper home of pallida seems to be Southern Tyrol; it varies a good deal in stature; I remember Foster showing me a bed planted with some thirty collected forms, to exhibit what he called "the degeneration of pallida, from a plant with stems over 3ft. high down to a dwarf of a few inches." But it is easily distinguished by two characters which mark it off from germanica and other species, the flowers are all set close to the stem, which only branches very slightly, and the spathe-valves enclosing the bud are entirely scarious (not green), so that an unpractised observer might think that his buds had died without

Digitized by Google

opening. (Mention may be made here of I. Cengialti, though it was not known at the time of which I am speaking; it was first introduced by Foster from a scrap of rhizome sent him by a lady friend in a letter from somewhere near the Monte Cengialto in South Tyrol; a larger consignment had been intercepted by the Customs officials. This plant, which occurs in a great variety of shades of violet in the mountains round the Lago di Guida and also on the Adriatic coast, differs only from pallida in having green (not glaucous) leaves and spathe-valves, not completely scarious. I have raised countless pretty and very floriferous seedlings from plants I collected near Riva. It crosses freely with pallida with charming results.)

We come back to the first parent of the older garden forms—I. variegata belongs, says our authority, to the neighbourhood of Vienna, Hungary and the Northern Balkan States. The wild plant is in most of its forms a rather inconspicuous little yellow dwarf; it takes its name from the falls, which are variegated with chestnut or purple; in some forms the fall is edged with a line of bright yellow, which reappears in some of the most striking hybrid variegatas, such as Iris King and Maori King. I have raised, from bee-fertilised seed of the wild plant, a series bearing this character; by the way, one of the batch had pale lilac flowers, showing no trace of the coloration of the seed parent. To variegata are doubtless ultimately due all the yellow, browny or bronze shades in our garden forms.

Aphylla (if it should be added to the list), is a very variable dwarf, with branching stems; it belongs (I quote Mr. Dykes again), to Southern Germany, Bohemia, Hungary and the Caucasus; he adds that the various forms have received nearly thirty specific names, as hungarica, benacensis, biflora, nudicaulis, furcata; we may be grateful to him for simplifying the nomenclature. The colour of the flowers is generally some shade of purple, with a blue or bluish beard. Many of the forms are very desirable garden plants, and this species eludes our mischievous winters by dying down completely.

The "German host," then, of a generation or so back owed its origin to these two (or three) species. Many of these old garden forms survive, and, though certainly some have not the right to do so, which belongs to the fittest, and might well make room for their juniors, some are still of permanent value. I, at least, should be sorry to be without such old favourites as Gracchus, Jacquiniana, Mrs. Neubronner, Maori King, Madame Chéreau and Bridesmaid.

Since Foster's time, and largely as a result of his work, new varieties have appeared by hundreds. The alarming check list issued by the American Iris Society enumerates about 2,500! Many of these new introductions, as well as many of their predecessors, are no doubt superfluous; yet there is an astonishing number which mark a great advance in the old limited range. This advance is largely due to Foster in two ways; first, because he introduced many notable wild forms; and second, because he bred from these and showed us how to breed. Under the first head may be mentioned fine germanica forms from the Near East, as Amas, Siwar, Kharput and Trojana from Armenia and Anatolia, and fine giant Eastern pallidas, as mesopotamica oriental variety, Ricardi and cypriana.

Thus he gave us good new plants and also new blood for fresh creations, though he did not live to carry on his hybridising in this class further than one generation. (It should be said that he was working also at other groups, and in particular devoted himself much in his last years to hybridising in the oncocyclus and regelia groups.).

(To be continued.)

MIDSUMMER AT VINCENT SQUARE

HERBACEOUS and hardy plants were much in evidence at the Royal Horticultural Society's Show on July 22nd. Roses were to the forefront, but showed signs of our trying climatic conditions. On the whole then the standard of previous shows was maintained and in some branches took a step forward, which is to be much appreciated.

One could not but single out, at one end of the hall, the massed array of scented-leaved geraniums shown by the Hon. Vicary Gibbs and raised by Mr. Edwin Beckett. Aldenham has long been famed for its collection of these beautiful pot plants and the high degree of excellence which has been reached in their cultivation and propagation. There were many varieties on show and these were mostly to be admired for the sake of their foliage, with all its varying tints of green.

The familiar zinnias formed the exhibit of Messrs. Dobbie, Edinburgh, and with their several well marked colours, such as white, yellow, orange, magenta, violet and purple, provided a picturesque little army with their giant dahlia-flowered heads nodding on the long, stout and somewhat coarse stems. They are essentially coarse plants, but if the five kinds as shown are massed heavily in a border, then the effect is striking at a distance.

Words of admiration could not fail to find expression when one halted for a moment at Messrs. Kelways' stall, there to be confronted with a truly magnificent and well arranged collection of gladioli. Many old varieties and favourites were to be seen, such as "Marie Studholme," and these maintain their old-fashioned charm even against all new comers, such as their novelty, Gladiolus Langprim Pinkie, which has just originated and has been raised from seed by Messrs. Kelways. It is a cross between primulinus and Gandavensis.

Many plants of Trachelium cœruleum, massed together and fringed with coleus in pots, formed the exhibit of Messrs. Carter. The result might have been more effective had the blue been relieved by a dash of a more vivid colour. The young plants were exceptionally floriferous and should stimulate growers of this sub-shrub into activity. This species is fairly hardy in England and should provide a useful addition to the garden.

Roses were exhibited to advantage by many firms and many old, together with fairly new varieties were massed together with good effect. To mention one or two, perhaps Mr. Pemberton's table took the eye most of all. Here a new hybrid musk, Penelope, is worth a minute. In colour it is a good blush white with yellow centre and shapely petals. The sweet scent of The Adjutant, a two year old variety, could be distinctly felt, with its long oval corolla, rose carmine in colour contrasting well with the yellow and crimson of the many other varieties. Messrs. Easlea's had a tastefully decorated display with such varieties as Los Angelos, Mrs. Henry Bowles and Clarice Goodacre, a good white, standing out. Ophelia, Golden Emblem (yellow tinged with orange), Lady Dixon Hartland (pink), Sovereign and Sunstar (yellow), were to be seen on Messrs. B. R. Cant and Son's stand, while on Messrs. Chaplin Bros. section, Innocence, a pure white with velvety petals of a rather quaint appearance, took our fancy. Other varieties here were Admiration (pink), Souvenir de Claudius Pernet (yellow), Madame Butterfly. Frank Cant and Co. and D. Prior and Son had also small well arranged exhibits, showing numerous up-to-date kinds, the latter firm have some fine forms of polyantha roses, such as Elsie Poulsen.

Herbaceous and hardy plants formed the main bulk of the Show and these were ably displayed by many firms. Phloxes, with their vivid tints, were in evidence in an exhibit by Messrs. John Waterer. This exhibit was somewhat crowded, but a few varieties are worthy of mention, such as General van Heutsz (rose-salmon flushed with blue at base of petals), Antonin Mercie (bluey-purple with white centre). Chrysanthemum max. Phyllis Smith looked reliable. Messrs. B. Ladhams had a general collection of herbaceous plants with Lavatera Olbia rosea predominant. Mr. H. J. Jones showed a bed of herbaceous phloxes interspersed with Thalictrum dipterocarpum. Messrs. H. Hemsley produced the result of six year's work on Sidalceas, showing the many coloured strains which have been obtained by breeding. Mr. W. Wells, Junr., M. Prichard and Sons, Fred. G. Wood and the Chalk Hill Nurseries collections contained hardy and herbaceous plants, such as lupins, phloxes, Aconitum bicolor, delphiniums, while the last-named firm also had a fine collection of poppies.

In Messrs. Amos Perry's collection of hardy plants Chrysanthemum Icecap was outstanding among the many yellows of coreopsis.

Mr. C. H. Herbert showed Dianthus Herbertii, including such sorts as Fire King, Mrs. Giffard Woolley, Bridesmaid and Gertrude.

A special word of commendation is due to Isaac House and Sons for their show of new hardy perennial scabiosas. These were of good quality and showed a grading in colour from Isaac House (a deep blue), Constancy (of a medium depth of blue) to Edith (pale blue).

Mr. Thomas Carlile, Mr. G. Reuthe and Messrs. Tucker had hardy herbaceous and rock plants exhibited to advantage, while Messrs. L. R. Russell, Limited, showed clematises and greenhouse plants.

Carnations were once more in the able hands of Messrs. Allwood Bros., C. Engelmann, Lowe and Gibson and John R. Crowhurst—the latter showing healthy cut blooms which were all grown out of doors.

The fruit exhibits of Messrs. Geo. Bunyard, cherries, currants and gooseberries; Chivers and Sons, Limited, currants, raspberries and gooseberries; Laxton Bros., currants and gooseberries were up to the usual standard of excellence of these firms.

NEW AND RARE PLANTS.

ZINNIA DOBBIE'S GIANT DAHLIA-FLOWERED.—A good strain of this showy annual was on view. The flowers varied somewhat in colour, from pale pink to yellow and scarlet and crimson, and were of immense size. This strain should soon become popular. Award of merit. Shown by Messrs. Dobbie and Co., of Edinburgh.

PLAGIANTHUS LYALLII *var.* GLABRATA.—This is a shrub of the family Malvaceæ, which is hardy in favoured parts of this country. The large white five-petalled flowers lend an air of distinction to the plant, hanging as they do in axillary leafy panicles. The foliage is light green in colour, the leaves ovate and serrate in outline. It is decidedly graceful in habit and deserves to be recognised for its own worth. Award of merit. Shown by Messrs. R. Veitch and Son, Exeter.

LAGERSTRŒMIA INDICA.—This is a glabrous smooth and brown-barked shrub, with rather small ovoid sessile leaves. The flowers, borne in an open panicle are bright rosy pink in colour, but in some cases show a tinge of purple or white. The bloom in summer is profuse, as the specimen exhibited showed to advantage. It well repays the cultivator who spends time over it. It can be propagated easily from seed or cuttings. Award of merit. Shown by The Director, University Botanic Gardens, Cambridge.

BORDER CARNATION SIR CHARLES SEELEY.—Fine shapely blooms of good quality and colour. It is of a scarlet tint, with a good depth of colour. The petals have a rich velvety appearance and they do not show splitting. The blooms are gracefully poised on slender, wiry stems, setting them off to advantage when placed in a vase. Award of merit. Shown by Mr. E. C. Goble.

HEMEROCALLIS HYBRIDA LADY HESKETH.—A very fine form indeed of this genus so much prized in open planting. The specimens exhibited were tall and graceful, with tall scapes sometimes branching so that the inflorescence becomes semi-paniculate. The flowers are large and lily-like and a good sulphur yellow in colour. The perianth might be described as bell-shaped with an expanding cylindrical tube. The stamens are delicately set on slender filaments. Leaves are basal, long and linear. It shows an improvement in shape on one of its parents, viz. H. citrine. The parentage is H. Thunbergii × H. citrine. Award of merit. Shown by Messrs. A. Perry, Enfield.

ORCHIDS

MILTONIA CONSTANCE *var.* REGINA (vexillaria × Isabel Sander).—A great improvement on the well known M. vexillaria, the colour being deep rose, and with ray-like markings around the crest at the base of the labellum. Award of merit. Shown by Mr. H. T. Pitt.

MILTONIA PHALÆNOPSIS.—A finely grown plant with sixteen flowers was shown. It is a native of Colombia. Cultural commendation to Mr. Thurgood, gardener to Mr. H. T. Pitt.

PROMENÆA XANTHINA.—An excellent plant was shown with over seventy flowers of citron-yellow colour. This species is also known in gardens as P. citrina, and by some authorities the genus promenæa is regarded as a section of the genus zygopetalum. This orchid is generally given a place in the intermediate house, but Mr. E. R. Ashton's specimen has been cultivated in the cool house, along with the odontoglossums, and this treatment is evidently beneficial to successful results. Cultural Commendation to Mr. Kent, gardener to Mr. E. R. Ashton.

FLORISTS' CARNATIONS AT VINCENT SQUARE.

THE National Carnation and Picotee Society, which seeks in a measure to perpetuate the old florists' carnation, held its Annual Show at Vincent Square, Westminster, on July 22nd last. But, with flowers, as in manners and dress, fashion changes and the old order giveth place to the new. No longer does the carnation fancier show his blooms, mathematically placed at regular intervals on show boards, with a paper collar around the neck. Until quite recently the Society had a few classes at the beginning of the schedule for bizarres and flakes shown in this manner, but now the remaining four classes are relegated to a minor position and prizes won in them "do not count points for cups or medals." But there were no exhibits in these classes, so it would seem that the day of the real florists' carnation is practically over.

It may be interesting to point out that the self-coloured carnation now so popular was once "accounted a great defect." Then there were three classes of carnation—the flake, the bizarre and the picotee, but long since we have come to consider the picotee to be "like the pink, a distinct species," and while preserving "the right spelling, give it an English pronunciation."

But to our present day floral taste these "defective" self coloured carnations made a very effective display and it was pleasant to note, as was the case at the recent Sweet Pea Show, that fragrance is more frequent in the flowers than of recent years.

For the first time, probably, over a very long period, the name of Mr. James Douglas did not appear on the exhibitors' cards in the open division where the chief prize winners were Messrs. Lowe and Gibson, who staged exceedingly good blooms. Their prize-winning carnations were Yvonne Thomas, Bookham Rose and Dora Blick, among the selfs; Jenny Murray and St. C. Amos, and of the fancies other than yellow or buff-green, Mrs. E. Charrington.

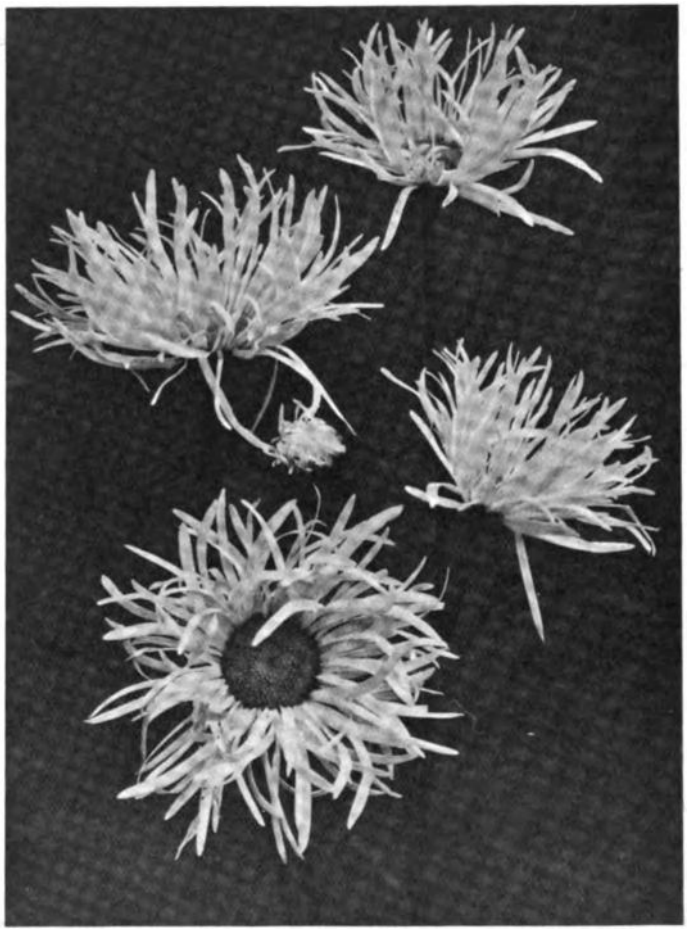
Mr. R. Morton, Woodside Park, won the first prize in the class for yellow or buff ground fancies with very good vases of Kelso, Highland Mary and Lieutenant Shackleton.

In the principal amateurs' division Miss Shiffner, Lewes, won nearly all the prizes and so holds the Martin Smith Memorial Cup for the year. Miss Shiffner had lovely vases of Viceroy, Kelso, Rose Clove and Mrs. A. Brotherston. The last named a heavily flaked crimson was the premier clove-scented bloom in the Show. Mr. E. Charrington had the three best vases of fancies, other than yellow ground, and Mrs. E. Charrington, the premier fancy. In the colour classes Miss Shiffner was the only first prize winner and her varieties were Purity (white), Border Yellow, Elizabeth Shiffner (terra cotta), Jean Douglas (scarlet), Mrs. G. Marshall (maroon), Bookham Rose and The Grey Douglas.

The Edmund Charrington Cup was won by Mr. E. H. Painter, Brentford, who in Eclipse had the premier light-edged yellow ground picotee. Mr. H. A. Knapton, Orpington, had the best picotees and yellow ground fancies, while Mr. S. Williams, Chipstead, was first with selfs and white ground fancies.

The Cartwright Challenge Cup, in the small growers' division, was won by Mr. F. H. Seymour, Finchley, who had praiseworthy blooms.

In the seedling classes Mr. G. D. Murray had two very beautiful varieties. Joan Wardale, an intense crimson maroon self, and Myrtle Pettigrew, a very uncommon fancy which may be described as greyish-heliotrope, lightly flaked with scarlet. Both varieties were of large size, perfect form and deliciously fragrant.



CHRYSANTHEMUM "ICE CAP."

HARDY BRITISH FERNS

THE FERN HAS A CHARM AND GRACEFULNESS ALL ITS OWN AND IS EXCELLENT FOR DECORATIVE PURPOSES, ESPECIALLY IN THE ROCKERY, WHERE IT LENDS A CERTAIN DISTINCTION TO THE SURROUNDINGS.

THE enquiries for plants to grow in certain places, such as dark, shady, wet or dry positions, are so numerous that I fear it may seem presumptuous on my part to take up so much space with "Hardy British Ferns." However, it must be admitted there are many and numerous nooks and corners by the side of houses and mansions, a porch or terrace, or under trees on a lawn, which are more or less shut out from direct sunlight, and where many flowering plants fail to bloom, or even give a small return for the labour and time allotted to them. These hardy British ferns, with such luxuriant greenery and freshness, take their place in situations where such plants as peonies, delphiniums, Michaelmas daisies, beardless irises, phloxes, etc., fail to grow. Yet, the hardy fernery need not be flowerless, as such spring flowering plants as daffodils, wood hyacinths (Scilla nutans), hardy cyclamen, the Lenten roses (Helleborus orientalis), also the American Dog-tooth violets (Erythronium) and wood anemones (Anemone nemorosa), if judiciously planted, will produce quite a display of flowers during the spring months.

A BEAUTIFUL CRESTED VARIETY OF THE HART'S TONGUE FERN, SCOLOPENDRIUM VULGARE GOLDEN QUEEN.

At the recent Chelsea exhibition many must have noticed the cool and restful appearance of the foundation bank of British ferns in the group of Iris barbata shown by Mr. Perry. The ferns imparted a peculiarly fascinating and graceful ground-line base to the iris that must have appealed to all who saw them. This, by the way, illustrates their usefulness as exhibition plants, but it is not altogether as exhibition plants that I attribute their especial merits.

In tropical countries ferns are much more in evidence for garden decoration than is general in our British gardens. In these tropical gardens one frequently meets tree ferns and other graceful and beautiful species. Associated with palms, such as lantana, cocos, kentias, etc., planted in graceful irregular groups, they give the surroundings a most charming effect; but they are quickly disfigured in our changeable climate, and if planted as summer sub-tropical bedding, must necessarily be protected from cold winds and frosts.

There are endless varieties of hardy ferns that may be planted with impunity in our gardens, and which are equally effective and as graceful as many of the tropical varieties, and the great advantage in planting British ferns is that they are hardy, and withstand our coldest winters. I do not pretend to give a botanical description of the genera, but only a short list of the outstanding and most decorative varieties.

In the soft prickly shield fern (Polystichum angulare), there is quite a host of varieties, varying in height from dwarf congested forms of a few inches, to tall, erect, spreading fronds with the most characteristic differences, and particularly suitable for planting in shady nooks and ravines, or wooded banks and slopes. P. angulare divisilobum plumosum densum erectum, is fully described by the name, viz., erect, dense and feathered divided lobes, of a delicate soft green.

P. a. d. p. d. Perry No. 1 is the most beautiful and most graceful, and nearest approach to vegetable mosaic tracery, the broad handsome fronds are pale green, with gold-coloured sheen at the edges of the pinnules, which overlap each other in the most graceful manner possible.

P. a. d. p. d. robustum Perry has a strong, vigorous, robust habit, which renders it one of the most graceful and beautiful of all polystichums, with its massive fronds 3ft. and more in length, the base of which is frequently 10ins. to 12ins. wide, with neat and finely divided pinnæ, and elegantly plumose.

P. a. d. p. d. superbum is one of the most distinct, and closely resembles in its construction the "Todea superba" or a plumose form of nephrolepis, in the density of its fronds. The young fronds are a delicate pale green, gradually turning a darker green with age, remaining in this condition until quite late in the season. There is quite a number of the "divisilobum" type and all are well adapted for pot culture. In the dwarf congested forms, with pinnæ and pinnules closely set and overlapping, are P. a. congestum minus, and the variety cristatum, with prettily crested fronds, also P. angulare parvissimum, a dwarf with very closely set pinnules, giving the plant, which is not more than a few inches high, a very neat appearance. The varieties of polystichum are so numerous that it would require too great a space to describe even a fair selection, but the above are all outstanding varieties and may be recommended as only a few of the best.

The lastreas are another large and interesting genus and include many distinct and very beautiful also decorative forms, highly adapted for various situations; some diminutive and admirably suited for the chinks of rockeries, while many develop into the most beautiful specimens imaginable, growing several feet tall when established. The general compost should consist of good fibrous loam, leaf-mould or peat, and sufficient coarse sand to admit of a free percolation of moisture.

L. dilatata (the broad Buckler fern), is a very robust species and under favourable conditions quickly develops into a handsome specimen. The outstanding varieties are: L. d. crispata, with bold massive branched heads, a tall grower;

Digitized by Google

L. d. crispata cristata, beautifully crested; L. d. grandiceps, a very graceful and decorative fern, with heavy tasselled crests.

L. Filix-mas (the soft male fern) is a vigorous-growing plant, with good habit, very accommodating as regards soil and situation, and frequently found luxuriating in town and London gardens, producing its fronds in stout tufts from a central crown. The broad and lance-shaped fronds are of a refreshingly verdant green during the summer. A few of the most outstanding are: L. F.-m. Bollandæ, L. F.-m. crispa Barnesii, L. F.-m. cristata Barnesii, L. F.-m. c. Martindale, L. F.-m. foliosa, with gracefully recurving fronds, and L. F.-m. grandiceps, prettily crested and with heavily tasselled heads.

L. pseudo-mas (the hard male ferns), are most decorative on account of their stately, robust habit and duration, producing as they do large fronds of a distinct leathery character until well into the second season, each year's fronds replacing the previous year's growth, quickly forming magnificent specimens when planted in a shady, moist position in a light alluvial soil. Some of the best are: L. p.-m. angustata cristata, long, strap-shaped fronds, prettily and evenly crested, very effective and distinct. L. p.-m. crispa cristata, L. p.-m. c. c. angustata, L. p.-m. cristata, very heavily crested, a most handsome fern; L. p.-m. splendens, a very tall, handsome fern; L. p.-m. ramo-cristata, exceedingly ornamental, forming a compact bush and prettily crested.

Osmunda regalis (the royal fern), is the most dignified and stately of our indigenous ferns, and cannot be overlooked. It well merits its regal honours. It is found in the boggy and marshy woods by the Devonshire lakes and Killarney streams and also in various parts of England luxuriating in majestic splendour. It has a large, massive rhizome, bearing fresh, green fronds of leathery texture, and in favoured localities may often reach the towering height of 6ft. to 10ft. It is anomalously called the "flowering fern," on account of the sporangia (or spore cases) formed in terminal brown panicles above the fronds and which are strikingly obvious at first sight, adding considerably to the majestic growth and stature of the plant. The following are worthy of a position for planting on the shady side of water-lily ponds or streams, lakes or anywhere where their fibrous roots have the benefit of the spongy, peaty soil:

O. regalis, the well known royal fern; O. r. cristata, a very beautiful crested form, with large spreading fronds.

Scolopendrium vulgare (the hart's-tongue fern).—Few genera are so varied in construction as the hart's-tongue ferns. Their flaccid, bright green leaves, with cordate base, are to be found in all the most fantastic forms imaginable, from the strap shape of the typical species, to the most beautifully crested and waved forms. All are perfectly hardy and evergreen, revelling in limestone rocks, cliffs, ravines or the shady parts of lakes or streams, hedgerows or leafy woods. If planted in light, peaty soil, or leaf-mould, and given good drainage, a luxuriant growth is assured. It must suffice to mention but a few outstanding varieties, as they are endless:

S. v. crispum nobile, of recent introduction, the large and deeply frilled fronds are extremely beautiful, 2ft. or more in length and 5ins. broad at the base, a most handsome pot plant. S. v. crispum Robinson's var.; S. v. fimbriatum; S. v. grande; S. v. peraferens; S. v. robustum; S. v. plumosum, are all extremely decorative.

Other interesting ferns and well adapted for the rockery are the Polypodium Phegopteris (the beech fern); does well where moisture and shade prevail. P. Dryopteris (the oak fern), delights in woods and dry, shady nooks in the rockery; P. calcareum (the limestone polypody), produces masses of lovely foliage, and delights in limestone rocks and shade.

P. vulgare is extremely pretty in almost any position in shady or practically shaded rockeries, etc., and embraces some of the most exquisite evergreen species and varieties in hardy ferns. The following should be in all collections: P. v. Bideford variety; P. v. cambricum (the Welsh polypody); P. v. cambricum Barrowi; P. v. grandiceps, P. v. Forster's variety; P. v. Fox's variety, each beautifully crested, and P. v. ramosum.

Blechnum Spicant (the hard fern), is most charming for pot culture, and for shady damp situations in the rockery in a peat and leafy soil. B. S. cristatum and B. S. trinervum coronans are most beautiful.

Adiantum Capillus-veneris is one of the most popular ferns for planting in the crevices in the rockery, producing neat tufts

A DECORATIVE FERN FOR POT CULTURE, SCOLOPENDRIUM V. C. PLUMOSUM.

of handsome maidenhair fern-like foliage. A. C.-v. imbricatum and A. C.-v. magnificum are exceedingly handsome, comparing favourably with the well known greenhouse fern, A. Farleyense.

Asplenium Ruta-muraria (the wall rue), quickly becomes established on old walls and in niches in the rockery in old mortar rubbish and leaf mould. A. Trichomanes, the common spleenwort, and A. T. cristatum should be similarly treated and will create a glorious effect. A. viride (the green spleenwort) delights in a more moist situation.

Athyrium Filix-fœmina (the lady fern) is a very important, interesting and varied group of deciduous ferns, consisting of many curious and fascinating forms, from the most diminutive to several feet high. To give an accurate description would be too complex, and a most difficult task. The most important feature of this group is, that they lend themselves to almost any kind of soil and position, but like other members of the family, require shade and moisture, with a free, open, light, leafy soil to ensure their successful cultivation The raising of ferns from spores is very interesting and will be dealt with later.

INSECTICIDES

THE NECESSITY OF YOUR GARDEN IS TO BE KEPT FREE FROM PESTS.

AT this time of the year, when everyone regards their garden with pride, be it one which runs into many acres or one which can be measured in terms of square feet, an unwelcome visitor in the form of the insect is always to be found near by and may, if suitable conditions prevail, multiply rapidly and become a serious menace to the grower, whether of flowers or fruit. The gardener regards with great misgiving the visits of these marauders, and begins to look around for the necessary materials to entrap the unwary and keep his flowers free from their attacks and hence maintain a good crop of fruit, flowers and vegetables—which, in the end, is both economical and the result gratifying to the onlooker.

One could write at great length on the many and varied kinds of insecticides which are at present on the market, but it would serve no useful purpose to the amateur, at least, to be faced with more or less of a catalogue of these sorts and hence be in a maze when he is confronted with a particular problem. I think, rather, it might be better to give a general survey of the various washes and discuss their uses, their advantages and disadvantages, so that the reader can choose for himself the particular one which will meet his own case.

Insecticides generally take the form of poisons, washes or gases. The essential requirements in these substances are, primarily, safety to the plant and also to animals which may, perchance, roam in the garden; secondly, efficient killing power combined with cheapness and ease of application. To a large extent, the nature of the insecticide used is governed by the nature and growth of the plant, and also by the nature of the insect, and the method whereby it obtains its food. They may, then, be classed into those which kill by poisoning the insect in application with food, those that kill by contact with the insect's body, and fumes of gases, used in fumigation, especially in greenhouses. The poisons are effective against the biting and chewing species, while the contact insecticides are used against the sucking kinds.

The most widely used substance for poisoning insects is arsenic in its various compounds. One should be careful in that only compounds insoluble in water should be used, as soluble arsenic is injurious to the leaves. There are quite a number of arsenical sprays, the most important of which are (1) Paris Green, which contains a high percentage of copper and arsenic; this has been an important insecticide in orchards for many years, but has now been replaced by others, such as lead arsenate. Its poisonous nature stands in the way of its universal use, as it scorches the leaves, and thus there is a certain risk to the plant. It can generally be bought in three forms: (1) lump, (2) powdered and (3) paste. The last-named, I consider, is the best, as it is easily mixed with water or Bordeaux mixture. The fluid should be constantly agitated. The average strength is about an ounce to 10 gallons of water or Bordeaux mixture. It should not be used with lime-sulphur wash as used for summer spraying. Arsenate of lead has now come into great favour. It has a decided advantage in that it is not so dangerous to human beings or to the plants. It adheres much better to the leaves and can be employed at considerably greater strengths without injuring the foliage. By sweetening the substance it is often more readily partaken of by insects. Some books indicate that it may be freely used, but that is hardly correct, as it should be used under control. It can also be bought in paste form. It can be made by dissolving arsenate of soda by itself in water, and also lead acetate, and then mix the two. It can be employed in any strength desired, depending on the nature of the insect and whether or not the foliage is susceptible to injury. About 7 oz. to every 10 gallons of water will doubtless serve for ordinary purposes.

A preventive wash may often be applied with beneficial results. An example of this is lead chromate, which can be used for spraying on the leaves of fruit trees as soon as the foliage is out. The wash remains on the leaves during the season and they are rendered distasteful to caterpillars, sawflies, etc. Dissolve 1lb. of lead acetate or nitrate in the sprayer; then dissolve 2lb. of potassium bichromate and add to the sprayer. In using it the mixture should be kept well stirred.

The most important contact insecticides are soaps, sulphur compounds, and oily or resinous emulsions.

Paraffin and nicotine emulsion sprays are useful, especially when combating sucking insects and also certain caterpillars. About 2olb. of soft soap should be dissolved in 5–10 gallons of boiling water. Emulsify the paraffin in the hot soap solution by taking the paraffin up a syringeful at a time and squirting it violently into the soap solution. Then add the nicotine (½lb.) and dilute to 100 gallons. A difficulty often met with when combining a lead arsenate and a spray for sucking insects is the difference in the application of the two sprays. For a sucker, spray with force and in abundance; but when using an arsenate the spray should be fine and misty, so as to adhere to the foliage. What is required is as uniform a spray as possible.

Paraffin emulsion can be used alone by dissolving soft soap in water and, while still boiling, pour in the paraffin. Churn very thoroughly. For use, dilute 1 part of the emulsion with 10–50 times the bulk of water, according to the tenderness or hardiness of the leaf.

Tobacco is one of the most useful of insecticides owing to the alkaloid nicotine. The strength varies much, and it would be well to have a standardised nicotine spray on the market. The nicotine generally used is not pure, but sulphate of nicotine. It is an excellent contact spray, and can also prevail against some biting insects. Pyrethrum powder is also to be found on the market in three brands. It can either be used in solution or dry.

In fumigation one of the commonest fumigants is bisulphide of carbon. It is a heavy liquid which has ready volatile properties. It is heavier than air, and the material to be fumigated must always be lower than the fumigant. The drawbacks are: (1) Vapour is poisonous if one remains in it for a long time; it is also explosive, and no naked light must be brought near. It can also be used for reaching soil insects. Liquid should be put in with a syringe and should not be allowed to touch the roots. It is somewhat expensive.

Sulphur is excellent for pests in houses, but, unfortunately, the fumes injure the plants. It affects injuriously the germination power of the seeds. To a certain extent sulphur has a bleaching action. Tobacco is useful as a fumigant, but if used as such the plants may show spotting. The most dangerous—but, nevertheless, perhaps the most useful—is hydrocyanic acid. Fumigation should only be carried out by an expert. Recently potassium cyanide has been put on the market in metal plates. The advantage is that the operator has time to get away before the metal is eaten through.

Many poisons can be employed, such as arsine—which should be used under control, as it is injurious to the plant; carbon monoxide, which should be used in fairly high concentration to be really efficient, and then it becomes dangerous.

Winter washes should be given during the dormant season, but should not be carried out too often, as it is bad for the tree. A caustic wash can be used at any time, and the strength of the solution is not of much account. The best form of soda is powdered soda 98 per cent. purity. Lime-sulphur washes are finding great favour these days and are exceedingly useful for protection of fruit trees. It should be extensively used against scale insects. A stock of this wash can easily be made up, and for use this should be diluted with varying proportions of water according to the season of the year. The stock should be kept in an air-tight barrel. The purpose of caustic washes is to clear and clean the trees of injurious growths, such as moss and lichens, which act as a shelter for hibernating insects.

Where insects may escape the winter wash a spring wash is necessary and is often more important. Summer and autumn washes should also be given throughout the year. These washes can be obtained made up by the many firms engaged in this trade, and no trouble should be experienced in procuring them, or in their application.

Digitized by Google

There are many proprietary brands, such as white fly compounds, sold by Messrs. Abol, Limited; Niquas, by Messrs. Corry and Co.; quassia extract (a bitter principle), etc., which one ought to mention and which can easily be obtained in the market; but the few dealt with will serve to show the range and scope of the various brands. Many well known firms such as Messrs. E. Cook and Co., Bow, and G. H. Richards, specialise in the manufacture of up-to-date insecticides suitable to meet particular cases, and their respective specialities are worthy of notice. The grower cannot afford to neglect the ravages of the marauders, otherwise a serious loss will be the inevitable result, and a few shillings well spent may save one pounds in the near future, and if anyone needs to look ahead it is the gardener and the fruit grower. G. C. TAYLOR.

BOTANICAL WIZARDRY: OR PLANT PROPAGATION AT EDINBURGH

IT is now many, many years since the name of the Plant Propagating School at the Royal Botanic Garden, Edinburgh, has been known over the civilised world; indeed, one is tempted to go farther back—it was an Adam who propagated Cytisus Adami; it was an Adam who projected a lantern slide upon a screen at Edinburgh on July 17th, to illustrate how a fig-leaf detached from the parent plant could, under certain conditions of temperature and moisture, produce root and shoot and develop a young plant. Surely, then, we do not need to emphasise the great antiquity of the art and craft of the propagation of plants by man.

During the last twenty years, however, this craft has gradually approached the status of a science in this northern school. At least one text-book contained the statement that the pine could not be propagated from cuttings—that was sufficient for the head propagator at Edinburgh, Mr. L. B. Stewart. Within three months of this statement being made, he had a 70 per cent. success with these "impossible" cuttings. In another case, Erinacea pungens, commercial propagation takes fifteen months; but, by means of the sun-frame, Stewart has produced 700 cuttings within two months, obtaining successful rooting in twenty-one days. Many other similar successes might be recorded, but the master has gathered together a group of University botanical workers whose results will shortly be given in detail and it is the purpose of this note to report briefly the first conference on plant propagation to be held in Edinburgh.

On July 17th and 18th the Botanical Society of Edinburgh devoted the tenth ordinary meeting of its eighty-eighth session to this subject and provided a very interesting and most instructive programme. The first morning was occupied with a demonstration of vegetative propagation by means of stem cuttings, copiously illustrated by some 212 actual specimens and by about 200 photographs. In the afternoon the President, Professor W. Wright Smith, explained that the idea of the conference was to give healthy publicity to such results as were certain and to stimulate others, if possible, to assist in dealing with the complex problems involved. Then followed three papers by Miss E. Philip Smith, Dr. R. J. D. Graham and Mr. L. B. Stewart, through which ran the twin golden threads of well regulated team work and that keen interest in the mechanism of the living plant which is our only hope of learning the truth about propagation.

The second morning was occupied with a demonstration of vegetative propagation from leaf and root, again illustrated by numerous specimens. Then followed a paper by Dr. Graham on "Propagation by Bulb Scales," and one by Mr. Stewart on "Root Cuttings." During both afternoon sessions discussions were lively, and many interesting points were brought out in response to queries from the audience.

Although clematis will not normally root at the nodes (only from the internodes), Miss Philip Smith demonstrated very clearly how, by blanching the stem for about three weeks while it is still on the plant, nodal cuttings can be induced to strike. This rooting is associated with a softening of the tissues

GENERAL VIEW OF THE LABORATORY SHOWING THE MANY EXHIBITS.

and a disappearance of stored starch as the result of covering the stem to be cut with black paper or even with Indian ink.

In Dr. Graham's work on propagation from leaves a number of interesting generalities became apparent. In propagation from the leaf the adult form is produced if the whole leaf be allowed to develop one plantlet; whereas, if the midrib be cut and the leaf thus persuaded to develop several plantlets, a more juvenile type of plant is produced. With normal dicotyledonous leaves the roots appear first and are followed by buds at an interval which appears to depend on the period during which the parent leaf can remain alive. Thus the leaves of Coleus Blumei var. develop roots readily, but only two out of sixty rooted leaves were found to produce shoot-buds. Melastomaceæ and Gesneraceæ were mentioned as being readily propagated from the leaves. Most species of hoya are likewise easily propagated in this fashion, with the exception of Hoya carnosa, where

TWO SPECIMENS OF GARDENIA.
The short squat one is a branch cutting taken from the taller plant near the base, and is only one year younger.

the leaf-base has a large amount of hard tissue.

On the other hand, the development of the shoot-bud comes first in the case of monocotyledons and succulent dicotyledons. An exception occurs among the former in Zamioculcas Loddigesii, which produces roots first and then a tuberous structure from which ultimately the shoot-bud arises as the parent leaf dies off.

In propagation from bulb-scales the plant is even more vigorously treated. The scales as a rule are left in the light on a dry bench for three to five weeks, and at the end of that period they develop shoot-buds on the inner surface, either from the new tissue of the callus, as in ornithogalum species, or from the old parenchymatous tissue of the scale above the injury, as in hæmanthus, or from both regions, as in drimia. Interesting cases of buds occurring normally on the back or exterior surface of bulb scales were given; in ornithogalum species these arise in two opposite rows on the line of junction of the leaves. Scilla and hyacinth were also mentioned as having been known to give rise to adventitious buds on badly injured scale-leaves.

Mr. L. B. Stewart dealt in particular with branch cuttings from plants with whorled horizontal branching and demonstrated how such cuttings remain branches in form, not developing a vertical axis and, in the case of gardenia species, producing flowers every year after being struck, although the parent plant does not flower until over ten or twelve years old. This curious persistence of branch form is accompanied by the even more curious phenomenon of the production of vertical normal non-flowering shoots by buds from the roots of the branch cuttings. These phenomena are general in all cases of plants, such as araucaria, other conifers, and Napoleona, which have whorled horizontal branching. Regeneration of a leader, when the primary leader is injured or lost, takes place, according to this authority, by the development of superficial buds as an injury response.

Mr. Stewart, in response to a query, delivered a lecturette on the various types of stem cuttings, distinguishing between the herbaceous or chrysanthemum type, which dies down to ground level and produces new shoots; the woody type, where the original piece of stem persists; and a third type, which produces a more or less tuberous rootstock from which shoots are thrown up annually.

Dealing on Friday afternoon with root-cuttings, he demonstrated how true roots develop buds only on the upper side as a rule, while dormant axillary buds develop on rhizomes on any side of a horizontal piece. This obvious distinction is confirmed by anatomical investigation. As in the case of dicotyledonous leaves, it has been found that the smaller the piece of root used for propagation the more juvenile the form of the shoot produced. Equal weights of acanthus root were found to develop exactly the same type of shoot from whichever part of the root they were taken.

Digitized by Google

During the discussions it became evident that, while special cases require special treatment, a general guide to successful propagation by means of stems in particular may be found in the taking of the cuttings from twigs which are neither so soft that they rot away quickly in a moist medium or so hard that the primordia encounter mechanical difficulties. This condition is most frequently found when the twigs have completed their seasonal elongation and before the tissues have become thoroughly lignified. "Half-made wood strikes best." Finally, the work as a whole tends to show that, in the hands of a really efficient plant propagator and under certain conditions which vary from species to species, practically any part of any plant is capable of reproducing the whole.

The general impression gathered by a visitor may be compared with the early stages of the blooming of a century plant, when the concealing sheaths are being thrown off and the team work of the whole plant is bringing into view the superb mass of bloom which is the natural result of years of quiet storage and accumulation of a very large mass of reserve material. We shall undoubtedly hear much more of the Edinburgh School of Plant Propagation, and the publication of results will be awaited eagerly by all those interested in the vegetative propagation of plants. (Prof.) JAMES SMALL.

CORRESPONDENCE

CONCERNING A FUCHSIA PLANT.

SIR,—About Christmas time a friend interested in gardening matters gave me a fuchsia in a 4½in. pot. He did not know the variety, but said the parent plant from which he had obtained it was growing outside in a Cornish garden. Towards the end of January the plant began to show for bloom, and it continued in flower for eight to ten weeks. Then followed a fortnight's rest, during which period I took off and inserted half a dozen cuttings, thinking there would be no more flowering. To my pleasant surprise, however, the plant again started blooming, and it is still doing so now, mid-June! The cuttings are rooted, though not yet potted, and they, too, are showing many buds. Is not this record of profuse and continuous flowering most unusual for Fuchsia triphylla?—which species, I understand from the Director of Kew to whom I sent blooms, is the plant here under notice. It would be interesting and valuable to hear from anyone who has grown this plant for greenhouse decoration whether it is customary for it to be so free and long-flowering when so grown.

I have never grown this fuchsia for greenhouse work before. Has any reader of THE GARDEN? Its genuine decorative worth is beyond question. Practically every shoot bears flowers, the pendulous clusters varying in size according to the strength of the growth. Should it be the nature of Fuchsia triphylla so to behave, surely it deserves greater recognition, for, in my opinion, it is questionable if another plant can be named to surpass it for beauty and usefulness under glass in winter and spring.

The flowers are about 2ins. long and of a salmon-scarlet shade, while the base of the leaves, the midrib and veins are a purplish tone.

I believe there are in commerce some splendid hybrids of F. triphylla. Is it possible my plant may be one of such?—C. TURNER, *Ampthill*.

ANOTHER APPRECIATION.

SIR,—I am an amateur in the kindergarten class of gardening, having possessed a real garden for some three years. I took in THE GARDEN at the outset of my career, and though at first, I must confess, it served only to illume the depth of my ignorance, I would like here and now to say how very much it has helped me, and to add mine to the many letters of appreciation I know you have received. Although about 90 per cent. of the matter contained in the articles is still beyond my depth, I can find a great deal of pleasure in my weekly pursuit of this most illusive knowledge—and oh! the thrill of joy in discovering, in reading the record of someone else's failures, that one has, so to speak, spotted a winner on one's own! I made myself a ranunculus bed with all the dash and daring of a kindergartenite and read in the following week's issue of THE GARDEN one of Mr. Jacob's delightful articles on bulbs. The reverend gentleman said frankly that with the Ranunculus he had found a great deal of difficulty. I trembled guiltily. How dared I rush in where angels feared to tread? How dared I even hope that the pretty things would do for me what they had persistently refused to do for Mr. Jacob? Only the kindergartenite can imagine my unhallowed joy when my ranunculus (or is it "i"?) came up—rows of dainty frilly-petticoated ladies who filled my heart with delight. The experience has given me a rather fearsome confidence, not in myself, but in my luck. "Remember the ranunculus bed," I say to Wisdom when she bids me hesitate. Needless to say there are many sad little graves in my garden, and sometimes the weight of my concealed crimes lies heavily on my conscience. One success, however, wipes out a whole season's failure from a conscience kept well in hand.

A CURIOUS PHENOMENON IN MIGNONETTE.

(*a*) Flowers protruding from ovary, which is open at the top. (*b*) Ovary cut open longitudinally, showing the flowers closely packed together.

Three changes of gardeners in my short garden life have proved themselves to be adversities that also have their "sweet uses." I am rapidly losing all fear of the species. I am wiser now, and no longer quote THE GARDEN to my man. I follow the lead of an old schoolmistress of my youth, who used to say with quiet dignity when her methods were questioned, "This is the method I have adopted," thereby silencing all argument.

Have I written too much? You have written so often lately asking readers (class unspecified), to write anything that may help or inspire fellow readers. I feel sure that the class of kindergartenites must be legion, and we need a whole lot of inspiring—one reason for my daring. A second reason, to give my thanks for the weekly page on "Simple Gardening." I love it chiefly because twice I have actually found myself doing the right thing at the right time. And last and best reason, because I have a friendly feeling towards everyone who writes to the garden—Mr. Jacob, the entertaining Mr. Elliott and all, and I would be of their company (oh! the impertinence of me!). Of course you could punish me by refusing to publish this, but you would not have the heart?—M. WILSON, A KINDERGARTENITE.

TIGRIDIAS.

SIR,—I should be pleased to hear of any of your readers who have had experience with tigridias, also any who have grown watsonias outdoors.—"FANHAM."

ABNORMALITY IN MIGNONETTE.

SIR,—I do not know if it is a common occurrence for mignonette, instead of producing seeds, to grow a small head of flowers growing out of what should be the ovary. I have some of Dobbie's Queen in pots, and this only appears on two plants and only on one or two ovaries. Those I have shown it to say they have never seen this happen before. —J. M. W., *Bristol*.

[This apparently is a case of where the plant is cutting out part of its vegetative life. As far as we are aware this failure is not at all a common occurrence in the case of flowering plants and we should be glad to receive any comments by our readers on this phenomenon.—ED.]

A TROPICAL GARDEN.

SIR,—I have taken THE GARDEN for a year now and it is a tremendous help. Although my garden is only about sixteen miles from the Equator, the altitude, 8,700ft., enables me to grow practically all the English herbaceous plants that it is possible to raise from seed. The ground selected for my borders is a good lightish loam, and quantities of leaf-mould are available from the forest, which almost encircles the garden. Half-hardy plants are hardy here, and amaryllis, crinums, bougainvillea and such-like flourish, though I do not encourage them, as they look out-of-place among delphiniums and honeysuckle.

I am writing to ask if you can give me any help in regard to the raspberries. I have had the canes for about three years now and have picked a very few fine-sized, good-flavoured fruits from them, but cannot grow fine tall canes because they seem to expend all their energies in making suckers, so that each new row I plant is presently a jungle of 18in. high weakly canes. I was told that this was caused by injury and disturbance to the roots, but this is evidently not so, as a new row planted last year in a well manured trench and left undisturbed but for a spraying and attention to tying has behaved in just the same manner. If you can tell me the cause of the trouble I shall be very grateful, as the small canes bear nothing but one bunch of fruit at the tip. There are quantities of wild blackberries which are most prolific and a wild raspberry of very lusty growth, making upstanding clumps of 5ft. and 6ft. They have the true pendulous raspberry flower, in size quite

Digitized by Google

three times as large as the English species, while the fruits are very large, soft and juicy, of a clear orange colour, but not very tasty.

I cannot obtain any local information about raspberries because I do not know anyone who has any. In fact, the newness of our country and the extraordinarily local conditions make things difficult, and personal experience is often the only guide to growing things at all. I was once told that no gooseberry had ever, or would ever, live and fruit here, but that was disproved last year, and I am trying to get new bushes.

Strawberries are badly infected with leaf-spot, which rapidly kills the plants of all except the alpine varieties. At 7,000ft. they grow well, but whenever I have brought new plants up here (this farm is on virgin land, uncultivated till we settled on it) they have quickly died off, and even from English imported seed the young plants have succumbed in their second year. Yet on top of one of the Ruwenzori Mountains, with the wind from the snow peaks whistling over them, they grow rampantly near a tiny bamboo shelter, untended and left to battle with wild grasses. I believe that Musandama Mountain, where I found them, is approximately 9,000ft. high, and the variety looks and tastes like Royal Sovereign, though what kind traveller left them behind him I do not know!

I have so far entirely failed to raise from seed rhododendrons, clematises or the herbaceous phloxes, though I have tried often in boxes under shelter and in a hot-bed. Bulbs suffer badly from heat and damp on the voyage, and take some time to recover, but this year I have Narcissi incomparabilis and Emperor, chionodoxas (the only ones in the country I am told) and a few weedy tulips. I am trying all bulbs from seed. Wild flowers are a help in suggesting what classes of plants should do well. We have a beautiful gladiolus (Mellori you named it in an article in your paper), tritomas (flame and yellow) in the marshes, small blue lobelias and giant ones 14ft. high, thalictrum and maidenhair fern, Royal Osmunda fern, long white sprays of sweet-scented parasitic orchids on the forest trees, a beautiful tree hypericum with golden blossoms larger than Moserianum, a type of laburnum with yellow flowers as large as the crab's-claw of Australia, two kinds of wild clematis (one like Traveller's Joy and one like montana), a type of bright pink crocus, two varieties of sisyrinchium or bluet, and a laurel with small green inflorescence. Also an iridescent blue-green aconite and other less striking flowers. From the Traveller's Joy and laurel I imagine that both clematises and rhododendrons ought to thrive if only I could get them started. Both plants when imported from South Africa have been dead on arrival.

Our pests are many, but we have no slugs, earwigs or American blight, and no rabbits (there are a few hares, but they are no trouble). However, turnip fly, moles, mice, birds, wireworms, buck, cut-worms and elephants are all a nuisance. The latter, which live in the forest close by can be counted on to do more damage in ten minutes than all the rest put together in a year! The buck eat the hearts out of the plants, but are fairly easily scared off by putting up string and netting and wire nooses.—J. R. BARRADELL, *Kenya Colony*.

[We believe the difficulty of obtaining strong plants of raspberries and good crops of fruit lies in the fact that the soil is too shallow and too poor for the cultivated variety. The ideal soil should be deep and moist. A hot, loose or sandy, shallow soil is the least suitable. The raspberry bears leaves profusely and transpiration from them is great. In poor, shallow soils extra surface mulches and top-dressings are needed to encourage the growth of canes strong enough to bear average crops. The surplus young canes should be pulled out while small to prevent exhaustion of the ones retained—in this case the strongest.—ED.]

CORNUS CONTROVERSA, OF VERY ELEGANT HABIT.

AN ORNAMENTAL TREE.

SIR,—The accompanying photograph is that of a fine plant of Cornus controversa at Headfort, Kells, County Meath. It has been in the collection for at least thirty years. The plant as carefully measured by me is 38ft. high, and has two stems from the base. It is in robust health and is one of the most ornamental plants flowering at present (June 25th) in the arboretum.

It cannot in any way be confused with C. alternifolia, as both in habit and size it is abundantly distinct.

It is flowering earlier than usual this year, and may be ranked as one of the most desirable of our smaller flowering trees. Its habit is upright, not too spreading and very graceful.

We are indebted to Mr. W. J. Bean for clearing up the rather confused synonymy of this plant (see "Trees and Shrubs Hardy in the British Isles," by W. J. Bean, Vol. I, page 387).—HEADFORT.

SAXIFRAGA CÆSIA.

SIR.—I enclose a photograph I have taken of Saxifraga cæsia growing on my moraine. The two larger clumps are plants I bought from a reliable nurseryman three years ago. The smaller tufts are plants which I collected near Mürren last summer. I am afraid the picture is too small to illustrate the point I wish to raise, namely, is there more than one variety of the plant? Because the bought plants have very minute rosettes growing very closely together and the flowers are rather small, whereas the collected plants have slightly larger rosettes, which are inclined to straggle on short stems above the level of the soil and the flowers are distinctly larger. In other ways, such as length of flower stem, colour and markings, the plants are identical.

WILD AND CULTIVATED FORMS OF SAXIFRAGA CÆSIA.

While on the subject of this saxifrage, can any of your readers tell me why it is classified among the Kabschias. When comparing it with the dwarf Aizoons, such as S. valdensis and S. baldensis, it has always seemed to me to be a nearer relation to them than to the Kabschias, chiefly in the structure of the rosette and the type of flower and stem, and not least in the time of flowering, for S. cæsia comes into flower at the end of June, just as the large group of Aizoons are finished, and several weeks after the Kabschias have usually finished flowering in April. I am quite aware that I am possibly treading on uncertain ground, and that I shall be told rather severely that my powers of observation need a little cultivation, but that is what I am asking for, if only the answer is convincing and also helpful to any other readers who may have been puzzled on the subject.—(DR.) H. STEWART WACHER.

A USEFUL GREENHOUSE PLANT.

SIR,—Will you please let me commend to your readers who like winter-blooming flowers Browallia speciosa major. It is easily raised from seed or cuttings, does quite well in an ordinary cool greenhouse, and is simply never out of bloom winter or summer. The bright mauve flowers are about the size of the periwinkle and much like it. The plants attain a height of 2ft. in 5in. pots; and when they become leggy, if cut back they will be in full bloom again in a week or two. Care should be taken to get the correct seed.—EDWARD HOLT EVANS.

NOTES FROM CONTRIBUTORS

THE SAFFRON CROCUS.

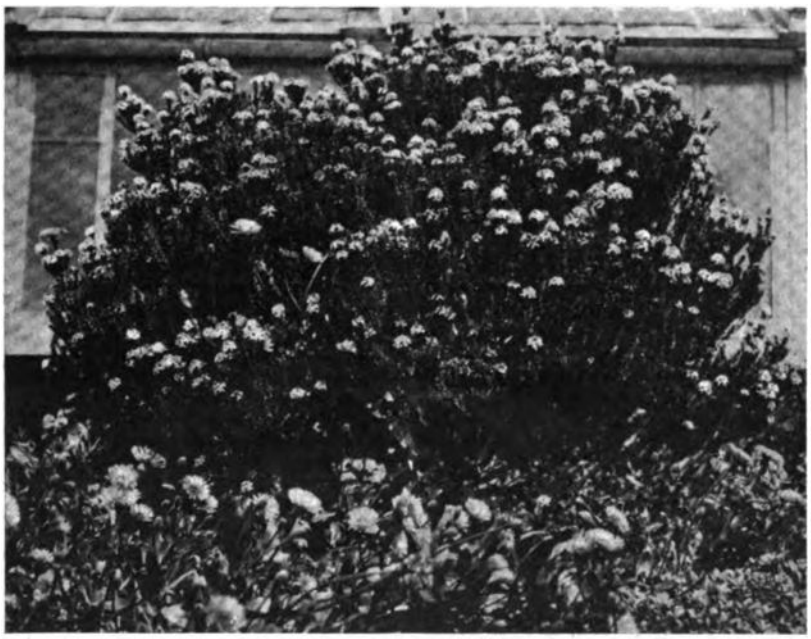
NOW that the time for the planting of autumnal-flowering crocuses to bloom this season is at hand, and lists are available from some dealers, it may be well to make a few remarks regarding the saffron crocus, Crocus sativus, and its shyness of flowering. It is a striking crocus with its purplish-lilac flowers and its brilliant scarlet stigmata. It is certainly a most attractive flower in every way, but its drawback is that when established it is a shy bloomer. It is a little difficult to understand why this is the case, as C. sativus was in past times largely cultivated in some parts of England for the production of the true saffron of commerce. This is now abandoned. It appears to be a crocus which requires a resting period greater than we can provide for it in the soil in most parts of this country, and that it would probably do better were it lifted when the leaves withered and rested until July or early August, when it might be replanted. In most cases it flowers fairly well when first procured, and this seems to bear out the idea here mentioned. In subsequent years it proves most disappointing, and the experience of the writer has been confirmed by many other cultivators who have tried this showy and attractive crocus. I am not anxious to deter anyone from trying it, and I may mention that I found the form known as C. sativus Cartwrightianus preferable on this account. C. sativus itself is a most interesting crocus and its literature is both extensive and most fascinating.—S. ARNOTT.

ROSE COLOURED VERONICAS.

THERE has been a recent addition to the number of dwarf herbaceous veronicas bearing rose-coloured flowers. This is V. rupestris rosea, which blooms during May and June. The species has had other names given it, such as V. prostrata and V. Teucrium dubia, the first two being old and appropriate to the habit of the plant. Whether or not V. rupestris rosea is an improvement upon the rich blue of the type is a moot point, but it is conspicuous and distinctly noticeable in a collection, and that is sufficient justification for including it among the occupants of the rock garden. A much older one is V. pectinata rosea, not very common in gardens at the present day. V. fruticulosa is even rarer, but very distinct in its way, since the stems are about a foot in height and perfectly erect. The most widely cultivated of these rose-coloured veronicas, and the tallest, is V. spicata rosea, which grows to an average height of 18ins., but may be taller occasionally. It is a very old one and may have arisen as a cross between the type and V. hybrida, or V. longifolia, for this is possible in gardens where the different species are brought close together.—HORTULANUS.

SHRUBS IN A READER'S GARDEN.

FOUR shrubs are now attractive in my garden. I send you a photograph of Olearia nummularifolia. It grows here 4ft. to 5ft. high and 5ft. to 6ft. wide—the composite in front is Urospermum Dalechampii. A second photograph is of Olearia insignis, the flowers and hoary white foliage of which are pretty. It grows very slowly and, like many woolly-leaved plants, requires slight protection in winter. Ozothamnus rosmarinifolius is a mass of white and well worth a place, and so is Stephanandra Tanakæ, not only for its present flowers, but for its rich autumn colouring. — SPENCER BICKHAM, *Ledbury*.



AN ATTRACTIVE GARDEN SHRUB, OLEARIA NUMMULARIFOLIA.

THE HOARY WHITE FOLIAGE OF OLEARIA INSIGNIS.

FLOWER LAWNS.

FOR those who cannot afford to pay for much labour and yet love to have their lawns in the trim, well kept condition which characterises British gardens, a lovely substitute for a grass lawn can be had by sowing flower seeds instead of grass ones. Messrs. Vilmorin sell a delectable mixture of dwarf flower seeds and ornamental grass aptly named Gazon du Paradis. When once this has been sown it can be left to its own charming devices, as it seeds itself abundantly. Gazon du Paradis is particularly effective if it replaces a grassy slope.

Another plan to save constant mowing is to dot a number of flowering plants in the grass. Bulbs of anemones, daffodils, ranunculus, Parisian hyacinths, etc., which are planted in the autumn can be interspersed with clumps of dwarf perennials such as the dwarf centaurea, mossy saxifrages, polyanthuses and double daisies. Annuals like poppies and cornflowers may be sown thinly here and there. Banks and slopes can be entirely planted with a variety of mossy saxifrages. When the beauty of their pink, white, yellow and red blossoms is over, their foliage makes a green carpet for the rest of the year. The French call these saxifrages "Gazon d'Espagne."

The most attractive and ambitious flower lawn is, however, the planted alpine meadow. In this case bulbs of all sorts are planted thickly in clumps or in broad stretches in colour schemes according to the fancy of the planter. Breadths of yellow crocuses, for instance, merging into a sea of gentian-blue scillas; a sweep of Poet's narcissi flanked by gorgeous plantations of French anemones of every hue.

Clumps of such herbaceous plants as are not out of their natural habitat in a meadow may be set among the bulbs. Giant marguerites, geums and delphiniums, for example, add to the interest of this flowery mead. From February to May annuals are sown broadcast to succeed the bulbs. These may be mixed in tall and dwarf varieties or sown in masses planned to give a certain effect. Californian poppies, scarlet, orange, yellow, pink and mauve, dainty Shirley poppies, larkspurs and cornflowers are all delightful denizens of the *pré fleuri*. I have just made such a one in the country not far from Paris. It is a sloping field with a tall hedge as a background and ends in the main sandy drive of the garden. Along the hedge I have planted white, yellow and red foxgloves. Down the slope, the plants get gradually shorter until they overflow into a rockwork border of many alpine plants but few rocks! The flatness of the meadow is broken by a tree or two. A silver birch half way down on one side of the slope, a Cornus mâle (with its mimosa-like flowers and attractive fruit) in the midst of the bulbs, and three Scotch firs *en marmite* on the right at a short distance from the hedge. Perhaps the chief fascination of a conceived alpine meadow is that, like an herbaceous border, its greatly to be envied owner can create it "to the *zest* of his mind."—VICTORIA SLADE.

SIMPLE GARDENING

CUTTING HEDGES.

HEDGES are either ornamental and useful and add to the attractiveness of a garden, or they are untidy, neglected, and detract from the general appearance. Privet hedges are useful and look well, too, in a suitable position where the roots will not interfere with garden crops or shrubs, trees or flowers. There is the evergreen and the variety that loses its leaves, or nearly all, in the winter months; but in the case of all privet hedges their good appearance during the wintertime depends very much upon their treatment at this season. I always make an effort to cut my privet hedges twice after midsummer—about the end of July and in October—then they remain green throughout the winter. If the shoots are allowed to grow long and then cut hard back late in the year, there will be much bareness of outer surface afterwards. These remarks apply to all evergreen hedges. Now, we should consider how to cut the hedges so that they will retain their natural form and appearance. Privet, thorn, plum and all small-leaved deciduous hedges should be cut with shears or "brushing-hook." But laurel and other large-leaved evergreen plants should be pruned, as it were—that is, the stems should be cut individually, then the leaves will not be mutilated and the outer surface will retain its natural appearance and not show signs of having been "clipped."

WALLFLOWERS AND SWEET WILLIAMS.

I daresay we all feel that it is a very easy matter to grow even thousands of plants of wallflowers and sweet williams. They are not difficult to grow, but I have found it a very difficult matter to induce many cultivators to take the proper amount of trouble with them so that they may be grown well. Usually, the seeds are sown thickly in narrow drills late in the summer. The result is that the plants, even if given the very best treatment, will not be satisfactory. We now deal with the seedlings resultant from a May or early June sowing. Such seedlings are now ready to be transplanted in a nursery bed 4ins. apart each way. Only moderately rich soil will be needed and the plants well watered several times afterwards. Owing to this early transplantation the roots of the wallflowers increase in number very much, and, as a consequence, the branches are more numerous and sturdier. Sweet williams should be planted deep enough to ensure steadiness, with the result that roots are plentiful from the basal leaves downwards, and this ensures a very sturdy upright growth. When the time comes to put out the spring-flowering and other plants it will be found that fifty of these carefully transplanted specimens will fill a border that would require a hundred or more of the weaklings from the seed-beds. Furthermore, the individual flowers are larger and the general display splendid.

"TAKING" CHRYSANTHEMUM BUD-CROWNS.

I prefer the words "selecting," "securing" or "retaining" the buds, rather than the word "taking." But as bud selecting has been generally referred to as "taking" the bud, I use it for our purpose now. The experienced cultivator knows all about the operation, the inexperienced does not. For the latter's benefit I have drawn a sketch which will, I hope, prove helpful. From late in July to the end of August the majority of the buds will be crowns—that is, a bud surrounded by young shoots. The latter should be removed gradually, not all at one time in one day, but during a week. No. 1 shows where a shoot has been pinched off; Nos. 2,2,2 are the remaining shoots to pinch off. The stem of the crown bud, No. 3, must not be damaged by hand, knife or insect or the bud will develop one-sided. No. 4 shows the bud swelling satisfactorily, and a keen watch should be the rule, especially at night, for earwigs, as they soon spoil a plump bud by eating out the centre.

SUMMER TREATMENT OF RASPBERRIES.

It is astonishing how many cultivators, especially those who have not had any practical experience, and some who have, fail to treat these plants as they should do during the hot days of summer. The summer-fruiting varieties require different treatment, to some extent, from the autumn-fruiting ones. To refer to the former first. Usually, the plantations become overcrowded with young sucker shoots, these growing up among the old fruit-bearing canes and, also, on both sides of them. Now, as raspberries are surface-rooting plants, it would be wrong to dig up the soil between the rows. On the other hand, it would be a mistake to cut off all surplus young suckers at the soil level. The old canes, directly the fruit has been gathered, should be cut out low down. All the weakly suckers should also be carefully pulled up. It may be necessary gently to ease up the soil around each one with a hand-fork. The fairly strong young suckers retained should be about 6ins. asunder. They will thus receive the maximum amount of light and air and so mature. The cultivator is thus providing for the next year's crop of fruit. There should not be any need to cut out surplus canes in winter. The autumn-fruiting plants should be left untouched beyond the removal of the outer, dwarf-growing sucker shoots to allow those retained, and bearing fruits, to ripen the latter. Retain all the fruit-bearing canes till late in the year.

RAISING SCHIZANTHUS PLANTS.

The present is a very suitable time to sow seeds of schizanthus. Probably, the cultivator will not require more than fifty plants, taking an approximate number, so that the extra trouble in raising seedlings, that I wish to advocate, will not be great, but the results in the form of fine specimen plants will be. I find it best to collect—for a batch of fifty plants—sixty quite small pots, to drop a tuft of fibrous turf in the bottom of each, no crocks, and to place these small pots in a shallow box quite close together. Then the pots are nearly filled with compost of equal parts of leaf-soil and fibrous loam and gently firmed. Several seeds are dropped near the centre and lightly covered. If the soil is watered in the pots before the seeds are sown the seedlings will soon appear. When the seedlings are growing freely remove all but one in each pot and re-pot before the plants weaken in the tiny pots. They do not receive any check and if given well ventilated positions on shelves in a greenhouse, they will form beautiful compact specimens. GEORGE GARNER.

GARDENING OF THE WEEK

FOR SOUTHERN GARDENS.

THE KITCHEN GARDEN.

Celery.—The crop should be examined occasionally, and useless leaves, weeds and side growths removed. Where paper collars are employed, additional ones may be required, and other plants may be earthed up when the weather is dry. A soaking of water and liquid manure should be given the day before such work is carried out. Later trenches should be kept well supplied with moisture, and any leaves attacked with the maggot pinched off, and an occasional dusting of soot given during showery weather.

Cabbages.—A liberal sowing of seed should be made during the next few days. If the ground is dry water the drills a few hours prior to placing the seeds therein. Protect them from birds.

Winter Onions are fit for the kitchen some weeks before the spring onions, so it will be necessary to sow seeds of one or two varieties about this date. The lines should be 1ft. apart and the seeds sown thinly. The seedlings should remain in the rows until the spring before being transplanted.

THE HARDY FRUIT GARDEN.

Strawberries.—The straw and decayed leaves should be removed from the strawberry bed, and the soil well hoed between the plants. Runners ought also to be cut away, if not required to make new plantations. Give the beds a sprinkling of some reliable fertiliser, and if a dry spell of weather sets in, a thorough watering will help to build up strong fruiting crowns for next year. Layers that were placed on pots of soil a few weeks ago may be severed from the parent plant, and new beds made. The ground should be trenched and a liberal dressing of manure given. Allow the soil to settle down, and before planting give it a treading over to make it firm for the plants. A distance of 2ft. should be allowed between the rows, and 18ins. between the plants. A deep loamy soil is best for strawberries, but where it is light and sandy, a good dressing of cow manure may be afforded. Most soils will benefit by a light sprinkling of lime. Planting should be completed as early in August as possible, spread out the roots, make the soil firm and provide a little shade if the sun is hot. Each evening a sprinkling of water will help the plants to become established.

THE FLOWER GARDEN.

Summer Bedding.—The plants in the beds will require attention occasionally, and to have all dead leaves and flowers removed. Tall-growing plants will need a stake, and the soil may be lightly hoed to keep down weeds. Seed pods should be picked off the sweet peas, thereby prolonging the flowering period.

Roses.—Those belonging to the rambler section may be pruned soon after the flowering season. The exact amount of pruning to be done, will depend on the varieties; such kinds as Dorothy Perkins thrive best if the old growths are cut out or reduced to a vigorous new shoot. Others may have their old flowers removed, and any young growths tied in, but where they are likely to be overcrowded some of the old wood may be dispensed with. Dead flowers should be picked off the hybrid perpetuals and others.

Lavender.—If it is desired to increase the stock, cuttings may be inserted in the open ground, placing a little sand in the soil which falls in the hole made for each shoot. Where the flowers are needed in a dry state, cut the spikes before all the blooms are open.

T. W. BRISCOE
(Gardener to W. R. Lysaght, Esq.),
Castleford, Chepstow, Gloucestershire.

FOR NORTHERN GARDENS.

THE KITCHEN GARDEN.

Brussels Sprouts.—Plants raised from seed this year and set out about the end of May or early in June, should be sufficiently advanced now to have the soil drawn up on either side of the stems. This will not only stir the soil and so retard the progress of weeds, but it will also help to keep the plants — especially in exposed places — in an upright position.

Cabbages.—All spent crops should be cleared from the ground and also anything left in the vegetable seed bed. A little cauliflower and lettuce seed—to provide plants for setting out early next year—should be sown on a south border.

Onions.—Those who desire to have onions for pulling early should sow seed now. There is no need to dig or manure the ground on which to sow provided this was done for a previous crop, such as early potatoes. Select a place on a south border, then hoe the surface and rake to level the soil and clear away weeds, this is really all the preparation the soil will require. Drills should then be drawn out about 2ins. deep and 1ft. apart and the seed of White Lisbon—which is one of the best varieties for early pulling—sown therein. Other kinds such as Ailsa Craig and Cranston's Excelsior to be transplanted in March or April of next year and grown for bulbing purposes may also be sown now.

Potatoes.—Large quantities of the early varieties will now have gone to the kitchen, and those who harvest their own "seed," should have the tubers—which were left for that purpose—lifted from the lines. Tubers for "seed," should be carefully selected, large and very small ones being rejected, and those of a medium size and good shape being retained. Each variety should be placed separately into boxes—ordinary cutting boxes will do—and properly labelled. The boxes should be left out of doors for some time and the tubers occasionally turned, so as to get them properly "greened," all over. Tubers of Epicure turn a very dark colour under this method.

Jerusalem Artichokes.—Where these plants do well they usually get very tall. A foot or more should therefore be taken from the top of each stem.

THE FLOWER GARDEN.

Delphiniums.—These plants have grown and flowered splendidly this year, having sent up many tall and stately stems. All stems which have borne flowers should be removed, so that the energy of the plant is not expended on seed bearing. Those, of course, who wish to increase any special favourite from seed would require to leave a few stems, until the seed was secured.

Narcissi.—Those having bulbs to plant in beds or in grass should make a start now. If holes are made with a trowel or bulb planter the work may be quite expeditiously done and the bulbs set out in any formation desired. Each bulb should be covered with 2ins. or 3ins. of soil.

THE HARDY FRUIT GARDEN.

Strawberries.—As soon as the crops are finished on the early plantation and those still to be retained for future cropping, the runners—if sufficient have been secured for fresh plantations—should be cut from each plant and with the old straw, they should be cleared away and burned.

DAVID ARMSTRONG
(Gardener to North More Nisbett, Esq.),
The Drum, Gilmerton, Midlothian.

FOR GREENHOUSE AND CONSERVATORY.

Humea elegans.—From now until the end of August seed of this plant may be sown in a cool greenhouse. H. elegans is generally regarded as being difficult to grow successfully. This is true as regards its final stages of cultivation, and care in watering is required. However, in its younger stages no difficulty should be experienced. Failure is generally due to keeping the young plants too close and warm; perfectly cool treatment in a light airy house is essential at all times. When large enough to handle, the young seedlings should be pricked off singly into thumb pots, potting them on as they require it. Early in the New Year the plants should be ready for a shift into 6in. pots, and later on into 8in. pots, in which fine specimens can be flowered. It is during their final potting that special care is required, and water should be very carefully supplied at the roots until they get a good hold of the fresh compost. They are somewhat liable to attack by aphis, which should be prevented by light fumigations. A compost consisting of a good medium loam with the addition of a little leaf-soil and enough sand to keep the whole open and porous is suitable for this plant.

Fuchsias.—Where large specimens are required for the greenhouse next summer they should be propagated by means of cuttings during September. To secure suitable cuttings for this purpose, the required number of stock plants should, at this time, be partly shortened back and started into growth in a warm greenhouse. The young growths produce roots very readily, and the young plants should be grown on steadily all through the winter, potting them on as they require it. By this method fine specimens 7ft. to 8ft. high can be produced by July and August next year. The leading shoot should be kept tied up to a stake, and not stopped, as they will produce lateral growths naturally. They should not be pinched until some six weeks before the plants are required to flower. If standards are required the main shoot should be kept tied up to a stake, rubbing out all lateral shoots as they appear, until the desired height is attained, then stop the leading shoot.

Cyrtanthus.—This genus of South African bulbs is deserving of more general cultivation, as they only require cool greenhouse treatment. There are some fifteen species, but only three or four are in general cultivation, viz., CC. lutescens, Macowanii, Mackenii and sanguineus. The bulbs can generally be purchased dry during autumn, but under cultivation they should never be dried off altogether, as they are more or less evergreen. The best results are obtained by placing five or six bulbs in a 5in. or 6in. pot. They grow quite well in any good potting compost, but with newly potted plants water should be very sparingly supplied until they have made fresh roots and got well away in the fresh compost.

Desfontainea spinosa.—This beautiful plant when out of flower is often mistaken for a holly. It is hardy in the West, but in the colder parts of the country should be more generally grown in the cool conservatory, where it is seen to best advantage when planted out in a well drained bed. It produces its tubular scarlet and yellow flowers over a long period. Cuttings of half-ripened shoots root readily in sandy soil. Stand the cutting pots under a bell glass in a cool greenhouse or cold frame.

MAGENTA

IT is an interesting sign of a changing point of view that magenta is once again becoming a fashionable colour, for the prejudice against it has been so strong these last thirty years that the mere mandate of a fashion maker would hardly have prevailed if the feeling of people in general had not lent facility.

Hall-marked with vulgarity, it was rightly banned as a quite impossible colour by everyone, except by a few painters who were suspected of being deliberately eccentric. No other colour seemed to evoke such strong feeling, and it may be reasonably assumed that the feeling was not purely æsthetic, but due chiefly to its association with the mid-Victorian period when it was last fashionable. It seems to be a general law that we react against the taste of our parents, and against the taste of Victorian parents the reaction was very strong and emphatic. But the present generation has no personal memories of magenta in the setting of Victorian domestic life, and it seems to have become a little impatient of those soft, sometimes even dingy, colours that are, curiously, called "art shades"; so that, if we allow something for this last reaction, it is now possible to look at magenta with a fairly dispassionate eye and to get some measure of its æsthetic value.

Even during the hey-day of its unpopularity the offensive colour was, significantly, more easily tolerated in natural than artificial surroundings, and although magenta as a colour description disappeared from the catalogues, yet magenta-coloured flowers remained in fair demand if they were discreetly listed as "amaranth" or "glowing crimson." It had been appreciated for a long time that magenta flowers became a fine red by artificial light, while crimson and scarlet took on a sombre, blackish tone; but quite apart from this accidental advantage the colour retained a place in the flower garden, and two families of steadily rising popularity, the primulas and rhododendrons, continued to add to it. When Primula Juliæ arrived from the Caucasus and settled down so happily in our gardens, covering its hummocks of dark green leaves with brilliant magenta primroses, it was given a very warm welcome and nothing was said against its colour.

The incompatibility of magenta was the chief objection to it, if we set aside the epithets "crude" and "virulent" as expressions of merely personal distaste. This objection would be more serious if the plants themselves did not provide, so often, an admirable setting of grey or dark green leaves, and there are surely occasions when the passion for combinations of brilliant colours need not dictate. Magenta is not an easy-going, companionable colour, but its incompatibility has been rather exaggerated; there is no denying, for example, the brilliance that it adds to a bunch of purple and violet sweet peas or to a group of red polyanthuses. For it has a peculiar luminous quality, hardly matched by any of the pure colours, which is well seen in Cyclamen Coum, glittering in the pale sunshine of February, or the fierce intensity of a clump of Lychnis Viscaria in a half-shaded border.

Perhaps its most interesting combination is a dull gold or an ochreous yellow with a really vivid magenta, the pale biscuit-coloured annual nasturtium provides just the right ground colour, and it may also be found in some of the new lupins. The curious pale green of Helleborus lividus seems to invite a trial with magenta, and next spring will show whether Peonia corallina and P. tenuifolia, which vary a good deal in their "crimson," can provide the right tone. We are never likely to let magenta flood the garden, but it has a very definite value within certain circumstances, and it is interesting to see it coming into play.—F. A. HAMPTON.

BOOK REVIEW

HORTICULTURISTS are becoming less conservative every day now and it will no doubt be pleasing to many to see a new and somewhat unique publication in the form of "The Cultivation of New Zealand Plants," by Dr. L. Cockayne (Whitcombe and Tombs, Limited, New Zealand), price 4s. 6d., which deals solely with the plants from "down under," as the name implies. One need not discuss at length the merits of this little book. The name of such a well known author and botanist stands as a criterion of its quality. Probably no other man has such a wide and varied knowledge of the New Zealand flora as Dr. Cockayne, and he is equally at home when describing and dealing with garden plants and their propagation. The present little booklet is the outcome of some thirty-five years experience with New Zealand plants and as such should be of valuable assistance to those in doubt as to the best species to grow. Many could be tried in this country with good results. The style is simple and lucid, yet captivating and instructive, and the amateur should find no difficulty in following the text. The book is clear and nicely printed and shows every care in compilation, being free from errors in nomenclature.—G. C. T.

OBITUARY

ANTHONY WATERER.

JUST as we are going to press we have been informed of the death, on July 24th, of Mr. Anthony Waterer, proprietor of the world-famous nursery at Knaphill, Surrey. His name is especially well-known in connection with the raising of choice hybrid rhododendrons and azaleas, and he probably did as much to popularise the genus rhododendron as any man of this generation. Like the equally famous Bagshot house of John Waterer and Sons (now J. Waterer, Sons and Crisp), the Knaphill firm always steadfastly refused to send out hybrids which were not absolutely hardy in every part of the country. We are sure that our readers will share our regret at the passing of yet another of the little band who helped to lift British horticulture to the proud place it occupies at present.

DR. ROBERT KIDSTON.

IT is with much regret that our readers will learn of the death, which took place the other day, of Dr. Robert Kidston, the well known authority on the fossils of the carboniferous period and a botanist of the highest attainments. Dr. Kidston was equally interested in living plants and in his beautiful garden at Clarendon Place, Stirling, he grew many border and alpine plants. His extensive rock garden is well known to many visitors. Dr. Kidston was one of the kindest and most respected of men and his death is deeply lamented.

TRADE NOTE

A NOVEL WATERING CAN.

A watering can is used by Messrs. Corry and Co. for packing their insecticides, washes, weed killers, etc.—instead of the ordinary tin, which is useless when empty—and is given away by them. These cans alone are worth 2s., 3s. and 4s. each to the buyer, and they are given free with half gallon, one gallon and two gallon sizes. The cans are well made, with detachable spouts. When required as a watering can, the spout is screwed in its position at the base after the can has been emptied of its original contents.

ANSWERS TO CORRESPONDENTS

THE FLOWER GARDEN.

Clarkia Plants Dying (H. J. R.).—The plants have died owing to an attack of the fungus Pythium de Baryanum. This disease is generally accompanied by a greyish-coloured, web-like substance on the soil and around the roots. It was present on the roots of the plants sent. Too much moisture, at some stage of the plants' growth, is the general cause. The soil sent for examination lacks lime. This may be remedied next autumn by adding some or lime rubble from old walls taken down.

Dianthi for Identification (" Dianthus ").—The dianthi sent for identification are seedlings. A. is a seedling from Dianthus monspessulanus alpestris and is a very good form, but slightly taller in habit than the type. B. is a seedling from D. glacialis, and C. from D. barbatus. One of the aggravating things about dianthi seedlings is that one gets such a multitude of them which are very little better than the original species and none of the specialists seems to have made great headway in the improvement in rock varieties of dianthi.

Peonia Stem Dying (W. B., Oxon.).—There were no grubs to be found in the stem enclosed for examination The stem appears to have received an injury from some cause or it may have suffered from frost and the maggots entered the decaying stem afterwards. It would have been more satisfactory to have sent a larger portion of stem and some grubs secured in a tiny bottle for examination.

TREES AND SHRUBS.

Olearia (J. M.).—The correct name of the specimen sent, with two photographs, is Olearia Gunniana. The shrub is often grown in gardens as O. stellulata, but the plant originally described under this name by De Candolle is more open in habit, with larger leaves up to 4ins. long, and larger flowers. In the first edition of " Trees and Shrubs," by W. J. Bean, the plant sent is figured and described as O. stellulata, but in the second edition the correct name of O. Gunniana is given. Mr. Bean explains the mix-up as due to Bentham uniting the two. There may not be much difference botanically, but cultivated in pots or in warm sheltered positions outside they are very distinct. In the southern and western counties, in various parts of Ireland and the west of Scotland, some ten or twelve species of olearia are grown in the open. These include OO. Forsteri, insignis, albida, macrodonta, erubescens and the subject of this note.

FRUIT GARDEN.

Fig Tree not Ripening Its Fruits (Mrs. E.).—Although a fig tree produces three crops of embryo fruits each year, only one matures in the open air in this country. The first tiny fruits are formed on the shoots of the previous year's growth, the following crops do not go further than the embryo stage and should be pulled off. In spring the tips, only, of the shoots bearing the young fruits should be pinched off. This will have the effect of causing the fruits to swell and if water be applied liberally in dry spells then, if the tree is growing in a sunny position, a fair crop of ripe figs should result.

Peach Tree Cankered (H. S.).—If the tree is old and badly cankered the wisest thing to do is to remove it and the soil about the roots and plant a young one in November. If it is not old and gummed, not cankered, then cut out the bad parts and train in young wood next year—the medium-strength shoots, not the strong ones. Remove the latter by disbudding in a young state.

Gooseberry Mildew (D. C., Dunsfold).—The berries are almost covered with the mildew in its worst form. For our correspondent's own protection in the future the bushes affected should be dug up, and the roots as well as the branches and stems burned. Apply 6oz. per square yard of gas lime on that particular quarter and leave the soil uncropped till next spring. Carefully watch the remaining bushes as it is quite useless retaining any that are diseased. Plant new ones in another part of the garden.

About Gooseberries and Black Currants (" Limington ").—If the gas-lime is applied to the ground in which the gooseberries have been growing straight away, the black currant bushes may be planted early in November with perfect safety.

Strawberries not Fruiting Satisfactorily (J. P.).—Undoubtedly some of the flowers were frozen, and, furthermore, the stock was raised by layering from unsuitable parent plants. Although the plants were treated well, a good average crop of berries would not result in the circumstances. Procure a new stock of young plants as early as possible, now, and allow fruits, in reason, to ripen on them next year.

Gooseberry Bushes Attacked (E. W., Somerset).—The caterpillar attacking the gooseberry bushes is that of the gooseberry sawfly, Nematus ribesia, which is a common and destructive pest throughout the greater part of the British Isles, and is quite common on black currants, red currants and gooseberries. It is a pest which increases steadily whenever it is neglected. The cocoons remain in the soil during the winter, and produce the adult flies in the following spring. We advise our correspondent to deal with small attacks, otherwise it is almost certain that serious trouble will follow. Hand picking is the simplest method in the case of a few bushes, but it should be done before the young larvæ have scattered on the bush. Some may prefer to pick the leaves on which the eggs have been laid. Spraying is thoroughly effective against this pest. The chief difficulty lies in the fact that the best washes are poisonous. Lead arsenate may be used in the case of early attack, where it can be applied before the gooseberry flowers appear and also after the fruits have been gathered. Hellebore, when fresh, and nicotine are also effective and, though poisonous, do not retain this quality for long. They may, therefore, be used with safety if an interval of three weeks be allowed between spraying and picking.

There are also a number of proprietary brands of insecticides on the market which can be recommended for small gardens.

VEGETABLES UNDER GLASS.

Tomato Foliage Attacked (A. H.).—No doubt the growing of tomatoes and melons together last year pre-disposed the crop of tomatoes this year to the disease as the spores of this disease, Dactylium roseum, germinate on the plants, soil or woodwork. The only remedy at this stage is to use dry flour of sulphur dashed on the leaves, to cut off and burn the badly-diseased leaves, to be careful in watering and admit abundance of air, night and day. Next year use fresh soil after thoroughly washing the interior of the woodwork with an insecticide and lime-washing the walls.

Tomato Plants Unsatisfactory (" Cheshire ").—The plants, judging from the leaf sent for examination, are not diseased. The leaves have curled because green aphides have attacked them on the undersides. Aphides were present on the leaf examined, but these insects were more numerous a month ago and so caused the leaves to curl. The plants have been treated too generously and are the result of a bad strain of seed, which mainly accounts for the poor crop of fruits. We suggest that our correspondent buys seeds from a good firm of seedsmen next year and burn all his own plants when the tomatoes have ripened.

MISCELLANEOUS.

Solomon's Seal Foliage Attacked (Mrs. E. W. M.).—The caterpillars sent are those of the sawfly. They are most voracious and assume, to a great extent, the colour of the foliage on which they feed. Throw soot or dry lime, separately, not together, nor at the same time, on the plants. Also syringe with Abol according to the instructions given with this insecticide and mildew remedy.

Insects at Roots of Plants (G. M.).—The insects sent for identification are woodlice and the flattened millepede, Polydesmus complanatus. A fair dressing of common salt will kill these millepedes, also an application of nitrate of soda in solution, one ounce to three gallons of water. There must be moisture with the salts and a common brine solution, one pound of salt to ten gallons of water, would answer without doing harm to the plants. The woodlice are not doing the mischief. But the soil is very sour and quite fibreless. It needs a dressing of lime in the autumn, quite two pecks per rod of ground.

Bog Garden (A. M. C.).—The situation of the proposed bog garden does not sound very promising with the hedge on one side and a tree on the other. But it can be converted from a water tank into a bog garden very easily. It is necessary to have an overflow in order to take off the superfluous water and keep it sweet. Put 3ins. of drainage in the bottom, cover this with thin turves placed upside down, and on top fill up with a mixture of loam and sand. Only small plants can be grown in a garden of this size, like Primula rosea, P. involucrata, P. Wardii, Saxifraga aizoides, Parnassia palustris, Myosotis Rehsteineri, and others of similar nature, or the large ones will crowd out the choicer plants.

Table Decorations (E. S., Reading).—It is exceedingly difficult to give our correspondent any advice upon table decoration as, for one thing, he does not mention the names of the flowers he proposes to use. The great thing is not to have too many blooms in the decoration, and so make the arrangement crowded. Another thing is to avoid violent colours. Yellows and blues go well together; mauves and whites and so on; but the art of table decoration is an entirely personal one, and is, of course, akin to the artistic sense.

Name of Plant.—(Charts Edge).—Rosa moschata alba.

ROBERT FORTUNE

A GREAT deal has been heard within the past twenty years of new introductions from China to our gardens, so much so that some of the older collectors have gradually passed into oblivion. Their memory only remains in an occasional plant called after them. Many people know a conifer called Cunninghamia sinensis, but few know that the genus Cunninghamia was named after a Scotch surgeon called James Cunningham, who was one of the first, if not the very first, collector of plants in China, and that at the end of the seventeenth century.

It may be pardonable that his name be forgotten, for his researches did little towards improving our gardens, but it is unpardonable that the name of Robert Fortune should be allowed to fall into oblivion, for Fortune, apart from the valuable garden plants he introduced from China, some of which I will mention later, laid the foundation of the gigantic tea industry of India and Ceylon. Not only did he study the cultivation of tea and write several books dealing with the subject, but he also was in charge of the herculean task of transplanting 20,000 tea plants in Wardian cases from Shanghai to the Himalayas, a notable achievement.

Robert Fortune was born in Berwickshire in 1813 and served his apprenticeship in the Edinburgh Botanic Gardens. He then entered the services of the Royal Horticultural Society, under whose auspices he made his first journey to China from 1843-45. He made subsequent journeys in 1848-51, 1853-56 and 1860-61; in the course of the last journey he visited Japan. Apart from miscellaneous papers, he published narratives of each of his voyages, which are interesting reading, but uninspired. It is difficult to form an estimate of his character from his writings, except that he must have been a very canny Scot. In speaking of the Chinese he says, "In fact, latterly I made a practice of disbelieving everything they told me, until I had an opportunity of seeing and judging for myself." Obviously a case of once bitten twice shy. However, he was a careful and skilful observer and like many of our race he was not satisfied with seeing; he wanted to know the reason of what he saw. Usually he got his way, but how the Chinese must have hated him in the process.

The reason for this reminder of the existence of Robert Fortune is that I was asked the other day why Rose Fortune's Yellow was called Fortune's Yellow. My questioner had some idea at the back of his mind that there was some mythological story attached to its nomenclature and was rather annoyed to find that it was only called after somebody. Incidentally there are two Fortune's roses, both from China. According to Mr. Bean one is supposed to be a cross between R. Banksiæ and R. lævigata, the other, yellow variety is a form of R. indica.

Fortune was the discoverer and introducer of such well known plants in our gardens as Skimmia Fortunei, Prunus triloba, Viburnum macrocephalum and V. tomentosum var. plicatum, Lonicera Maacki (this he did not introduce), and L. Standishii, Rhododendron Fortunei and several forms of R. indicum, Forsythia viridissima, Jasminum nudiflorum, and so on. He also was the first to introduce Pinus Bungeana, Cryptomeria japonica and Primula japonica.

The main reason for his journey to Japan was to get a male plant of Aucuba japonica. Female plants had been introduced in 1783, but of course, would not berry; his object was to make up this deficiency; surely a long journey to obtain this horrid plant. It is the only grudge I have against Mr. Fortune.

On reading his works and about his exploits, I have been more struck by his successful use of Wardian cases for the transport of plants to England than by anything else. Before their introduction apparently the average survivors of a long voyage were one in a thousand, and with such results, the voyage was hardly worth the trouble. By the introduction of the Wardian case Fortune managed to send home an enormous number of plants alive; in one shipment of 250 plants there were only 35 deaths, surely a good advertisement for that method of transplanting plants alive—and that was in the days of slow travel.

Perhaps in these few notes it will be seen that Robert Fortune is worthy of a place in that great band of Chinese collectors who have done so much in the way of introducing worthy plants to our gardens.

CEANOTHUSES

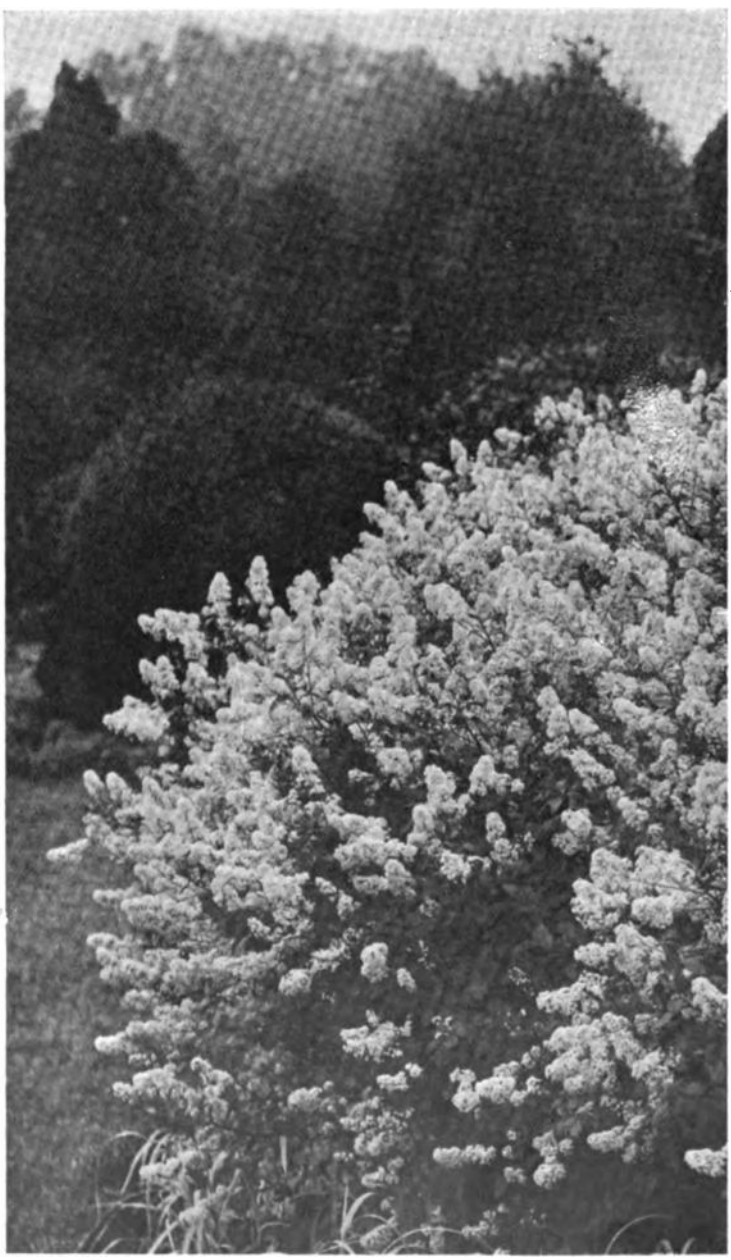
BY W. J. BEAN.

THESE FREE-FLOWERING SHRUBS ARE ESPECIALLY VALUABLE FOR THEIR LATE FLOWERING.

ALTHOUGH blueness is not a uniform characteristic of the flowers of the ceanothuses, it is a prevailing one, and so uncommon is the colour among hardy trees and shrubs that it imparts a special value to this genus in gardens. A recent picture in these pages of C. rigidus in the Royal Botanic Gardens, Kew (see THE GARDEN, June 14th, 1924)—a plant apparently about 10ft. high covered with blossom—gives, if one can imagine the blue colouring, some idea of the effect that can be produced by one of the best of these shrubs. The genus is exclusively North American, and the finest kinds come from the Pacific coast region, chiefly from California.

Except that some of them are tender and some transplant badly, they are quite easy to cultivate. They prefer a light, well drained soil rather than a heavy one, and should be grown fully exposed to the sun. The difficulty in regard to transplanting is got over by putting them in their destined places early and growing them in pots until this is done. Nurserymen, fortunately, realise this and all who know their business supply in pots stock of these bad-shifters. In the extreme south and south-western counties the tender species can be grown fully in the open; but near London and farther north wall space has to be provided. A south wall is to be preferred or one facing west, but if an east wall is the only one available it may be used. A list of the kinds that are worth growing and need such protection is as follows: azureus dentatus, integerrimus, Lobbianus, papillosus, rigidus, Veitchianus and velutinus.

But wall space is often scarce, and where it is not to be had a very attractive selection of ceanothuses may still be grown. C. thyrsiflorus is one of them; there has been for forty years a large group of it near the Broad Walk at Kew. But apart from that species one has to rely mainly on a group of hybrids that have been raised from CC. americanus, azureus and ovatus, the first and last of which are hardy. These hybrids are bushes more or less deciduous and usually 3ft. to 4ft. high, although, if unpruned, some will grow 2ft. or more higher, especially in mild districts. They also transplant well enough in the small state for pot culture to be dispensed with. M. Lemoine of Nancy deserves honourable mention for his work in hybridising this group, the value of which as ornamental shrubs is enhanced by their flowering from June onwards to October. Perhaps the best of the blue-flowered varieties is the well-known Gloire de Versailles, a hardy free-growing shrub with richly coloured flowers, of which a succession is produced from now until the early frosts of autumn. Other good varieties are Gloire de Plantières (blue), Indigo (a very deep blue, but not very hardy), Lucie Simon (light blue), Léon Simon (light blue), Gay-Lussac (violet-blue), Virginal (pure white), Le Géant (large trusses of white flowers), Perle Rose (pale rose), Mérimée (soft rose), Georges Simon (rosy lilac) and Président Reveil (pink). As all of this americanus-azureus group flower on the current season's growth, they can be pruned back almost to the old wood in March and thus kept comparatively small for a good many years. Those that flower earlier and from the growths made the previous year need pruning as soon as the flowers are over if the plants are given wall protection. But if, like C. thyrsiflorus near London, they can be grown fully in the open, they need not be pruned at all except when one may wish to correct some unshapeliness. All the ceanothuses can be propagated by means of cuttings made of short, firm side shoots during late July and August. They should be put in pots of very sandy soil and given the mild bottom heat of the propagating case.



ONE OF THE BEST OF THE BLUE-FLOWERED VARIETIES, C. GLOIRE DE VERSAILLES.

C. rigidus is one of the richly blue-flowered species and is readily distinguished from all the rest by having opposite leaves, that is, they are set on the stem in pairs. They are quite small, only ¼in. to ½in. long, but densely packed on the branchlets. Last year, owing no doubt to the dull cool weather, this species kept up its floral display for six weeks—from early May well into June.

Another well marked species of great beauty is C. papillosus, so called from the wart-like protuberances (or papillæ) on the upper side of the leaf, which is oblong and varies from ½in. to 2ins. in length. The flowers come in May in cylindrical racemes up to 1½ins. long, very abundant and of a charming blue.

I have already mentioned C. thyrsiflorus, and for the average climate of Great Britain no ceanothus to my mind is equal to it, although its flowers are of a paler hue than those of rigidus or papillosus. Its hardiness is its first great asset, and it is only severe and continued frost that seriously affects it. During the more than thirty years I have grown it without protection it has only

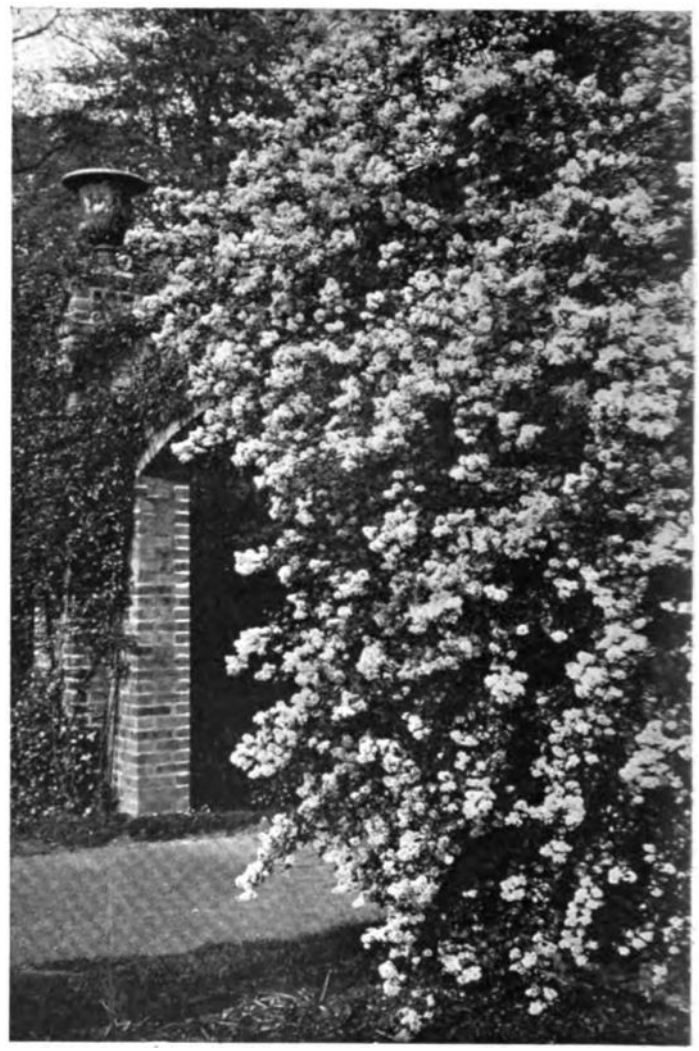
suffered once, which was during the February cold of 1895. Then, among blue-flowered shrubs, its size gives it distinction and prominence. It is often a tree in a wild state over 30ft. high with a trunk 1ft. or more in diameter. Even at Kew I have known it over 20ft. high grown in high shrubbery. It is readily distinguished by its angular branches and by the three conspicuous veins at the base of the leaf. It is evidently variable in the colour of its flowers. Sargent describes them as " blue or white." I have not seen any white ones, but there is a variety called griseus which has pale greyish blue or lilac blossoms and larger leaves. It is an attractive shrub, but not so hardy as the blue-flowered type.

Three ceanothuses, so much confused in nurseries that one can never be certain which of them will be supplied under a given name, are dentatus, Lobbianus and Veitchianus, the two last of which are natural hybrids with thyrsiflorus as one parent. All three are beautiful shrubs with alternate leaves and bright blue flowers, and there is not much to choose between them in that respect. It is somewhat difficult to distinguish them shortly in words, but C. dentatus is marked by the veins of the leaf coming pinnately (*i.e.*, featherwise) from the midrib and by having no suggestion of the three prominent veins at the base that distinguish thyrsiflorus and its derivatives. Veitchianus is to be distinguished by the smooth stalks of the individual flowers, Lobbianus by the downy flower-stalks and more distinctly, more uniformly three-veined leaves. The last-named is, perhaps, the handsomest of the three and, like Veitchianus, has inherited from thyrsiflorus sufficient hardiness to enable it to be grown without wall protection in districts slightly milder than the home counties.

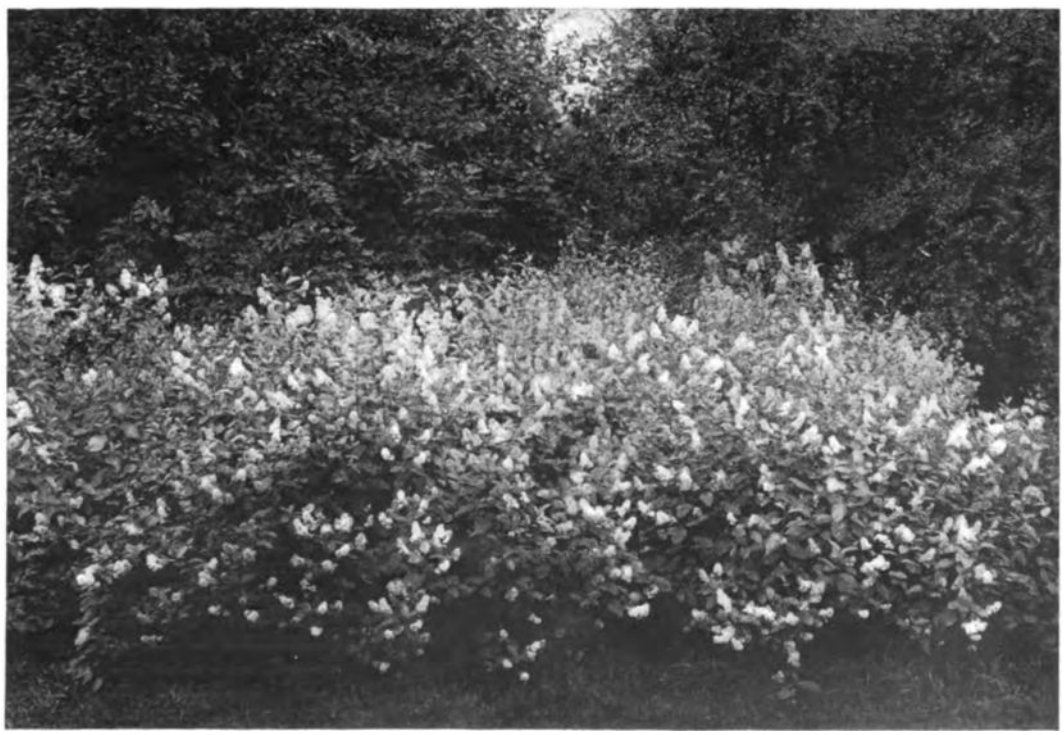
C. velutinus has prominently three-veined leaves up to 3ins. long and 2ins. wide, larger than those of any other species we grow in this country, very glossy, dark green and handsome. The bloom, however, is not particularly attractive, being dull white. This shrub needs wall protection and in the growing season has a resinous odour.

C. azureus, also a tender shrub introduced from Mexico over one hundred years ago, is probably not now in cultivation, although it has left its mark as one of the parents of the group of deciduous hybrids mentioned above.

Occasionally one sees a ceanothus labelled " floribundus " in nurseries and gardens, but, personally, I have never encountered the real plant of that name. It was discovered by Wm. Lobb when collecting in California for Veitch, and was figured in the *Botanical Magazine* in 1854. I doubt if this very beautiful shrub, with mazarine-blue flowers, is now in existence in this country.



C. THYRSIFLORUS GRISEUS, MAKES AN EXCELLENT WALL SHRUB.



C. AZUREUS, ONE OF THE PARENTS OF THE DECIDUOUS HYBRIDS.

To conclude these notes I may mention C. integerrimus, a June-flowering species, vigorous and free-flowering, but needing a wall. It has leaves nearly as large as those of C. velutinus and equally strongly three-veined, but they are dull greyish green. Its blossoms are pale blue or almost white, produced in panicles up to 1ft. long and 3ins. or 4ins. wide. A very effective shrub.

There are many other fine and distinctive species described from California but the ones selected and described will serve to illustrate the value of this genus as decorative and hardy shrubs for all garden purposes. They harmonise well with their surroundings and in summer lend a charming colour effect with their panicles of bright and pale blue flowers.

HERBACEOUS PHLOXES

AS THE PLANTING SEASON IS GRADUALLY DRAWING NEAR, THESE FEW REMARKS ON THE CULTIVATION AND GENERAL TREATMENT OF THESE BEAUTIFUL FLOWERING PLANTS MAY NOT BE INOPPORTUNE.

IT is doubtful whether any other hardy perennial for garden decoration excels the phlox. Coming into flower in July, the plant carries on well into the autumn, thus serving as a decided adjunct to the herbaceous border and the flower garden when other flowers, especially those with bright colourings, are beginning to become scarce.

The family consists of about forty-eight species, as defined by Brand, one of which is Siberian (P. sibirica) and the others all North American. These occur in a wild state in woods and thickets, on the prairies and plains, some of them alpine and arctic. One can thus recognise the extraordinarily varied range and distribution of the genus and how it can accommodate itself to such enormous changes both in climatic and topographical conditions. It is thus but natural that this flower has played such a prominent part in giving us the beautiful florist's varieties which we prize so much to-day. The herbaceous phlox has achieved a large measure of popularity during the last few years, but it is still not so widely cultivated as its merits deserve. This may, in some measure, be due to the fact that few people realise how long its flowering period extends and how numerous are its varieties. These many beautiful garden forms constitute a prominent feature in gardening, either planted in groups in the herbaceous border, or placed by themselves in beds in half-shady situations.

These phloxes are not fastidious plants, but should be provided with a well cultivated position. A rich and rather moist loam, deeply dug, with a fairly heavy dressing of well decomposed stable or cow manure, will suit the phlox admirably. They should never suffer for moisture or food, as they are rather shallow rooting, very gross feeders and intolerant of drought.

If planted in the herbaceous border, special attention should be given to them most seasons, unless the soil is a rich greasy loam; but they are easier to attend to and generally do better when given quarters to themselves. Given an abundance of moisture at the root, they do not object to sun-heat, although the colours may fade in the strong sunlight. They are less troublesome to grow in a border with a north and west aspect and preferably backed by a wall. Hedges and trees in the vicinity should be avoided, as their roots attract much food material from the soil and it is next to impossible to maintain an adequate supply of moisture.

For high satisfaction in bloom, the plants should be relatively young, or at least fairly often renewed by dividing the clumps. The stool gradually enlarges outwards. The new plants should be raised from the young vigorous shoots on the outside, if one desires to propagate the variety to any extent. Old stools should be taken up every year or two, divided and transplanted. This should be done in the autumn after all growth has ceased. Planting should also be carried out at this time, as the plants are enabled to get a firm grip of the soil before the winter cold sets in. By this process the plants do not become weak or root-bound.
